Swaging. Swaging Practice—III (Plaudereien aus der Gesenkschmiede), Paul Heinrich Schweissguth. Zeit. des Vereines deutscher Ingenieure, vol. 65, no. 12, Mar. 19, 1921, pp. 292–294, 48 figs. Shows how by folding and curling up finished metal articles, novel methods as to forming them from raw material may be developed. Pitchforks, carriage-top hardware and grubbing hoes used as examples of the value of method.

FORGING MACHINES

Nuts and Rivets. A Nut and Rivet Forging Machine. Eng. Production, vol. 2, no. 30, April 28, 1921, pp. 543–544, 2 figs. Design for quantity production.

FORGING PLANTS

Layout. Shop Well Planned for Material Handling, Gilbert L. Lacher. Iron Age, vol. 107, no. 18, May 5, 1921, pp. 1159–1162, 5 figs. Layout of plant of Kropp Forge Co., Cicero, Ill.

FORMING TOOLS

Straight. Dimensions of Straight Forming Tools. Machy. (Lond.), vol. 18, no. 448, April 28, 1921, pp. 103–107, 1 fig. Tables giving depth of steps on straight forming tools measured at right angles to front face, corresponding to various differences between radii on work.

FOUNDRIES

Austria. The New Foundry Plant of the Automobile Department of the Austrian Munition Works in Steyr [Das neue Gusswerk der Oesterreichischen Waffenfabriksgesellschaft (Automobilabteilung) in Steyr], Carl Irresberger. Stahl u. Eisen, vol. 41, nos. 4, 9 and 12, Jan. 27, Mar. 3 and 24, 1921, pp. 105–110, 288–293 and 401–406, 36 figs. Plans were drawn on basis of a daily production of the total requirement of gray-iron, aluminum, brass, bronze and white-iron castings for at least 60 automobiles besides a yearly production of 800 to 1000 tons of machine-tool castings in pieces weighing up to 5 tons. Plant is divided into three parts, an automobile gray-iron casting, an aluminum and brass casting, and a machine-tool casting department.

Design. Foundry Design Needs Study, J. H. Hopp. Foundry, vol. 49, no. 9, May 1, 1921, pp. 345–347. Foundry buildings should be designed with view of coördinating structure with demands of operation and protecting equipment against elements. Paper read before Am. Foundrymen's Assn.

Equipment. A Modern American Foundry. Eng. Production, vol. 2, no. 29, April 21, 1921, pp. 507–510, 4 figs. Equipment and labor saving devices at foundry of Lycoming Motors Corp., Williamsport, Pa.

Malleable-Iron. Changing Losses to Profits in a New England Casting Plant, Herbert R. Simonds. Iron Trade Rev., vol. 68, no. 18, May 5, 1921, pp. 1237–1243, 13 figs. Reconstruction and reorganization of malleable iron foundry. System for recording operations is feature.

Metal. Utilization of Scrap and Residues in Metal Foundries—I, C. Diegel. Metal Industry (N.Y.), vol. 19, no. 5, May 1921, pp. 196–197. German practice. Translated from Betrieb.

Mold-Drying Ovens. The Voith Mold-Drying Oven Fired with Low-Grade Fuels (Die Voith'sche Trockenkammerfeurung fur minderwertige Brennstoffe), H. Adämmer. Stahl u. Eisen, vol. 41, no. 12, Mar. 24, 1921, pp. 399–401, 4 figs. Details of arrangement and operation of mold-drying ovens of the J. M. Voith Machine Works, Heidenheim, Germany, using good coke and also low-grade coke-lignite or coke breeze.

Navy Yard. Navy Foundry Covers Wide Range, S. W. Brinson. Foundry, vol. 49, no. 9, May 1, 1921, pp. 335–341, 11 figs. Shop at Norfolk is equipped to handle gray-iron, steel and non-ferrous castings. Handling facilities provided to care for materials.

FURNACES, ANNEALING

Electric. Electricity Applied to Annealing, George P. Mills. Foundry, vol. 49, no. 9, May 1, 1921, pp. 366–368. Pit furnaces heated electrically by means of resistance ribbon are described. Pyrometric control with either single or double-point recorder regulates temperature closely.

FURNACES, BOILER

Low-Grade-Fuel. Steam-Boiler Furnaces (Dampfkesselfeuerungen), H. Berner. Zeit. des Vereines deutscher Ingenieure, vol. 65, no 15, Apr. 9, 1921, pp. 371–375, 8 figs. Change in requirements of furnaces due to use of low-grade fuels; combustion process and performance of low-grade fuels; the mechanical draft; change in furnace losses. Notes on horizontal and traveling grates; special furnaces for peat, wood and lignite, etc.

Rotary. Rotary Furnaces for the Economic Combustion of Coal Having Large Ash Content (Foyer rotatif pour la combustion économique des charbons très cendreux), L. Poirson. Chaleur & Industrie, vol. 2, no. 3, Mar. 1921, pp. 120–124, 6 figs. Grating is formed by inclined cylinder which is continuously rotating. Coal is burned inside cylinder.

FURNACES, HEATING

Sheet Bar vs. Mill Type. Heating Furnaces and Annealing Furnaces, W. Trinks. Blast Furnace & Steel Plant, vol. 9, no. 5, May 1921, pp. 305–308, 7 figs. Critical comparison of pair (sheet bar) and of mill type furnaces. Sheet bar furnaces are continuous.

Sheet Furnaces. Heating Furnaces and Annealing Furnaces, W. Trinks. Forging & Heat Treating, vol. 7, no. 4, April 1921, pp. 222–227, 10 figs. Comparison of different types of sheet furnaces.

FURNACES, HEAT-TREATING

Car vs. Car-and-Ball. Car and Car-and-Ball Furnaces. Machy. (N.Y.), vol. 27, no. 9, May 1921, pp. 873–875, 5 figs. Relative merits of heat-treating furnaces of car and car-and-ball types.

G

GAGES

Gage Blocks. Interference Methods for the Investigation of Gage Blocks (Interferenzmethoden zur Untersuchung von Endmassen), G. Berndt. Betrieb, vol. 3, no. 14, Apr. 10, 1921, pp. 389–396, 20 figs. Notes on origin of interferences of equal thickness and their use in investigation of smoothness of surfaces and for measurement of differences in length (methods of Bureau of Standards, of Köster, and Göpel); absolute determination of length with interferences of equal thickness; interferences of equal inclination and their use in measurement technique. Definition of length of gage blocks.

Manufacture. A Modern Jig and Tool Works. Automobile Engr., vol. 11, no. 149, April 1921, pp. 138–141, 11 figs. Manufacture of precision gages and tool making at Robinhood Eng. Works, London.

Screw-Thread. The Manufacture of British Association Screw-Thread Gauges, T. Farrance Davey. Jl. Instn. Mech. Engrs., no. 3, April 1921, pp. 191–196. Design, methods and apparatus used in measurement, compensation and correction for errors in lathe, cutting tools, lapping, and heat treatment.

GAGING

Limit. The Principles of Limit Gauging, A. A. Remington. Engineering, vol. 111, nos. 2885 and 2886, April 15 and 22, 1921, pp. 441–443, 7 figs., and 480–482, 5 figs. Attempt to build up logical system of limit gaging from first principles. Exposition of Newall standard system, extensively used in England.

GALVANIZING

Developments. 60 Years Progress in Galvanizing, Clement F. Poppleton. Iron Trade Rev., vol. 68, no. 17, April 28, 1921, pp. 1170–1174, 4 figs. Comparison of English and American processes

GAS ENGINES

See BLOWING ENGINES, Gas-Driven.

GAS MANUFACTURE

Low-Temperature Carbonization. Low Temperature Carbonization of Coal, Steward J. Lloyd. Am. Gas Jl., vol. 114, no. 17, April 23, 1921, pp. 353–354 and pp. 363–364. Survey of recent developments.

Elliott Gas. Elliott Gas, a Substitute for Natural Gas, F. J. Denk. Forging & Heat Treating, vol. 7, no. 4, April 1921, pp. 208–212, 5 figs. Process of manufacturing combination coal and water gas from bituminous coal.

GASES

Dust Precipitators. A New Electrical Precipitation Treater, Motoji Shibusawa and Jasujiro Niwa. Researches of Electrotechnical Laboratory, no. 82, Feb. 1921, 31 pp., 35 figs. Cottrell precipitator with glass-covered electrode.

GASOLINE ENGINES

Fuel Economizer. Fuel Economizer for Petrol Engines. Engineering, vol. 111, no. 2889, May 13, 1921, p. 585, 10 figs. Apparatus for reducing fuel consumption of gasoline engines which are operated for a great part of the time at less than full load It consists of heating chamber to bring about better vaporization of fuel and air valve to dilute mixture with heated air under all conditions of partial load. Manufactured by Lancashire Ordnance Accessories Co., Stockport, England.

GEARS

Helical. New Sykes Double Helical Gear Generator. Machy. (Lond.), vol. 18, no. 450, May 12, 1921, pp. 187–190, 4 figs. Application of pinion type of generating cutter.

The Sykes Double Helical Gear Generator. Engineering, vol. 111, no. 2887, April 29, 1921, pp. 520–522, 7 figs. Cutters are retained in gearing contact with wheel being cut and rotate during process of generation. Machine manufactured by Power Plant Co., West Drayton, England.

Involute. The Evolution of the Involute Gear Tooth —IV, A. Fisher, Machy. (Lond.), vol. 18, no. 447, April 21, 1921, pp. 70–72, 1 fig. Limitations necessitated partly by requirements of interchangeability and partly by solidity of metal.

Maag. The Maag System of Gearing—II. Engr., vol. 131, no. 3407, April 15, 1921, pp. 403–404, 2 figs. Teeth of each wheel are formed on pitch circle of diminished diameter at pressure angle of 15 deg. Thereafter teeth are pushed out radially at proportionate rates until teeth of one wheel touch teeth of other at point dividing line joining shaft centers in desired gear ratio.

Quantity Production. Quantity Production in a Gear Shop—II, Fred R. Daniels. Machy. (N.Y.), vol. 27, no. 9, May 1921, pp. 863–867, 9 figs. Practice of Dittmer Gear & Mfg. Corp., Lockport, N. Y., in manufacture of gears for tractors, trucks, and automobiles.

Spur. Formulae for Measuring Spur Gears by the Pin Method, M. D. Wilson, Mach. (Lond.), vol. 18, no. 447, April 21, 1921, pp. 92–94, 4 figs.

The Shape of Spur-Wheel Teeth for Maximum Life (Die Zahnform des Stirnrades mit längster Lebensdauer), Eugen Stübler. Betrieb, vol. 3, no. 14, Apr. 10, 1921, pp. 414–420, 9 figs. Writer describes and recommends the more accurate tooth flanks. Comparison of the trochoidal and cycloidal types of toothed gearing.

GRAIN ELEVATORS

Floating. Floating Pneumatic Grain Discharging Plant. Engr., vol. 131 no. 3406, April 8, 1921, pp. 378 and 381–384, 9 figs. Combination of pneumatic and band systems for simultaneously discharging from grain ship to lighters by spouts or by means of band conveyor across deck of ship to bands below quay. Capacity is 180 tons per hour. Plant is carried on reinforced-concrete pontoon.

GRINDING

Fixtures. The Use of Special Fixtures in Grinding Operations, Ellsworth Sheldon. Am. Mach., vol. 54, no. 17, April 28, 1921, pp. 736–739, 10 figs. Cylindrical work ground on dead centers. Special holding devices for grinding chuck shells. Magnetic chucks provided with holding strips and aligning bars.

Railway Shops. Economical Grinding Operations Reduce Repair Costs, Herbert R. Simonds. Abrasive Industry, vol. 2, no. 5, May 1921, pp. 153–159, 12 figs. Repair operations at Billerica, Mass., shops of Boston & Main Railroad.

Surface Grinding. Surface Grinding 700 Ball Races Every Hour, J. H. Moore. Can. Machy., vol. 25, no. 18, May 5, 1921, pp. 65–71, 24 figs. Relation of magnetic chucks to surface grinding. Methods of grinding steel forgings, gear blanks, cylinder castings, locomotive-crankpin washers, dies, push rods and connecting rods.

GRINDING MACHINES

British Types. Substantial Design Characterizes British Grinding Machines. Abrasive Industry, vol. 2, no. 5, May 1921, pp. 174–177, 8 figs. Typical British types.

GUN METAL

Specifications. Notes on Gun-Metal, R. T. Rolfe. Metal Industry, (Lond.), vol. 18, no. 14, April 8, 1921, pp. 265–268. Comparison of British Admiralty and British Air Board specifications.

H

HANDLING MATERIALS

Factories. How Materials Are Handled at the Buda Plant, S. Gordon Hyde. Material Handling Mag., vol. 2, no. 1, Mar. 1921, pp. 10–13, 7 figs. Material-handling methods of Buda Co., Harvey, Ill., manufacturers of heavy-duty four-cylinder gasoline engines, electrical industrial trucks and tractors for factory use, railroad gasoline motor cars, etc.

Purchasing and Handling Material in a Moderate Sized Factory—I, Guy V. Sweet. Indus. Manage.

ment, vol. 41, no. 9, May 1, 1921, pp. 335–337, 5 figs. Forms for keeping records of moving material.

Foundries. Handling 168 Tons for Every Ton Produced, Max Sklovsky. Material Handling Mag., vol. 2, no. 1, Mar. 1921, pp. 5–7, 1 fig. Analysis of material-handling system of modern foundry.

Steel Products. Efficient Handling and Trucking of Steel Products, E. C. Phillips. Iron Age, vol. 107, no. 20, May 19, 1921, pp. 1294–1295. Devices speed loading and unloading of motor trucks.

HANGARS

Design. Airship Sheds and Their Erection. Flight, vol. 13, no. 15, April 14, 1921, pp. 263–264, 1 fig. Types of hangar built in Germany during war.

The Great German Dirigible Centers (Les grands centres allemands de dirigeables), J. Sabatier. Aéronautique, vol. 3, no. 22, Mar. 1921, pp. 108–112, 6 figs. Typical designs of hangar and equipment used, notably underground installation of hydrogen tanks.

HEATING

Buildings. Warming Buildings with Refrigerating Equipment, Robertson Matthews. Power, vol. 53, no. 16, April 19, 1921, pp. 628–631, 3 figs. Theoretical study of utilization of low-temperature heat from atmosphere.

Technique. Recent Progress in the Industrial Heating Technique (La technique du chauffage industriel et son enseignement ses bases essentielles et ses progrès récents), Emilo Damour. Chimie & Industrie, vol. 5, no. 3, Mar. 1921, pp. 271–280, 2 figs. Compilation of suggestions in regard to economical utilization of fuel. Prepared under auspices of Central Bureau of Economical Heating, operated under joint control of French Ministries of Industrial Reconstruction and of Labor.

HEATING, ELECTRIC

Industrial. Industrial Electric Heating, A. E. Holloway and H. L. Garbutt. Jl. Electricity & Western Industry, vol. 46, no. 10, May 15, 1921, pp. 486–488 and 517–519, 4 figs. Report of Committee on Industrial Heating to Pacific Coast Section of National Electric Light Association.

HEATING, HOUSE

"Colec" System. The "Colec" System of Central and Radiant Heating, Herbert H. Berry. Elecn., vol. 86, no. 2238, April 8, 1921, pp. 419–420. Combination of coal and electricity for heating houses.

HEATING, STEAM

Central Stations. Load Dispatching in a Central Heating System, J. C. Butler. Power, vol. 53, no. 17, April 26, 1921, pp. 648–651, 7 figs. Meter board in chief engineer's office of Illinois Maintenance Co., Chicago. Flow of steam is measured and recorded.

Return Pipes, Proportions of. The Proportioning of Return Pipes in Steam Heating Installations (Die Bemessung der Kondensleitungen bei Dampfheizungen), O. Liersch. Gesundheits-Ingenieur, vol. 44, no. 7, Feb. 12, 1921, pp. 70–72, 2 figs. Investigation of the field of limitations of the usually employed rules for return pipes. Desiderata for the selection of suitable diameter, the calculation of which, especially for dry returns, is said to be impossible.

HELICOPTERS

Design. The Actual State of the Helicopter Problem, Dr. G. DeBothezat. Aerial Age, vol. 13, no. 11, May 23, 1921, pp. 247–249, 3 figs. Theory of blade-screw action, with notes on problem of descent when motor is stopped.

Karman-Petroczy. Tests Made with Captive Helicopters, Prof. Karman. Flight, vol. 13, no. 18, May 5, 1921, pp. 307–309, 4 figs. Machine consists of three-armed frame made of steel tubes, in which three LeRhone engines are built. Two wooden propellers, each 6 m. in diameter, rotate in opposite directions at about 600 r.p.m.

The Karman-Petroczy Helicopter. Aeronautics, vol. 20, no. 395, May 12, 1921, pp. 342, 2 figs. Three-armed frame made of steel tubes, in which three Le Rhone of 120 hp. each, are mounted. Engines drive two 20-ft. propellers revolving in opposite directions at about 600 r.p.m. Record of lift and stability tests.

Oehmichen-Peugeot. The Oehmichen-Peugeot Helicopter. Engr., vol. 131, no. 3407, April 15, 1921, pp. 411–412, 2 figs. Sustentation is partially derived from hydrogen-filled ballonet. Motor develops 25 hp. Two 2 bladed propellers of 21 ft. diameter rotate in same horizontal plane. Translated from Génie Civil.

Passàt. A New Helicopter. Aeronautics, vol. 20, no. 391, April 14, 1921, p. 253, 1 fig. Passat machine designed to give vertical lift by wing-flapping motion.

Pescara. Testing of Helicopters (Sur les résultats des essais récents d'un hélicoptère), M. Pescara. Comptes rendus des Séances de l'Académie des Sciences, vol. 172, no. 14, April 4, 1921, pp. 845–848, 1 fig. Pescara helicopter. There are two 6.40 meter six-bladed propellers rotating in opposite directions around same vertical axis. Motor is 60 hp. Hispano-Suiza.

The Pescara Helicopter. Aviation, vol. 10, no. 17, April 25, 1921, p. 531, 1 fig. Machine is fitted with two co-axial, six-bladed propellers of 20-ft. diameter. Propellers rotate in opposite directions.

Theory. The Helicopter. H. M. A. S. Riach. Aeronautics, vol. 20, no. 392, April 21, 1921, pp. 280–282, 11 figs. Study of forces produced in helicopter when it has motion of translation as well as motion of ascent vertically.

HOISTING MACHINERY

Design. The Calculation of Hoisting-Machine Elements (Die Berechnung einiger Hebezeuge), Adolf Fleck. Der praktische Maschinen-Konstrukteur, vol. 54, no. 17, Apr. 28, 1921, pp. 129–136, 14 figs. Gives examples of calculations of the most important elements and drives, including hand, electric and hydraulic.

HOISTS

Mine. A Giant Among Mine Hoists. Sci. Am., vol. 124, no. 20, May 14, 1921, p. 381, 1 fig. Mine hoist installed in Lake Superior copper district, Load of 20,000 lb. is raised per trip.

Alden Coal Co. Installs Large Hoist Which Brakes itself If Anything Goes Wrong, Lewis W. LeGrand. Coal Age, vol. 19, no. 18, May 5, 1921 pp. 797–798, 1 fig. Cylindro-conical electrically-driven back-geared 400-hp. platform cage hoist installed in shaft of Alden Coal Co., Alden, Pa.

HOUSING

Europe. Notes on the Housing Situation in Northern Europe. Monthly Labor Rev., vol., 12, no. 4, April 1921, pp. 127–133. Survey of laws passed to relieve emergency and of measures taken to stimulate building of houses.

Industrial. Erecting Houses on Quantity Production Basis. Contract Rec., vol. 35, no. 17, April 27, 1921, pp. 407–409, 10 figs. Typical examples of industrial homes at Walkerville, Ont. Contractor's methods ensure completion of job in 150 working days.

Industrial Housing, Leslie H. Allen. Textile World, vol. 49, no. 18, April 30, 1921, pp. 119–123. Arguments for and against company housing.

HYDRAULIC TURBINES

High-Speed. High-Speed Water Turbines (Schnelllaufende Wasserturbinen), Fr. Oesterlen. Zeit. des Vereines deutscher Ingenieure, vol. 65, no. 16, Apr. 16, 1921, pp. 409–414, 14 figs. Notes on development of high speed and rotor construction up to 1913; braking tests with a very high-speed turbine by Kaplan in 1913; latest development of the Francis high speed and Kaplan turbines up to rotor with only two rotatable blades; the new Kaplan draft-tube system; draft-tube construction and high-speed rotors in America.

Reaction. Maximum Efficiency of Reaction Turbines (Sur le maximum de rendement des turbines à libre déviation), M. deSparre. Comptes rendus des Séances de l' Académie des Sciences, vol. 172, no. 15, April 11, 1921, pp. 896–899. Theoretical study.

Turgo. The Turgo Impulse Water Turbine. Engr. vol. 131, No. 3407, April 15, 1921, pp. 411, 3 figs. Turgo runner of given dimensions is claimed to have 4 to 5 times capacity of runner of Pelton type of similar dimensions.

HYDROELECTRIC PLANTS

Canada. Canada Shows Rapid Hydro Development, J. B. Challis. Elec. World, vol. 77, no. 17, April 23, 1921, pp. 930–934, 9 figs. Work completed or under way during 1920 totals 650,000 hp. Total developments of Dominion now stand at 2,460,000 hp. Ontario shows greatest progress.

Nipigon Power Development of Ontario Hydro Commission, T. C. James. Elec. News, vol. 30, no. 8, Apr. 15, 1921, pp. 30–37, 20 figs. also in Contract Rec., vol. 35, no. 16, April 20, 1921, pp. 389–395, figs. 71. Twenty-five thousand horsepower now available to be increased to three times that amount as demand develops. Transmission at 110,000 volts.

Denmark. Hydroelectric Power Station in Denmark (Gudenaa-Centralens Indvielse), J. P. Schmidt. Ingeniören, vol. 30, no. 6, Jan. 19, 1921, pp. 29–30. Harnessing the Gudenaa River was commenced in 1918 by construction of dam half a mile long across river valley in order to form a storage reservoir of 1640 acres. Water emerges from reservoir through a 1000-ft. channel to power station with fall of 33 ft. Three duplex turbines are direct coupled to 1500 kw generators, producing current at 10,000 volts. Total output of 10,000,000 kw-hr. will be obtained annually.

Economics. Economics of Hydro-Electric Development, A. H. Gibson. Engr., vol. 131, nos. 3406–3407, April 8 and 15, 1921, pp. 367–369, 3 figs. and 393–394. Apr. 8: Derivation of formulas from general economic considerations and records of actual cases. Apr. 15. Examination of typical Canadian, American and European installations indicates that total annual costs, excluding transmission and taking 6 per cent as rate of interest on capital, amount very nearly to 9.5 per cent of capital cost.

Efficiency. Increasing the Efficiency of Water-Power Plants, Charles M. Allen. Power, vol. 53, no. 19, May 10, 1921, pp. 761–762, 2 figs. Speed-horse-power curves for various heads. Paper read before Technical Assn. of Pulp and Paper Industry.

Mt. Rainier National Park. Power Generation in Mt. Rainier National Park, C. P. Gordon. Jl. Electricity & Western Industry, vol. 46, no. 9, May 1, 1921, pp. 436–437, 3 figs. Installation for generation of 400 kw. at 2300 volts.

Norway. The Hydroelectric Plants on the Rjukanfos Waterfalls in Norway (Die Wasserkraftwerke am Rjukanfos und am Glomfjord in Norwegen), Gg. v. Troeltsch. Zeit. des Vereines deutscher Ingenieure, vol. 65, no. 13, Mar. 26, 1921, pp. 309–314, 8 figs. Notes on the two water-power stations located one directly beneath the other on Norway's most famous waterfall. Details of water inlet from upper to lower plant with 250 m. head; interesting features of the speed and pressure governors of the main turbines of lower station which have output of 16,400 hp. each; upper auxiliary turbine of 7000 hp. with 168 m. head, and use of water for supply of nitrogen factory; lower auxiliary turbines with same output and 250 m. head; interdependence of the two auxiliary turbines, regulation, etc.

Operation. Operation for Maximum Output, and Operating Records, Geo. H. Bragg. Jl. of Electricity & Western Industry, vol. 46, no. 10, May 15, 1921, pp. 504–508, 5 figs. Investigation of a number of western hydrolectric systems. Report of Sub-Committee of the Hydraulic Committee to Pacific Coast Section of National Electric Light Association.

Reservoirs. Importance of Reservoirs and Artificial Lakes in the Production and Distribution of Electrical Energy (Importanza dei serbatoi e dei laghi artificiali nella produzione e distribuzione dell'energia elettrica), Angelo Forti. Giornale del Genio Civile, vol. 59, Feb. 28, 1921, pp. 77–87, 8 figs. Economical study.

I

IMPACT TESTING

Machines. Apparatus for the Measurement of Impact (Apparat zum Messen von Stössen), H. Kreuger. Bauingenieur, vol. 2, no. 4, Feb. 28, 1921, pp. 103–106, 7 figs. Describes apparatus successfully used by author with good results for measuring effects of impact of falling weights and blasting agents against concrete and against other materials and structures under widely different conditions.

INDICATORS

Internal-Combustion-Engine. A New Type of Indicator for High-Speed Internal-Combustion Engines, Augustus Trowbridge. Power, vol. 53, no. 18, May 3, 1921, pp. 704–708, 16 figs. Diagram, electrically transmitted, shows velocity of cylinder pressure changes at every instant instead of actual pressures. Usual form for ascertaining power consumption may be constructed mathematically from it.

INDUSTRIAL CONDITIONS

Europe. Our National Industries and International Business, Dwight T. Farnham. Indus. Management vol. 41, no. 9, May 1, 1921, pp. 331–334. Altered European industrial conditions and their effect on American employer and employee.

INDUSTRIAL MANAGEMENT

Inspection. Principles of Inspection, Louis Ruthenburg and R. A. Crist. Machy. (N. Y.), vol. 27, no. 9, May 1921, pp. 859–862. Review of principles upon which rational inspection methods are based, with special application to interchangeable manufacture.

Putting Inspection Where It Belongs, F. R. Schubert. Factory vol. 26, no. 9, May 1, 1921, pp. 1062–1064, 4 figs. Advises keeping inspection distinct from supervision.

The Organization of the Inspection Department, George S. Radford. Indus. Management, vol. 41, no. 9, May 1, 1921, pp. 356–360, 1 fig. Suggests organization plan for inspection force.

International Organization. Building an International Business Organization, George M. Gales. Indus. Management, vol. 41, no. 9, May 1, 1921, pp. 319–323. Writer's experience in organizing Liggett's International Ltd. Notes on Brittish personnel and English business attitude toward America.

Machine Cards. Alphabetical and Memonic Symbols on Tabulating Machine Cards, C. Moffitt Ford. Indus. Management, vol. 41, no. 9, May 1, 1921, pp. 347–350, 2 figs. Methods for expressing alphabetical, semi-alphabetical and memonic symbols on tabulating machine cards.

Production Systems. Controlling Production. Eng. Production, vol. 2, no. 30, April 28, 1921, pp. 534–537, 4 figs. System of handling components in batches.

Routing Materials. System for Production Control. Machy. (Lond.), vol. 18, no. 450, May 12, 1921, pp. 179–181, 8 figs. Methods employed in plant of American Multigraph Co. for routing and recording progress of work.

Shop Analysis. The Zoning of Jobs, Hugh L. Clary. Indus. Management, vol. 41, no. 9, May 1, 1921, pp. 329–334, 4 figs. Suggests plans for analyzing certain classes of positions as to requirements for compensation.

INDUSTRIAL TRUCKS

Electric. Electric Trucks and Industrial Locomotives—V-VIII. Engr., vol. 131, nos. 3406–9, April 8, 15, 22 and 29, 1921, pp. 374–376, 10 figs., 402–403, 8 figs., 424–426, 8 figs., and 456–458, 8 figs. Typical British designs.

INSULATING MATERIALS

Research. Industrial Research Work on Insulating Materials. Engineering, vol. 111, no. 2886, April 22, 1921, pp. 482–484, 6 figs. Account of work undertaken by Research Committee of Vickers, Ltd., England.

INTERNAL-COMBUSTION ENGINES

Induction Pipes. Induction and Exhaust Pipes. Automobile Engr., vol. 11, no. 149, April 1921, pps 150–152, 18 figs. Résumé of some recent experiment. in Germany.

Silencers. Silencers for Internal-Combustion Marine Engines, Engineering, vol. 111, no. 2881, April 8, 1921, p. 422, 4 figs. Mechanism in which energy of exhaust gases is employed to put in motion comparatively large body of cooling water or air.

"Silent Record." "Silent Record" Internal-Combustion Engine. Engineering, vol. 111, no. 2888, May 6, 1921, p. 565, 2 figs. Engine constructed by Record Engineering Co., Burton-on-Trent, England. Engine has four cylinders and two cranks, each pair

of cylinders having common head and valve mixer and being fed with same charge.

[See also AEROPLANE ENGINES; AUTOMOBILE ENGINES; DIESEL ENGINES; GAS ENGINES; GASOLINE ENGINES; INDICATORS; OIL ENGINES.]

IRON

Electrodeposited. "Slip-Lines" and Twinning in Electro-Deposited Iron, W. E. Hughes. Engineering, vol. 111, no. 2889, May 13, 1921, p. 583, 10 figs. partly on suppl. plate. Photomicrographs showing various samples of electrodeposited iron. (Abstract). Paper read before Iron and Steel Inst.

Thermal Analysis. Analysis of Transformations Occurring in Quartz, Iron and Nickel Under Action of Heat (Sur une methode sensible d'analyse thermique et les transformations du quartz, du fer et du nickel), Albert Perrier and F. Wolfers. Revue de Métallurgie, vol. 18, no. 2, Feb. 1921, pp. 111–116, 4 figs. Results of experiments.

J

JIGS

Design. Tool Engineering, Albert A. Dowd and Frank W. Curtis. Am. Mach., vol. 54, nos. 17, 18 and 19, April 28, May 5 and 12, 1921, pp. 720–725, 12 figs. 770–772, 9 figs. and 816–819, 14 figs. Effect of design on manufacture. Consideration of limits of accuracy. Selection of working points. Relation of design to cost of machining. Drill-jig design. Location of rough and finished work. Correct and incorrect location and clamping. Types of jigs.

L

LABOR

Railroad Labor Board. Principles to Govern Agreements Defined by Labor Board. Ry. Mech. Engr., vol. 95, no. 5, May 1921, pp. 287–289. Text of board's decision on national agreements.

LABOR TURNOVER

Records. The analysis of Labor Records, David R. Craig. Indus. Management, vol. 41, no. 9, May 1, 1921, pp. 374–376, 1 fig. Chart for visualizing variables entering into labor turnover.

Reduction. Reducing Foreign Labor Turnover, Arthur Hanko. Indus. Management, vol. 41, no. 9, May 1, 1921, pp. 367–369, 4 figs. Writer's experience in handling foreign workers.

LATHES

Bench. Tools and Methods for Manufacturing Precision Bench Lathes. Machy. (Lond.), vol. 18, nos. 446, 448 and 450, April 14, 28 and May 12, 1921, pp. 33–37, 8 figs., 108–111, 10 figs., and 165–168, 7 figs. Processes used in manufacture of precision bench lathes. Practice in Manufacture of Potter bench lathes. Machining and inspection methods of Toolmakers & Light Machinery, Ltd., England.

Screw-Cutting. Cutting Threads on the Screw-Cutting Lathe (Gewindeschneiden auf der Leitspindeldrehbank), Gustaf Fäldt. Werkstattstechnik, vol. 15, nos. 6 and 7, Mar. 15 and April 1, 1921, pp. 151–155 and 182–188, 64 figs. Deals with shape, operation, position and manipulation of chasers and auxiliary tools, such as gages, supports and grinding devices.

Taper Turning. Taper Turning on Automatic Lathes by use of Concentrically Turned Cams (Kegeldrehen auf selbsttätigen Drehbanken mittels zentrisch gedrehter Vorhaltkurve), Hermann Zimmermann and Max Diener. Werkstattstechnik, vol. 15, no. 7, Apr. 1, 1921, pp. 181–182, 3 figs. Describes device for producing a sufficiently accurate taper.

LAUNCHING

Sideways. Freyssinet Process of Launching Reinforced Concrete Barges Sideways (Transportet lancet ment par le travers de coques de 1000 tonnes suivant les procédés Freyssinet), H. deLauriston. Génie Civil, vol. 78, no. 17, April 23, 1921, pp. 345–350, 8 figs.

LIFTING MAGNETS

Development and Uses. Construction of Lifting Magnets (Der Stand des Lastmagnetbaues), H. Wintermeyer. Elektrotechnischer Anzeiger, vol. 38, nos. 45–46 and 47, Mar. 23 and 24, 1921, pp. 263–265 and 273–274, 8 figs. Notes on present status of development and uses, especially in iron foundries.

Types. Electric Lifting Magnets. Eng. Production, vol. 2, no. 28, April 14, 1921, pp. 472–474, 3 figs. Typical designs. Paper read before Staffordshire Iron & Steel Inst.

LIGHTING

Industrial. The Safety Features of Industrial Lighting, Samuel G. Hibben. Trans. Illuminating Eng. Soc., vol. 16, no. 3, April 30, 1921, pp. 47–55, 12 figs. Relation between light speed and safety in industrial operations.

Technique. Illuminating Engineering and Engineers (Ueber Lichttechnik und Lichttechniker), J. Teichmüller. Zeit. des Vereines deutscher Ingenieure, vol. 65, no. 17, Apr. 23, 1921, pp. 435–440. Discussion of what is good illumination and for and with whom the illuminating engineer has to work. Natural and artificial light and lighting. Methods of calculating illumination of open and closed spaces; street lighting, etc. Faults in lighting plant. Schools, research institutes and technical associations for promotion of illuminating technique.

LIGNITE

Briquetting. Manufacturing of Briquets from Lignite. (Die Brikettierung der Braunkohle), H. Landsberg. Zeit. des Vereines deutscher Ingenieure, vol. 65, no. 16, Apr. 16, 1921, pp. 415–417, 1 fig. Relations between raw coal and briquets with regard to quantity and heating value, and the power and heat requirements in the manufacture of briquets are derived in a general way and presented with respect to the water volume to be evaporated.

North Dakota. The New Salem Lignite Field, Morton County, North Dakota, Eugene T. Hancock. U. S. Dept. of Interior, U. S. Geological Survey, no. 726–A, May 6, 1921, 39 pp., 9 figs. Fuel is of very low grade. Notes on its utilization.

Utilization. American Lignite Coals, Robert G. Skerrett. Sci. Am., vol. 134, no. 18, April 30, 1921, pp. 344 and 355, 1 fig. Carbonizing and briquetting plant under construction at Bienfait, Saskatchewan.

LOCOMOTIVE BOILERS

Tubes. Notes on Fractures in Locomotive Boiler Tubes, Henry Fowler. Engineering, vol. 121, no. 2885, April 15, 1921, pp. 466–467, 11 figs. Analyses of superheater flue tubes taken out of engine of Midland Ry. locomotive which had run 60,000 miles. Photomicrographs. Paper read before Faraday Soc.

LOCOMOTIVES

Automatic Control of Cut-Off. Automatic Operation of Reverse Lever Accomplished, E. S. Pearce. Ry. Rev. vol. 68, no. 21, May 21, 1921, pp. 763–770, 13 figs. Apparatus consists of two differential valves set at a difference of 1 lb. per sq. in., one shortening cut-off when back pressure increases and the other lengthening cut-off when back pressure decreases.

British. British Locomotives in 1920, J. F. Gairns. Bul. Int. Ry. Assn., vol. 3, no. 4, April 1921, pp. 409–418, 6 figs. Characteristics of leading designs.

Locomotive Building in an English Shop, I. Wm. Chubb. Am. Mach., vol. 54, no. 17, April 28, 1921, pp. 713–719, 19 figs. Manufacturing processes at plant of Armstrong, Whitworth & Co.

New 4–6–4 Type Tank Locomotive, Furness Railway. Ry. Gaz., vol. 34, no. 14, April 8, 1921, pp. 538–539, 3 figs. Characteristics: Total wheel base of engine, 40 ft. 9 in.; diameter of coupled wheels, 5 ft. 8 in.; total length of frame, 45 ft. 9 in.; length of firebox, 8 ft. 6 in.

Connecting Rods. Machining Operations on Locomotive Connecting Rods, Frank A. Stanley. Am. Mach., vol. 54, no. 19, May 12, 1921, pp. 811–813, 12 figs. Practice in shops of Southern Pacific Co. at Sacramento, Cal.

Consolidation. Consolidation Locomotives for the Western Maryland. Ry. Age, vol. 70, no. 19, May 13, 1921, pp. 1117–1120, 8 figs. Comparison of recent designs of Consolidation types.

Most Powerful Consolidation Locomotive Ever Built. Ry. Rev., vol. 68, no. 20, May 14, 1921, pp. 735–737, 1 fig. Characteristics: Tractive effort, 68,200 lb.; cylinders, 27 in. by 32 in.; diameter of drivers, 61 in.; weight on drivers, 268,200 lb.; weight of locomotive, 294,900 lb.; weight of locomotive and tender, 565,000 lb.

Continuous Draft. Continuous Draft in Locomotives (Le tirage continu dans les locomotives), H. Daubois. Arts et Métiers, no. 3, Dec. 1920, pp. 55–57, 2 figs. Disadvantages of pulsating draft produced by exhaust-steam locomotives. Device for rendering draft continuous.

Design. Features of Locomotive Design Affecting Wear on Track. Ry Rev., vol. 68, no. 20, May 14, 1921, pp. 737–739, 4 figs. Paper read before Moncton Branch, Eng. Inst. Canada.

Some Features of the Design of Locomotives Introduced for the Purpose of Modifying Their Effect on the Track, Frank Williams. Jl. Eng. Inst. of Canada, vol. 4, no. 5, May 1921, pp. 309–311, 4 figs. Effect of static load, dynamic augment, impact, lateral flange thrust and abrasion on locomotive design.

The Design of Large Locomotives, M. H. Haig. Mech. Eng., vol. 43, no. 5, May 1921, pp. 311–314, and 326, 6 figs. Features which keep engine in service maximum length of time, reduce maintenance and repair costs, and increase revenue-earning power.

Injectors. The Advantages of the Exhaust Steam Injector, Clarence Roberts. Ry. Mech. Engr., vol. 95, no. 5, May 1921, pp. 290–291, 3 figs. Experience of French and English railways in use of exhaust-steam injector.

Mine. Experience Results in Radical Changes in Mine Locomotives for Heavy Duty, B. S. Beach. Coal Age, vol. 19, no. 18, May 5, 1921, pp. 792–795, 4 figs. Leaf springs and equalizing-bar suspensions make derailments less frequent. Frames cut from steel plate resist inevitable violence in operation. Tandem operation makes bigger trips possible. Electric brakes prevent runaways.

Power Reverse Gear. Tests Demonstrate Precision of New Power Reverse Gear. Ry. Rev., vol. 68, no. 18, April 30, 1921, pp. 668–670, 2 figs. Gear developed by Franklin Ry. Supply Co.

Tests of Franklin Precision Power Reverse Gear. Ry. Age, vol. 70, no. 17, April 29, 1921, pp. 1043–1044 2 figs. Gear consists of 10 in. by 18 in. cylinder with all parts enclosed. Operating valve is attached to rear end of cylinder and is controlled by hand wheel in cab. This wheel is provided with indicator showing point of cut-off and is connected to gear by operating rod.

Production Methods. Automatic Production Methods in a Locomotive Works. Eng. Production, vol. 2, no. 30, April 28, 1921, pp. 545–550, 15 figs. Methods and tools employed at works at Lancashire & Yorkshire Ry. Co., England.

Reconstruction. Converted Express Locomotives, Lancashire & Yorkshire Railway. Ry. Gaz., vol. 34, no. 15, April 15, 1921, pp. 580–581, 2 figs. Four-cylinder 4–6–0 type engines being converted to superheated steam with larger cylinders, redistribution of weight and other modifications tending to increase their tractive effort and general utility.

Superheater. Modern Express Locomotives, M. Igel, Eng. Progress, vol. 2, no. 3, Mar. 1921, pp. 49–54. 10 figs. German superheating locomotives.

Valve Gears. Railway Machine Shop Practice—II, Edward K. Hammond. Machy. (N. Y.), vol. 27, no. 9, May 1921, pp. 855–858, 8 figs. Methods of machining parts of locomotive valve gears, valves and pistons.

LUBRICANTS

Mineral. The Production of Mineral Lubricants. J. E. Pogue. Sci. Lubrication, vol. 1, no. 3, Mar. 1921, pp. 6–11. Statistics concerning use of petroleum lubricants in U. S.

M

MACHINE SHOPS

Layout. A Modern Tractor Building Machine Shop, J. V. Hunter. Am. Mach., vol. 54, no. 19, May 12, 1921, pp. 804–807. General layout of tools and equipment. Arrangements on cranes and conveyors. Heating and lighting systems.

MACHINE TOOLS

Semi-Automatic. Semi-Automatic Machines for Repetition Precision and Instrument Work—I. Machy. (Lond.), vol. 18, no. 446, April 14, 1921, pp. 49–51, 5 figs. Machine Tools manufactured by Mikron firm of Bienne-Madretsch, Switzerland.

MACHINERY

Depreciation. A Method for the Depreciation of Machinery, H. C. Marris. Eng. & Indus. Management, vol. 5, no. 15, April 14, 1921, p. 426, 1 fig. Method of determining depreciation of machinery. Graph illustrating differences between method of depreciation on logarithmic basis and method of equal annual fractions.

Noise Examination. The Examination of Noise in Mechanisms. Automobile Engr., vol. 11, no. 149, April 1921, pp. 148–149, 6 figs. Dual valve tectoscope for detecting a locating sound.

Vibrations. Eliminating Vibration, an Enemy of Production, Charles L. Hubbard. Factory, vol. 26, no. 9, May 1, 1921, pp. 1075–1078, 10 figs. Methods of insulating against foundation vibration.

MACHINING METHODS

Navy Yard. Large Machine Work at the Puget Sound Navy Yard, Fred H. Colvin. Am. Mach., vol. 54, no. 19, May 12, 1921, pp. 801–803, 9 figs. Machining Operations.

Pump Bodies. Machining Cast Iron Pump Body in 22 Minutes, A. H. Lloyd. Can. Machy., vol. 25, no. 17, April 28, 1921, pp. 32–34, 6 figs. Special chuck jaws are used and taper bore is produced by profile method.

Repetition Work. Interesting Operations on Repetition Work. Eng. Production, vol. 2, no. 29, April 21, 1921, pp. 513–518, 14 figs. Examples of works practice of Messrs. George Kent, England.

Swiveling Slide. Machining a Swiveling Slide. Eng. Production, vol. 2, no. 28, April 14, 1921, pp. 490–491, 5 figs. Notes on methods and tools employed.

MALLEABLE IRON

Casting. Malleable Iron (La fonte malléable), Christian Kluytmans. Fonderie Moderne, no. 3, Mar. 1921, pp. 49–54, 7 figs. European process of casting malleable iron.

Melting. American Malleable Cast Iron—X, H. A. Schwartz. Iron Trade Rev., vol. 68, no. 19, May 12, 1921, pp. 1317–1321, 8 figs. Melting processes.

Foundries. American Malleable Cast Iron—IX, H. A. Schwartz. Iron Trade Rev., vol. 68, no. 17, April 28, 1921, pp. 1175–1180, 7 figs. Notes on organization, layout, labor and equipment of malleable foundry.

MEASUREMENTS

Torque. A Simple Method for Torque Measurement (Ein einfaches Messverfahren Fur Drehmomente), W. Schmidt, Zeit. des Vereines deutscher Ingenieure, vol. 65, no. 17, Apr. 23, 1921, pp. 441–444, 11 figs. Described method tested in experiments with model propellers and shown to be adaptable for the determination of performance of built-in boat engines.

Torsion. A New Electric Torsion Meter (Ein neuer elektrischer Verdrehungsmesser), Gg. Keinath. Dinglers polytechnisches Jl., vol. 335, no. 25, Dec. 11, 1920, pp. 265–268, 6 figs. Describes electric meter in which the relative position of two cross-sections of a shaft under torsion causes the change of air-gap of two choking coils. The relation of the currents indicated in both coils is measured showing that the indication is independent of oscillations of the auxiliary voltage.

METALS

Electrical Conductivity. The Measurement of Electrical Conductivity in Metals and Alloys at High Temperatures, John L. Haughton. Trans. Faraday Soc., vol. 16, no 2, Dec. 1920, pp. 392–401, 6 figs. In investigation of constitution of copper-

aluminum-zinc alloys it was found that liquidus and solidus occur, over short range, so close together that it was not possible to distinguish between them by means of thermal curves. Electrical conductivity measurements showed marked changes in direction of curve connecting conductivity and temperature at both solidus and liquidus.

Failure. The Mechanism of Failure of Metals from Internal Stress, W. H. Hatfield. Engineering, vol. 111, no. 2884, April 8, 1921, p. 435. Experiments on wrought iron, brass and silver. It is concluded that, except in certain cases where selective chemical or physico-chemical action causes separation of remains of crystals from each other, fractures are generally due to internal stresses introduced during processes of manufacture. (Abstract.) Paper read before Faraday Soc.

Fatigue. Metal Fatigue Under Repeated Stresses. Jl. Soc. Automotive Engrs., vol 8, no. 5, May 1921, pp. 417–418. Survey of tests by various experimenters. Paper read before Am. Iron & Steel Inst.

Microstructure. Internal Stresses in Relation to Micro-Structure, J. C. W. Humfrey. Engineering, vol. 111, no. 2884, April 8, 1921, pp. 419–420, 2 figs. Study of microstructure of metals and of mechanism of their behavior under plastic deformation. It is suggested that elastic limit be determined by alternating tests rather than by tensile tests. (Abstract.) Paper read before Faraday Soc.

Structure. The Crystalline Structure of Metals, Zay Jeffries and R. S. Archer. Chem. & Metallurgical Eng., vol. 24, no. 18, May 4, 1921, pp. 771–779, 18 figs. Definition of crystallinity. Discussion of methods used in X-ray analysis of atomic spacing and statement of results of such studies made to present time.

METEOROLOGY

Aviation. What the Weather Bureau Does for Air Pilots. Aviation, vol. 10, no. 19, May 9, 1921, pp. 595–597, 1 fig. Upon receipt of telephonic or telegraphic requests giving course of projected flight, Bureau furnishes all information as to fog, smoke, wind, visibility, etc. List of stations to which applications may be addressed.

Weather Control. The Artificial Control of Weather, Napier Shaw. Aeronautics, vol. 20, nos. 391 and 392, April 14 and 21, 1921, pp. 260–261, and 283–284. Also in Aerial Age, vol. 13, no. 9, May 9, pp. 203–205. Methods proposed to British Meteorological Office during war. Dissipation of fog by heat. Lecture before Cambridge Univ. Aeronautical Soc.

METRIC SYSTEM

Arguments Against Adoption in U. S. Why the Metric System Should Not Be Adopted, W. R. Ingalls. Min. & Metallurgy, no. 173, May 1921, pp. 15–16. Reasons against compulsory adoption of metric system in U. S.

Arguments in Favor of Adoption in U. S. Why It Should Be Done the Metric Way, Howard Richards, Jr. Min. & Metallurgy, no. 173, May 1921, pp. 13–14. Advantages of system. Reasons why it should be adopted in U. S.

Compulsory Adoption in U. S. Another Thoroughly Vicious Compulsory Metric Bill is Introduced. Am. Mach., vol. 54, no. 18, May 5, 1921, pp. 800c–800d. Bill introduced in House of Representatives on April 11, 1921 "to fix the metric system of weights and measures as the single standard of weights and measures for certain uses."

South America. Are the South American Countries Metric? C. C. Stutz. Machy. (N. Y.), vol. 27, no. 9, May 1921, pp. 871–872. Confusion due to double and in many cases triple standard of weights and measures.

MILLING

Fixtures. Milling Square-Stem Pinions, Machy. (N. Y.), vol. 27, no. 9, May 1921, pp. 849–851, 4 figs. Fixtures designed by Brown-Lipe-Chapin Co., Syracuse, N. Y.

Production Systems. Interesting Milling Operations. Eng. Production, vol. 2, no. 28, April 14, 1921, pp. 475–480, 15 figs. Production systems at works of Alfred Herbert, England.

MILLING CUTTERS

Face and Form Mills. Metal Cutting Tools,—IX A. L. DeLeeuw. Am. Mach., vol. 54, nos. 17 and 19' April 28 and May 12, 1921, pp. 732–735, 5 figs.,' and 807–810, 13 figs. April 28: Types of face-mills. May 12: Principle of construction of form mill.

MILLING MACHINES

Horizontal. Horizontal Milling Machine. Engineering, vol. 111, no. 2886, April 22, 1921, pp. 484–486 5 figs. Heavy constant-speed-drive horizontal milling machines built by Brown & Sharpe Mfg. Co., Providence, R. I.

MINERS' LAMPS

Gauzes. The Relative Safety of Brass, Copper, and Steel Gauzes in Miners' Flame Safety-Lamps, L. C. Ilsley and A. B. Hooker. U. S. Dept. of Interior, Bur. of Mines, no. 228, 1921, 39 pp., 18 figs. Tests. For conditions of high temperature, steel proved superior to either brass or copper; for low temperatures, advantage of steel over brass or copper was little. Brass proved more satisfactory than copper.

MOLDING METHODS

Austrian Foundry. Molding Cylinders in an Austrian Shop, Charles Irresberger. Foundry, vol. 49, no. 10, May 15, 1921, pp. 383–390, 38 figs. Processes at large foundry in Salzburg, Austria.

Propellers. Molding Propellers by Thacher Process, Enrique Touceda. Iron Age, vol. 107, no 20 May 19, 1921, pp. 1310–1312, 4 figs Method calculated to insure accurate product requiring no machining. Blades and wheels of semi-steel. Paper read before Am. Inst. Min. & Metallurgical Engrs.

MONEL METAL

Reflecting Power. Reflecting Power of Monel Metal, Stellite, and Zinc, W. W. Coblentz U. S. Dept. of Cmmerce, Sci. Paper, Bur. of Standards, no. 379, June 10, 1920, pp. 249–252, 1 fig. It was found that in infra-red spectrum reflectivity of monel metal is practically same as that of nickel. Invisible spectrum reflectivity is slightly lower than that of nickel.

MOTION-PICTURE PROJECTION

Substitute for Reel Film. Is the Reel Film the Only Medium for Photographing of Motion Pictures? (Ist das Filmband das einzige Mittel für Verwirklichung des Laufbildesg?) Karl Geutil. Deutsche Optische Wochenschrift, vol. 7, no. 13, Mar. 27, 1921, pp. 215–217, 4 figs. Discusses possibilities of substituting the mutoscope principle of film leaves in combination with the epidiascope in place of the inflammable reel film of celluloid.

MOTOR TRUCKS

Trailers. The Tracking and Steering of Trailers Analyzed by a Graphic Method, Marius C. Krarup. Automotive Industries, vol. 44, nos. 18 and 19, May 5 and 12, 1921, pp. 955–957, 7 figs., and 1008–1011, 4 figs. Engineering investigation of factors bearing upon steering and tracking of various trailer outfits. Free trailing more suitable for short hauling outfits; and steady steering for slow hauling. Graphic method of analysis.

MOTORCYCLES

Performance. Comparative Motorcycle Performance, D. S. Heather. Automobile Eng., vol. 11, no. 150, May 1921, pp. 187–194, 22 figs. Tests for determining effect of road service irregularities of mud, and also to study deceleration resulting from wind resistance.

MOTORSHIPS

Standardization. Motor Shipbuilding. Times Eng. Supp., no. 558, April 1921, p. 125. Extent to which standardization both of machinery and hulls has been adopted.

O

OIL ENGINES

Fuel Injection. Air-Injection or Mechanical-Injection—IV, J. L. Chaloner. Motorship, vol. 6, no. 5, May 1921, p. 399. Comparison from exhaust temperatures record of relative degree of combustion for two systems. (Concluded.)

OIL FIELDS

Montana. Oil Possibilities in Montana, L. S. Ropes. Eng. & Min. Jl., vol. 111, no. 18, April 30, 1921, pp. 754–755. Favorable oil formations noted in searching for coal fields.

Northwestern Canada. The search for Oil in the West. Can. Min. Jl., vol. 42, no. 16, April 22, 1921, p. 313–323, 20 figs. Account of prospecting operations. Notes on geology of region. Paper read before Can. Inst. Min. & Metallurgy.

South America. The Oil Resources of South America, Henry B. Milner. Min. Mag., vol. 24, no. 4, April 1921, pp. 203–210, 1 fig. Republics of Argentine, Ecuador, Columbia and Venezuela are believed to offer substantial opportunities for profitable investigations because they include areas in which both geological and structural conditions are suitable to oil accumulation.

Underground Conditions. Underground Conditions in Oil Fields, A. W. Ambrose. U. S. Dept. of Interior, Bur, of Mines, bulletin 195, 1921, 248 pp., 43 figs. Points out general method of procedure in studying underground conditions in oil fields, and urges coöperation between technical and practical men in application of engineering methods in developments of oil field.

OIL FUEL

Safety Tank. Safety Tank for Storing Inflammable Liquids (Schutzgas Lagerungen feuergefährlicher Flüssigkeiten), H. von Löw. Automobil-Rundschau, vol. 20, no. 5–6, Mar. 1921, pp. 51–53, 5 figs. Details of different arrangements employing a non-inflammable gas under pressure to force out liquid from tank and also to prevent flame or sparks from reaching it.

Specifications. New Fuel Oil Specifications. Oil News, vol. 9, no. 8, April 20, 1921, p. 28. Specifications for various grades used by U. S. Government.

OIL SHALES

Distillation. A Study of the Saturated and Unsaturated Oils from Shale, C. W. Botkin. Chem. & Metallurgical Eng., vol. 24, no. 20, May 18, 1921, pp. 876–880. Investigation of amount and causes of unsaturates in shale oils. Cracking during retorting and distillation accompanied by increase in saturation. Unsaturates vary with nature of shale and methods of pyrolysis.

OIL WELLS

Oil Production. Some principles Governing the Production of Oil Wells, Carl H. Beal and J. O. Lewis. U. S. Dept. of Interior, Bur. of Mines, Bull. 194, 1921, 58 pp., 7 figs. Conditions affecting amount of oil in oil sand. Factors that control rate of production in oil wells. Effect of production of one well on that of another.

OPEN-HEARTH FURNACES

Control Valve. New Oil Fuel Control Valve for Open Hearth Furnaces. Iron Age, vol. 107, no. 18, May 5, 1921, p. 1163. Combination Three-way and proportional discharge valve designed by S. A. Gabriel & Co., Cleveland.

Heat Transfer. Heat Transfer in Open Hearth Furnaces, Henry William Seldon. Blast Furnace & Steel Plant, vol. 9, no. 5, May 1921, pp. 299–304. Survey of experimental studies made by various investigators in different countries.

OXY-ACETYLENE WELDING

Refrigerating Apparatus. Oxy-Acetylene Welding on Refrigerating Apparatus, Fred E. Rogers. Acetylene Jl., vol. 22, no. 11, May 1921, 599–606, 27 figs. Examples illustrating practice. Paper read before Am. Soc. of Refrigerating Engrs.

Tests. An Investigation of Oxy-Acetylene Welding and Cutting Blow-pipes, R. S. Johnston. Mech. Eng., vol. 43, no. 5, May 1921, pp 305–310 and 359, 8 figs. Tests carried out by Bur. of Standards for War Department on commercial apparatus for cutting and welding by oxy-acetylene welding process. Photomicrographs.

[See also AUTOGENOUS WELDING.]

P

PAPER MANUFACTURE

Laboratory Tests. An Outline of Laboratory Tests Used in Pulp aud Paper Making, A. Le Chatelier. Paper, vol. 28, no. 8, April 27, 1921, pp. 17–21. Translated from Chimie et Industrie.

PARACHUTES

German Types. Tests on New Types of Parachute. Aeronautics, vol. 20, no. 392, April 21, 1921, pp. 277, 1 fig. Parachutes designed with view to lessening shock on opening. Device submitted in contest organized by German Air Sport Committee under auspices of Sci. Soc. for Aeronautics.

PATTERN MAKING

Shop Organization. A Model Pattern Shop and Storage Building, Gilbert L. Lacher. Iron Age, vol. 107, no. 18, May 5, 1921, pp. 1165–1168, 7 figs. Pattern storage of Whiting Corporation, Harvey, Ill.

PEAT

Distillation. The Distillation of Peat and Wood (Die Entgasung von Torf und Holz), B. Waeser. Zeit. für angewandte Chemie, vol. 34, no. 13, Feb. 15, 1921, pp. 51–54, 2 figs. Discussion of different processes and plants.

Utilization. Peat Power Plants in Germany. Engr., vol. 131, no. 3408, April 22, 1921, pp. 422–423, 1 fig. Scheme involving construction of 7 power plants, 5 operated with peat and lignite and 2 hydroelectric plants. Plants are to be interconnected and will deliver power to country at 150,000 volts.

PHOSPHOR BRONZE

Tests. Note on Phosphor Bronze Bars, John Arnott. Engineering, vol. 121, no. 2885, April 15, 1921, pp. 474, 2 figs. Tensile tests. (Abstract.) Paper read before Faraday Soc.

PIG IRON

Foundry. Some Defects in Foundry Pig Irons, Y. A. Dyer. Iron Age, vol. 107, no. 17, April 28, 1921, pp. 1093–1094. Examples of bad effect of iron oxide.

PIPE BENDS

Design. The Design of Pipe Bends for Expansion in Pipe Lines, J. G. Stewart. Power, vol. 53, no. 19, May 10, 1921, pp. 742–743, 4 figs. Chart for computing expansion of U-bends of commercial steel pipe with nominal diameters 2 in.–12 in. inclusive.

PIPE, CAST-IRON

Centrifugal Process. Cast Iron Pipe Made by the de Lavaud Process, Peter Gillespie. Can. Engr., vol. 40, no. 19, May 12, 1921, pp. 454–455, 4 figs. Comparative weights of pipe made by centrifugal process and sand mold pipe.

PIPE, CONCRETE

Pressure. New Type Concrete Pressure Pipe Successful in Severe Test. Concrete Products, vol. 20, no. 4, April 1921, pp. 15–20, 9 figs. Steel cylinder encased in concrete the latter being reinforced by wire mesh or bars on both sides of steel cylinder.

Tests. New Concrete Pressure Pipe Tested. Concrete, vol. 18, no. 5, May 1921, pp. 242–244, 4 figs. Pipe consisting of steel cylinder and lap horizontal joint welded on outside only, the whole being encased in concrete.

PIPING

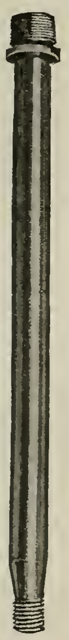
Calculation Chart. A Chart for the Calculation of Steam and Air Piping (Tafel für die Berechnung von Dampf- und Luftleitungen), Alexander Fisher. Zeit. des. Vereines deutscher Ingenieure, vol. 65, no. 18, Apr. 30, 1921, pp. 469–470, 1 fig. Alignment chart is developed which permits a rapid graphic determination of pressure drop, diameter of pipe and flow per second.

PISTONS

Aluminum. Aluminum Pistons, Frank Jardine and Ferdinand Jehle. Jl. Soc. Automotive Engrs., vol. 8, no. 5, May 1921, pp. 397–403, 9 figs. Survey of recent developments in construction of aluminum pistons, and suggestions in regard to their design.

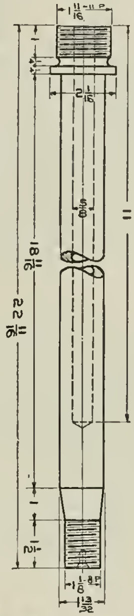
Aluminum Pistons, Frank Jardine and Ferdinand Jehle. Aerial Age, vol. 13, no. 11, May 23, 1921, pp.

The Best Production Methods Are the Most Economical



There is only one *best* method in turret lathe practice. Our Engineers are constantly studying and experimenting to reach that best method and keep our turret lathes up to their high standard.

The results of their study and experimenting are yours to apply to your production problems. Just write us and we'll send one of our engineers to consult with you. He may be able to save you considerable money by suggesting a tool or two or perhaps by re-arranging the tools you have. This is part of our service to you.



Turret Lathes from 4½" x 44"—21" Swing to ⅝" x 4"—10" Swing.

A. W. & S. No. 3-A finishes one of these Air Brake Pump Pistons of cold rolled stock every 20 minutes in an eastern railroad shop. This is a difficult railroad job.

ENGINEERING INDEX (Continued)

250–253, 8 figs. Tests conducted to measure operating temperatures of pistons on Liberty engines. (Concluded.)

Machining Methods. Machining Motor Pistons, C. H. Dengler. Machy. (N. Y.), vol. 27, no. 9, May 1921, pp. 878–879, 3 figs. Successive steps and equipment employed in machining pistons for high-grade automobile.

PLANING

Production Systems. Production Planing in Machine Tool Plants. Machy. (N. Y.), vol. 27, no. 9, May 1921, pp. 833–837, 4 figs. Efficiency factors in production planing. Points to observe in obtaining maximum output from planers.

POLES, WOODEN

Preservative Treatment. The Impregnation of Wooden Poles for Long-Distance Stations (Aufgaben und Ziele der Imprägnierung von Holzmasten für Ueberland-Zentralen), Friedrich Moll. Zeit. für angewandte Chemie, vol. 34, no. 19, Mar. 8, 1921, pp. 81–84, 7 figs. Notes on nature of wood impregnation and experiences in recent years.

The Impregnation of Wooden Poles from an Economic Standpoint (Die Wirtschaftlichkeit der Imprägnierung hölzerner Leitungsmasten), Friedrich Moll. Elektrische Kraftbetriebe u. Bahnen, vol. 19, no. 6, Mar. 24, 1921, pp. 61–63, 3 figs. Four different impregnation processes are recommended.

PORTS

Dunkirk. The Port of Dunkirk. Bulletin Technique du Bureau Veritas, vol. 3, no. 4, April 1921, pp. 91–93, 2 figs. Mechanical equipment for handling cargo.

POWER GENERATION

Victoria, Australia. Power for Victorian Industries. Supp. to Indus. Australian & Min. Standard, Mar. 17, 1921, 79 pp., 77 figs. Electric power scheme authorized and initiated by state government of Victoria and being carried out effect by Victorian commission. Scheme involves development of water power and utilization of brown-coal deposits.

PROPELLERS, SHIP

Manufacture. Propellers Cast in British Shop, Wesley J. Lambert. Foundry, vol. 49, nos. 9 and 10, May 1 and 15, 1921, pp. 351–355, 9 figs., and 391–396, 6 figs. Physical properties of several bronzes used for propellers given. Details of pattern equipment including striking board illustrated and methods of securing correct pitch described. Method of making cope. Melting methods and pyrometric control.

The Manufacture of High-Class Marine Propellers, Wesley J. Lambert. Trans. Inst. of Mar. Engrs., vol. 32, Mar. 1921, pp. 419–457 and (discussion) pp. 457–470, 12 figs. Practice at works of Deptford & Charlton, England.

PULVERIZED COAL

Dust Explosions. How to Protect Pulverized-Coal Plants From Dust Explosions and Fires. Coal Age, vol. 19, no. 17, April 28, 1921, pp. 746–749. Vacuum system should remove dust from air in building; driers should not be heated excessively; air supply for burning coal should be kept from forcing its way into coal supply line.

[See also BOILER FIRING, Pulverized Coal; BOILERS, WATER-TUBE, Tests.]

PUMPING STATIONS

Air-Lift. A Modern Air-Lift Pumping Plant, John Oliphant. Ry. Maintenance Engr., vol. 17, no. 5, May 1921, pp. 172–174, 5 figs. Installation of Philadelphia & Reading Railway at Telford, Pa. 100 gal. are pumped per min. from well 350 ft. deep, 10 in. in diameter.

PUMPS

Exeter Rotary. By Movement of a Rotor Three Spaces Enlarge and Contract, Thus Drawing and Expelling Water. Coal Age, vol. 19, no. 18, May 5, 1921, pp. 805–806, 2 figs.

New Type Exeter Rotary Pump Works on Novel Principle and Wears But Little, S. H. Farkas. Nautical Gaz., vol. 101, no. 19, May 7, 1921, pp. 597–609, 4 figs. Underlying principle of operation is variant of square-hole drilling device in which triangular bit functions inside restraining square former of equal size. Irregular spaces, increasing and diminishing in volume as two rotate together, admit and eject fluid.

Mercury Vapor. A Mercury Vapor Pump (Quecksilberdampfpumpe nach W. Friedrichs). Zeit. fur angewandte Chemie, vol. 34, no. 11, Feb. 8, 1921, p. 46, 1 fig. Details of pumps constructed by Greiner & Friedrichs Glass Works, Stützerbach.

Submersible. Submersible Electric Pumps. Iron & Coal Trades Rev., vol. 102, no. 2771, April 8, 1921, pp. 493, 3 figs. Pumps manufactured by Submersible Motors, Ltd., Middlesex, England.

Vacuum. Dry-Vacuum Pump Capacity Tests, Snowden B. Redfield. Mech. Eng., vol. 43, no. 5, May 1921, pp. 315–318, 4 figs. Method employing low-pressure nozzle for air measurements. Typical volumetric-efficiency curves.

PUMPS, CENTRIFUGAL

Pullen. A New Low Lift Centrifugal Pump. Machy. Market, no. 1067, April 15, 1921, p. 29, 2 figs. Pullen low-lift pump. Impeller member has vanes shrouded both sides, also impeller member and casing are fitted with renewable wearing rings.

PYROMETRY

Industrial Applications. Pyrometric Practice, Paul D. Foote, C. O. Fairchild and T. R. Harrison. U. S. Dept. of Commerce, Technologic Papers, Bur. of Standards, no. 170, Feb. 16, 1921, 326 pp., 185 figs. Survey of practical methods in use in industries in 1920.

RADIOMETALLOGRAPHY

Developments. X-Rays and Their Industrial Applications. Engineering, vol. 111, no. 2884, April 8, 1921, pp. 412–415, 10 figs. Developments in radiometallographic examination of materials.

RAILS

Electric Welding. See ELECTRIC WELDING, Rails.

Fractures. Internal Fractures in Steel Rails, Henry S. Rawdon. Engineering, vol. 121, no. 2885, April 15, 1921, pp. 470–471, 2 figs. Microscopic examinations of "transverse fissures." (Abstract.) Paper read before Faraday Soc.

Standardization. New Standard Rail Sections for French Roads. Ry. Age, vol. 70, no. 19, pp. 1129. Four sections adopted are 26-kg. section for narrow-gage tracks, 36-kg. section for light traffic, standard-gage lines, 46-kg. section for light traffic, standard-gage lines and 55-kg. section for use in tunnels where action of moisture and smoke results in rapid loss of metal.

RAILWAY ELECTRIFICATION

Economics. Economic Aspect of Railway Electrification, A. H. Armstrong. Gen. Elec. Rev., vol. 24, no. 5, May 1921, pp. 405–413, 26 figs. Electrification advocated as means for solving national transportation problem.

Electrification of Steam Roads an Economic Necessity, A. H. Armstrong. Elec. Rev., (Chicago) vol. 78, no. 19, May 7, 1921, pp. 723–727, 2 figs. Economies in fuel and labor effected by change to electric motive power.

Rational Electrification of Steam Railroads, George R. Henderson. Ry. Age, vol. 70, no. 17, April 29, 1921, pp. 1037–1038, 1 fig. Method for determining what values of profile and traffic density make electric operation desirable.

Switzerland. Electrification of St. Gotthard Line, Switzerland, Hans W. Schuler. Ry. Age, vol. 70, no. 19, May 13, 1921, pp. 1107–1112, 13 figs. Line extends from Lucerne to Chiasso on Italian border, distance of 180 miles. There is average grade of 2.5 per cent for 30 miles. Current at 15,000 volts is supplied to locomotives.

RAILWAY MAINTENANCE

Methods. Developing Thoroughness and Permanency. Ry. Maintenance Engr., vol. 17, no. 5, May 1921, pp. 160–164, 4 figs. Engineering and maintenance methods of Lackawanna Railroad.

RAILWAY MOTOR CARS

Diesel-Electric. Diesel-Electric Cars (Les automotrices, Diesel-électriques), Lucien Pahin. Industrie Électrique, vol. 30, no. 692, April 25, 1921, pp. 145–150, 5 figs. Motor cars used in Swedish railways.

RAILWAY OPERATION

Cost Accounting. The earnings of Individual Passenger Trains, T. W. Mathews. Ry. Age, vol. 70, no. 16, April 22, 1921, pp. 981–983, 4 figs. Method for determining whether selected trains pay out of pocket or other costs.

Freight Trains. Effect of Train Speed on Energy Consumption, G. S. Chiles and R. G. Kelley. Ry. Age, vol. 70, no. 18, May 6, 1921, pp. 1083–1084, 2 figs. Charts showing relation between resistance and speed for various average weights per car.

Train Control. Train Operation and Automatic Train Control, J. B. Latimer. Ry. Age, vol. 70, no. 16, April 22, 1921, pp. 977–979. Caution signals, property located with audible signals suggested as means of remedying collision problem.

Train Despatching. A Complete Train Despatching System. Ry. Signal Engr., vol. 14, no. 5, May 1921, pp. 184–187, 4 figs. Practice of Lancashire & Yorkshire Ry., England. All train movements are controlled from one center office. From Modern Transport, Lond.

RAILWAY REPAIR SHOPS

Electric Welding. Railroad Shop Notes, S. Ashton Hand. Am. Mach., vol. 54, no. 18, May 5, 1921, pp. 773–777, 19 figs. Repairs on broken cylinders by electric welding. Gage for setting half-cranks on Walschaerts valve gears.

RAILWAY SIGNALING

Overrunning Signals. Means for Preventing Overrunning Signals Standing at Danger, H. Mollering. Bul. Int. Ry. Assn., vol. 3, no. 4, April 1921, pp. 419–430, 1 fig. Signaling systems used by German Railways. Paper read before Electrotechnical Soc. of Dresden.

RAILWAY SWITCHES

Control. Outlying Switch Control Facilities Train Movements, C. C. Anthony. Ry. Age, vol. 70, no. 18, May 6, 1921, pp. 1077–1079. Development of low-voltage mechanisms controlled from central point.

Interlocking. New Interlocking on the Boston Elevated, W. C. Smith. Ry. Signal Engr., vol. 14, no. 5, May 1921, pp. 173–178, 10 figs. Electropneumatic plant with A. C. control and color light signals gives speed-signaling indications.

RAILWAY TIES

Reinforced-Concrete. The Ickes Railway Tie. Concrete, vol. 18, no. 5, May 1921, pp. 252–253, 10 figs. Main feature consists of lateral enlargements immediately under rail, making longitudinal support of rail at this point 21 in. instead of 8 in. for wooden tie. Tie is made in three parts, which are connected and drawn together by means of 3 8-in. by 2-in. steel bar.

Steel vs. Wood. Steel Sleepers Compared with Wood Indian Eng., vol. 69, no. 15, April 9, 1921, p. 203. Empirical formula for computing relative economy of using steel or wooden ties, obtained from records of service of both of these types of ties in the Baden Ry., Germany.

RAILWAY TRACK

Standardization of Material. The Standardization of Material in France and in Germany (Die Normalisierung des Oberbaumaterials in Frankreich und in Deutschland), P. Müller. Elektrische Kraftbetriebe u. Bahnen, vol. 19, no. 6, Mar. 24, 1921, pp. 63–65. Comparison of relative merits of both systems. Whereas in Germany the standardization committee is a voluntary organization and no one is compelled to adopt the established standards, in France the standardization commission is appointed by Bureau of Public Works and Bureau of Trade.

Tie Plates. Service Stresses in Tie Plates, E. P. Gowing. Ry. Rev., vol. 68, no. 17, April 23, 1921, pp. 644–645 and 650–651, 4 figs. Graphs showing distribution of pressure. From Indian Engineering.

Weed Burners. Southern Road Develops High Power Weed Burner. Ry. Age, vol. 70, no. 17, April 29, 1921, pp. 1033–1034. Apparatus developed in shops of Texas & Pacific. Heat at temperature of 1400 to 1500 deg. fahr. is blown upon vegetation beneath hood 38 ft. long suspended over track, giving length of contact sufficient to destroy vegetation while burner is moving five miles per hour.

REFRIGERATING PLANTS

Operation. Refrigerating Plant Economies and Capacities, I. L. Kentish-Rankin. Power Plant Eng., vol. 25, no. 9, May 1, 1921, pp. 471–477, 8 figs. Methods for increasing economy and capacity of plant.

RESEARCH

Industrial. A Modern Research Laboratory. Automobile Eng., vol 11, no. 150, May 1921, pp. 176–177, 7 figs. Devices which have been evolved at industrial research laboratories operated by Rudge-Whitworth, England.

The Central Research Laboratory of the General Motors Company, J. Edward Schipper. Automotive Industries, vol. 44, no. 17, April 28, 1921, pp. 900–901, 1 fig. Occupies building 1000 ft. long by 270 ft. wide in Moraine City, suburb of Dayton, and is operated as independent unit of G. M. C. but in coöperation with various automobile and parts plants of company, under direction of C. F. Kettering and staff of specialists.

The Conduction of Research, F. H. Norton. Sci. Monthly, vol. 12, no. 5, May 1921, pp. 424–433. Economical advantages of industrial research. Procedure in carrying out research.

The Products of a Works Laboratory. Engr., vol. 131, no. 3408, April 22, 1921, pp. 430–431, 10 figs. Apparatus used in work done at research laboratory in Conventry works of Rudge-Whitworth, England.

Government-Conducted. Scientific and Engineering Work of the Government, Its Cost and Its Value, E. B. Rosa. Eng. & Contracting, vol. 55, no. 20, May 18, 1921, pp. 487–490. Activities of scientific and engineering branches of national Government, with figures relating to economic value of such work. Paper read before Washington Section, The American Society of Mechanical Engineers.

RIVETS

Design. Rivet-Head Shapes (Nietkopfformen) W. Schulz. Elektrotechnische Rundschau, vol. 38, no. 4, Feb. 21, 1921, pp. 21–24, 18 figs. Determination of weight of rivet heads, and of length of radii of arcs forming contour of sections of round-head rivets.

ROCK DRILLS

Rotary Electric. The New Pillar Drill of the Siemens-Schuckert Works (Die neue Säulendrehbohrmaschine der Siemens-Schuckertwerke), H. Baumer. Kali, vol 15, no. 6, Mar. 15, 1921, pp. 94–100, 11 figs. Details of latest improved type of Siemens-Schuckert drill, the GBD 3000, with 3-phase motor requiring 1.65 kw. Advantages and useful possibilities.

ROLLING MILLS

Electrically Driven. Some Methods of Obtaining Adjustable Speed with Electrically Driven Rolling Mills, K. A. Pauly. Gen Elec. Rev., vol. 24, no. 5, May 1921, pp. 422–432, 15 figs. Discussion of Merits of Scherbius system of speed control, both single range and double range in which slip energy of main motor is returned to system as electric energy. Comparison is made with Kraemer or synchronous converter system in which slip energy is returned to main motor shaft.

Rerolling Rails. Rerolling Rails at Sweet's Steel Co., Sidney G. Koon. Iron Age, vol. 107, no. 19, May 12, 1921, pp. 1227–1232, 8 figs. Recovery of 80 per cent of old tonnage. Rails split for rolling angles and flats for fence posts and bedsteads.

Roll Design. Foreign Methods of Roll Design, H. R. Ronnebeck. Iron & Coal Trades Rev., vol. 102, no. 2771, April 8, 1921, pp. 490–492, 18 figs. Comparison of German and American practices. Paper read before Cleveland Insto. Engrs.

MAKING EFFECTIVE USE OF RADIANT ENERGY

The importance of Radiant Energy in boiler and stoker practice is strongly emphasized by Prof. A. G. Christie of Johns Hopkins University in an article in "Power" for April 12.

The conclusions reached are:

> "First, that direct radiation is an important source of heat in boiler furnaces which should be carefully considered in both design and operation.
>
> Second, that the highest possible furnace and fuel-bed surface temperatures should be maintained, so as to emit the greatest amount of radiant energy; and that furnace design and operation should be studied to insure *continuous removal of ash and cinder from this hot surface.*
>
> Third, that the greatest possible amount of dull metallic boiler surface should be arranged *to "see" the fire:* that is, to receive this radiant energy directly, and that these surfaces must be kept free of dust and cinders by effective cleaning devices."

The Riley Stoker with its continuous automatic ash discharge insures the continuous removal of ash and cinder from the fuel bed so that high surface temperature can be constantly maintained.

With the Riley Stoker no arches are required for combustion purposes, therefore the boiler tubes can "see" *all* of the fuel bed. Note the illustration below.

The Riley Stoker is designed to most effectively use all the available radiant energy.

Full details of Riley Stoker Design are shown in Catalog A-7—Ask for it.

The Sanford Riley Stoker Co. is now prepared to equip new Riley Stokers with coal agitators licensed under the Negus-Tiffany patents.

S

SCRAPING MACHINES

Compressed-Air. The Use of Scrapers in Metal Mines, Lucien Eaton. Compressed Air Mag., vol. 26, no. 5, May 1921, pp. 10065–10075. Structural characteristics of typical scraping machines.

SCREW THREADS

Methods of Producing. Various Methods of Producing Threads, J. H. Moore. Can. Machy., vol. 25, no. 17, April 28, 1921, pp. 25–31, 23 figs. Threading locomotive set screws. Steel axles. Special nuts. Tractor axles; worms; lead screws; fine pitch threads and internal threads.

SCREWS

Gaging. Gauging and Fine Measurements—I, A. C. Wickman. Machy. (Lond.), vol. 18, no. 446, April 14, 1921, pp. 52–55, 8 figs. Application to production of screws.

SLAG

Utilization and Agriculture. Basic Slags: Their Production and Utilization in Agriculture. Trans. Faraday Soc., vol. 16, no. 2, Dec. 1920, pp. 261–335. Symposium. Papers presented were: The Utilization of Basic Slag; The Physical Chemistry of Basic Slags; The National Aspects of the Case for Increasing Supplies of Basic Slag; The Demand for Basic Slag; Basic Slag and Its Place in the Development of Agriculture; A Comparison of the Effect of Various Types of Open Hearth Basic Slags on Grassland; Solubility of Basic Slags; The Improvement of Low Grade Basic Slag; Formation of Basic Slag in the Manufacture of Steel.

SPRINGS

Design. Formulas for Spring Design, Edward Jacobi. Machy. (N.Y.), vol. 27, no. 9, May 1921, pp. 882–884, 4 figs. Empirical formulas tried out in designing plants of Milwaukee manufacturers.

Helical. Design of Helical Springs, Joseph Kaye Wood. Am. Mach., vol. 54, no. 18, May 5, 1921, pp. 780–784, 3 figs. Importance of and factors entering into "material index." Determination of torsional modulus of elasticity. Control of unit fiber stress.

Leaf. Design and Heat Treatment of Leaf Springs, H. E. Hemstreet. Forging & Heat Treating, vol. 7, no. 4, April 1921, pp. 240–242. Times and temperature for hardening and drawing.

Testing. Magnetic Spring Testing, T. Spooner and I. F. Kinnard. Am. Soc. for Testing Matls., advance paper, 8 pp. 3 figs. Apparatus used and results obtained in magnetic tests on helical steel springs. Hysteresis method of testing is believed to furnish ready commercial method of checking quality and heat treatment of finished springs.

Spring Testing. Automobile Engr., vol. 11, no. 149, April 1921, pp. 142–144, 5 figs. Amsler universal machine for testing springs under pressure of from 2 to 100 tons.

STACKS

Steel, Cement-Gun Lining. The Conservation of Steel Stacks Weakened by Corrosion, John V. Schaefer. Eng. World, vol. 18, no. 5, May 1921, pp. 321–323, 5 figs. Reconstruction of corroded steel stack by cement-gun lining.

STAMPING

Typical Operations. The Economics of Drawing and Forming Metals, Robert Holmes. Raw Material, vol. 4, no. 4, April 1921, pp. 124–128, 13 figs. Typical stamping operations. Records of costs.

STANDARDIZATION

Economics. Standardization of Products, Melvin T. Copeland. Bul. Taylor Soc., vol. 6, no. 2, April 1921, pp. 55–64 and (discussion) pp. 64–76. Economical advantages of standardization.

Fillets for Revolving Parts. Standard Fillets for Revolving Parts (Normale Abrundungen an Drehteilen), K. Schenck. Der praktische Maschinen-Konstrukteur, vol. 53, no. 51, Dec. 23, 1920, pp. 436–438, 3 figs. Suggestions for carrying out a standardization system for filleting shoulders of shafts and rounding off the corresponding portion of brasses or bearings in which they revolve.

Machinery. Report of the German Industry Committee on Standards (Mitteilungen des Normenausschusses der Deutschen Industrie). Betrieb, vol. 3, no. 15, Apr. 25, 1921, pp. 207–219, 16 figs. Proposals of Board of Directors for plug gages, limit gages, holders, measuring disks and holders, and end gages. Proposed new standards for circular dies, die caps and holders.

Report of the German Industry Committee on Standards (Mitteilungen des Normenausschusses der Deutschen Industrie). Betrieb, vol. 3, no. 14, Apr. 10, 1921, pp. 187–199, 20 figs. Proposal of Board of Directors for holes, keyways and arbors for cutters, reamers and countersinks; hand screw taps for Whitworth, metric and pipe threads; nut taps; screw die taps; hand jaw and machine jaw taps. Proposed standard for molded pieces for drain pipes.

The Interdependence of Standards with Special Regard to Preferential Dimensions (Die Abhängigkeit der Normen voneinander unter besonderer Berücksichtigung der Vorzugsmasse), R. Koch. Betrieb, vol. 3, nos. 13 and 14, Mar. 25 and Apr. 10, 1921, pp. 94–101 and 106–108, 10 figs. Presents table containing series of preferential dimensions developed by working committee for standard numerals and explains their practical application. Report of Federation of German Works Engrs.

STEAM

Superheated, Specific Heat of. The Determination of the Specific Heat of Superheated Steam from Throttling Tests (Ueber die Bestimmung der spezifischen Wärme des überhitzten Wasserdampfes aus Drosselversuchen) Karl Hencky. Zeit. des Bayerischen Revisions-Vereins, vol. 25, nos. 6 and 7, Mar. 31 and Apr. 15, 1921, pp. 41–43 and 52–54, 2 figs. Critical discussion of tests by Grindley and Griessmann; notes on accuracy obtainable with throttling tests. Recommendations based on experiences with the throttling calorimeter.

STEAM-ELECTRIC PLANTS

France. French Electric Plant, Carroll F. Merriam. Nat. Engr., vol. 25, no. 5, May 1921, pp. 214–217, 3 figs. Steam-electric plant of gas company of Lyons.

Philadelphia. Compact Reinforced-Concrete Generating Station at Philadelphia. Elec. World, vol. 77, no. 21, May 21, 1921, pp. 1145–1151, 18 figs. Steam-electric station with generating capacity of 180,000 kw. Attention is directed to coal-handling facilities and furnace construction.

STEAM METERS

New Types. Power Consumption and Steam Meters (Ueber Betriebskontrolle und Dampfmesser), Anton Gramberg. Zeit. des Vereines deutscher Ingenieure, vol. 65, no. 15, Apr. 9, 1921, pp. 391–393, 4 figs. Suggestions for equipment and superintendence of factories operating with waste heat. Experiences with different types of steam meters and description of two new types.

STEAM POWER PLANTS

New Plant. A Plant Built for Service. Power Plant Eng., vol. 25, no. 9, May 1, 1921, pp. 449–454, 11 figs. Plant supplying steam for power and heating purposes.

STEAM SHOVELS

Loading Slag with. Operations of the Birmingham Slag Company. Excavating Engr., vol. 15, no. 5, May 1921, pp. 151–154, 6 figs. Company is operating eight steam shovels in and around Birmingham, loading slag. Description of plants at Ensley and Alabama City, Ala.

STEAM TURBINES

Developments. Some Recent Developments in Large Steam Turbine Practice, K. Baumann. Eng., vol. 111, nos. 2884, 2885, 2886, 2887, 2888 and 2889, Apr. 8, 15, 22, 29, May 6 and 13, 1921, pp. 435–439, 449–453, 501–504, 532–535, 567–571 and 597–600. 38 figs. Apr. 8: Outline of turbine practice from 1912 to 1921 based on published records and other information, indicating circumstances which have resulted in "race for maximum output at highest possible speed." Apr. 15: Factors affecting development of large turbines Apr. 22: Basis of calculations for improvement in heat consumption possible with improved steam conditions. Apr. 29: Economical rating of given turbine frame. May 6: Comparison of different types of turbo machines. May 13: Tests on steam consumption of large turbines. Paper read before Instn. Elec. Engrs.

Lubrication. Keeping Steam Turbine Lubricating Oil in Good Condition, Charles H. Bromley. Gen. Elec. Rev., vol. 24, no. 5, May 1921, pp. 414–421, 7 figs. Various processes employed, including batch system, continuous filtration, and continuous by-pass are described, and list of requirements of efficient oil filtration system is given.

STEEL

Alloy. See ALLOY STEELS.

Automobile. Further Notes on Automobile Steels, W. H. Hatfield. Automobile Engr., vol. 11, no. 149, April 1921, pp. 153–158, 4 figs. Experiments at Brown-Firth Research Laboratories to establish actual fatigue range of different steels.

Carbon Determination. Electrolytic Resistance Method for Determining Carbon in Steel, J. R. Cain, L. C. Maxwell. U. S. Dept. of Commerce, Technologic Papers, Bur. of Standards, no. 141, Dec. 6, 1919, 21 pp. 6 figs. Method for determining carbon dioxide by absorbing it in barium hydroxide solution and measuring resistance change of solution in relation to its concentration. Suitable absorption vessel with electrolytic resistance cell incorporated.

Intercrystalline Fracture. Inter-Crystalline Fracture in Steel, D. Hanson. Engineering, vol. 121, no. 2885, April 15, 1921, pp. 467–469, 7 figs. Examination of photomicrographs. It is concluded that there is no essential difference between iron and steel and non-ferrous metals in regard to season cracking. (Abstract.) Paper read before Faraday Soc.

Inter-Crystalline Cracking of Mild Steel in Salt Solutions, J. A. Jones. Engineering, vol. 121, no. 2885, April 15, 1921, pp. 469–470, 7 figs. Photomicrographic and chemical analyses. It is believed one of determining factors in production of cracks is presence of internal or applied tensile stress, and fracture occurs only when these stresses are above certain value. Condition of slightly elevated temperature alone was not found to be responsible for producing cracks in internally stressed steel. (Abstract.) Paper read before Faraday Soc.

Piping and Segregation. Shrinkage-Hole Formation and Segregations in Steel Ingots (Ueber Lunkerbildung und Seigerungserscheinungen in silizierten Stahlblöcken), A. Brüninghaus and Fr. Heinrich. Stahl u. Eisen, vol. 41, no. 15, Apr. 14, 1921, pp. 497–510, 17 figs. Marked difference in casting methods employed with steel with silicon added were not observed. Results of investigations and conclusi Discussion.

Rock-Drill. Breakage and Heat Treatment of Ro Drill, Benjamin Tillson. Min. & Metallurgy, 173, May 1921, pp. 38–39 and 42–43, 4 figs Serv tests on 7 brands of rock drill steel. 246 pieces of 271 were broken during tests; 25 pieces avera 114 ft. without breaking.

Shipbuilding. Steel and Iron for Shipbuild Purposes, Horace Holden Thayer. Mar. E vol. 26, no. 5, May 1921, pp. 370–375. Notes practice, requirements, specifications, methods ordering shipments, etc.

Tests. Impact Tests on Cast Steel, F. C. Langenb Am. Soc. for Testing Matls., advance paper, 11 4 figs. Tests made to determine effect of phosph upon physical properties of cast steel, also effec heat treatment upon acid open-hearth cast st

Tool. Action of Internal Stress on Tool Steel Neil Greenwood. Engineering, vol. 111, no. 2 April 29, 1921, pp. 535–537, 1 fig. Origin of inte stresses in pure metals and alloys are grouped in main classes: those due to distortion by cold worl and those resulting from suppression of phase cha by rapid cooling. Conditions governing harde of steel are set out in detail and volume cha causing internal stresses are analyzed. Phenom of spontaneous change are examined in light of sults published by Matsushita. Paper read at j meeting of Faraday Soc. with other instituti

Tungsten. Structure of Tungsten Steels. Ch & Metallurgical Eng., vol. 24, no. 17, April 27, 1 pp. 745–748, 18 figs. Review of Honda and M kami's work, presenting their principal conclus as to structure and constitution of tungsten iron bon alloys. Reactions between iron tungstide iron and tungsten carbides.

STEEL, HEAT TREATMENT OF

Hardening. The Hardening of Steel (Ueber Härten des Stahls), B. Strauss. Betrieb, vol no. 14, Apr. 10, 1921, pp. 400–405, 18 figs. cusses theory of hardness of steel based on result most recent researches, and its dependence on c position, temperature and speed of cooling Origin of pressure cracks and the close relation between volume and hardness of steel.

Quenching Cracks. On Cause of Quenching Cr Kotaro Honda, Tokujiro Matsushita and Sakae I Engineering, vol. 111, no. 2889, May 13, 1921, 595–597, 9 figs. It is concluded from tests tha quenched steel a certain amount of austenite is erally present intermingled in martensite. Amo of austenite increases as quenching tempera increases. Quenching cracks occur in small piece steel when hardness in central portion is much gre than in periphery. Cracking is attributed to st caused by difference in specific volumes of auste and martensite. Paper read before Iron and S Inst.

Screw Stock. Heat Treatment of Screw St A. A. Blue. Forging & Heat Treating, vol. 7, n May 1921, pp. 265–267, 7 figs. Prolonged treatn at high temperatures is necessary to refine llan structure caused by cold rolling. Greatest p bilities lie in case carbonizing.

STEEL MANUFACTURE

Chart. Development of Iron Ore Into Iron and S S. C. Dickerhoff, Jr. Blast Furnace & Steel Pl vol. 9, no. 5, May 1921, pp. 318–319, 1 fig. C illustrating processes of steel manufacture.

Converters. Calculation of the Additions in S Converters (Berechnung der Zusätze beim Kl konverter), Bernhard Osaan. Giesserei-Zeit vol. 18, no. 5, Mar. 1, 1921, pp. 69–71, 1 fig. Met of determining manganese and silicon conten additions to steel.

Direct Process. Another Direct Process for S Making, Herbert Lang. Iron Age, vol. 107, no. May 12, 1921, pp. 1237–1238. Mixture conta in retort and charged into reverberatory furn Steel produced in melting compartment. Metho Direct Steel Process Co. Inc.

STEEL MILLS

Czecho-Slovakia. The Steel Works of Czecho-vakia. Am. Mach., vol. 54, no. 19, May 12, 1 pp. 826–829, 9 figs. Steel mills have melting pacity of 8000 tons per month. Electric furn are used.

Electric Drive. A New Balanced Sheet Mill D Josef Hirschmann. Blast Furnace & Steel Pl vol. 9, no. 5, May 1921, pp. 328–329, 1 fig. D consists of 25-hp. motor running at 750 r.p.m. dir connected to speed reducing gear transmission means of flexible coupling.

Handling Materials. Mechanical Handling of S Mill Material, C. F. Poppleton. Blast Furnace Steel Plant, vol. 9, no. 5, May 1921, pp. 291– 12 figs. Methods at Midland plant of Pittsb Crucible Steel Co.

Lorraine. The Thyssen Works, Hagondange, Dahl. Iron & Coal Trades Rev., vol. 102, no. 2 April 29, 1921, pp. 589–595, 10 figs. Descriptio steel works. Translated from Stahl und Ei

Russia. The Donetz Region of the Bolshevic Gov ment—II, M. Ullrich. Blast Furnace & Steel Pl vol. 9, no. 5, May 1921, pp. 314–316. Notes iron and steel industry in Russia.

STOKERS

Underfeed. Development and Application of Un feed Stoker, Edward Rahm, Jr. Proc. Engrs. of Western Pa., vol. 37, no. 1, Feb. 1921, pp. 2 and (discussion) pp. 53–68, 16 figs. History developments in U. S.

ENGINEERING INDEX (Continued)

STRESSES

Buckling and Bending. Buckling and Bending (Knickung und Biegung), H. Ellerbeck. Zentralblatt der Bauverwaltung, vol. 41, no. 25, Mar. 26, 1921, 3 figs. Discussion of approximate formulas for buckling resistance and bending stress.

Determination with Polarized Light. The Determination of Stresses in Stressed Bodies with the Aid of Polarized Light (Die Bestimmung der Spannungen in beanspruchten Körpern mit Hilfe polarisierten Lichtes), H. Schulz. Betrieb, vol. 3, no. 14, Apr. 10, 1921, pp. 405–412, 12 figs. Discusses laws of propagation of light in anisotropic bodies and apparatus for observation of double refraction caused by stress. Examples of different cases of stressed bodies, such as influence of external pressure or tensile forces, irregularities of structure, and temperature influence.

Photoelastic Analysis. Photo-Elasticity for Engineers—V, E. G. Coker. Gen. Elec. Rev., vol. 24, no. 5, May 1921, pp. 455–466, 14 figs. Stress-strain properties of nitro-cellulose and law of its optical behavior.

SUBMARINES

Detection. The Nash Fish for Submarine Locating. Elec. Times, vol. 59, no. 1541, April 28, 1921, pp. 403–404, 2 figs. Measurements by rotating transmitters.

SUPERHEATERS

Design. Modern Practice with Steam Superheaters and Their Fields of Use, H B. Oatley. Jl. Eng. Inst. of Canada, vol. 4, no. 5, May 1921, pp. 289–300, 17 figs. Notes on design of superheaters, including detailed study of types of installations, application and use, also comparative tables of performance with saturated and superheated steam.

Flue Tubes. The Manufacture of Flue Tube Superheaters. Engr., vol. 131, no. 3408, April 22, 1921, pp. 438–440, 10 figs. Procedure at works of Marine and Locomotive Superheaters, Westminster, England.

T

TERMINALS, LOCOMOTIVE

Mallet Locomotives. Improving Terminals for Mallet Operation. Ry. Age, vol. 70, no. 18, May 6, 1921, pp. 1063–1068, 11 figs. Locomotive terminal of Norfolk & Western Railroad at Roanoke, Va.

Operation. Intensive Operation of Locomotive Terminals, L. G. Plant. Ry. Rev., vol. 68, no. 17, April 23, 1921, pp. 641–644, 2 figs. Urges standardization of terminal equipment and statistical control of terminal operation.

TERMINALS, MARINE

Mechanical Equipment. The Handling of Goods at the Port of Manchester Warehouses. Engineering, vol. 111, nos. 2888, and 2889, May 6, and 13, 1921, pp. 541–544, 23 figs., and 576–577, 12 figs., partly on suppl. plate. There are 44 distinct warehouses which can accommodate about 500,000 tons of perishable goods under cover, besides unlimited quantity in open storage. Methods of handling wool, material in bags, cotton, etc., are described. Cold stores with capacity of 1,000,000 cu. ft.

TERMINALS, RAILWAY

New York. An Automatic Terminal Railway for New York. Eng. & Contracting, vol. 55, no. 20, May 18, 1921, pp. 491–495. Plan of steam and electric yard in New Jersey for joint use of New Jersey railroads and automatic-electric system. Scheme developed by New York, New Jersey Port and Harbor Development Commission.

TESTING MACHINES

Bradley-Richards. A New Metal Testing Machine. Eng. Production, vol. 2, no. 29, April 21, 1921, pp. 512, 2 figs. Bradley-Richards hydraulic testing machine.

Brinell Hardness Testing. Modern Testing Machines (Neuere Prüfmaschinen), E. Irion. Zeit. des Vereines deutscher Ingenieure, vol. 65, no. 13, Mar. 26, 1921, pp. 315–320, 21 figs. Deals with hardness-testing machines. Notes on importance of the Brinell test and the Brinell testing machines of the Dusseldorf Machine Corp.; measuring devices; testing machines for large and heavy pieces; relation between degree of hardness and tensile strength degree of hardness with different loads. Recommendation for a standard ball with diameter of 6.35 mm.

Compression. 500-Ton Compression Testing Machine. Engineering, vol. 111, no. 2886, April 22, 1921, pp. 488–490, 5 figs. Installed in engineering department of British Nat. Physical Laboratory. Machine is intended for making compression tests on stone and concrete and embodies unique application of Amsler principle of load measurement.

TESTS AND TESTING

Brinell Hardness Testing. Ball Testing of Materials for Hardness, Brinell Test (Etude sur l'essai de dureté à la bille. Essai Brinell) R. Guillery. Revue de Métallurgie, vol. 18, no. 2, Feb. 1921, pp. 1–110, 12 figs. Researches on elimination of time influence Testing for hardness with ball receiving pressure by impact.

Impact. Tests Under Repeated Impact (Quelques Essais aux chocs répétés), Leon Guillet. Revue de Métallurgie, vol. 18, no. 2, Feb. 1921, pp. 96–100. It was established that rupture produced by repeated impact takes place by progressive fissuration.

TEXTILE MACHINERY

Machine Running Recorder. Machine Running Recorder. Engineering, vol. 111, no. 2889, May 13, 1921, pp. 580–582, 9 figs. Machines constructed for controlling operation of textile machines. Each machine is connected with instrument in such a way that an electric circuit is completed when machine stops and blank line is started on record sheet.

TEXTILES

Microscopy. The Microscopy of Textiles, F. J. Hoxie. Textile World, vol. 59, no. 16, April 16, 1921, pp. 59 and 61, 3 figs. Recommends coöperative study for needed development. Paper read before Textile Division, Am. Soc.Mech. Engrs.

Winding. The Art of Winding, George W. Foster. Textile World, vol. 59, no. 16, April 16, 1921, pp. 51 & 61. Its relation to production, cost and quality in textile industry. Paper read before Textile Division, Am.Soc.Mech.Engrs.

TIRES, RUBBER

Pneumatic. Design and Manufacture of Pneumatic Motor Tires, Colin Macbeth. Practical Engr., vol. 63, no. 1781, April 14, 1921, pp. 228–232, 12 figs. Outline of manufacturing systems. Paper read before Instn. Automobile Engrs.

Truck, Pneumatic. Use of Pneumatics Limited on Trucks of More Than 3½-Ton Capacity. Automotive Industries, vol. 44, no. 18, May 5, 1921, pp. 960–961. Opinions expressed by truck and tire builders in reply to questionnaire.

TRACTORS

Caterpillar. Caterpillar Farm Tractors (Raupenschlepper für landwirtschaftliche Zwecke). Zeit. des Vereines deutscher Ingenieure, vol. 65, no. 14, Apr. 2, 1921, p. 348, 1 fig. New Büssing tractor with slow-speed engine of 55 hp. and capable of traveling up to 6 km. per hr.

Gear for Snow Riding. Cars for Mountains (Chars de montagne), L. Périssé. Nature (Paris), no. 2451, Mar. 26, 1921, pp. 193–195, 5 figs. Typical tractors with running gear adopted for travel on snow-covered road.

Tests. Data on Illinois Tractors. Jl. Soc. Automotive Engrs., vol. 8, no. 5, May 1921, pp. 487–488. Survey made by Division of Farm Mechanics, University of Illinois, comprising records kept by farmers on 68 tractors.

Nebraska Tractor Tests, Oscar W. Sjogren. Jl. Soc. Automotive Engrs., vol. 8, no. 5, May 1921, pp. 391–395, 6 figs. Nebraska tractor law provides that stock tractor of each model and type sold in State shall be tested and passed upon by board of three engineers under State University management.

TUBES

Brass. Internal Stresses in Brass Tubes, H. N. Vaudrey and W. E. Ballard. Metal Industry (Lond.), vol. 18, no. 15, April 15, 1921, pp. 290–292, 6 figs. Experimental investigation of circular tubes containing 70 per cent copper.

Design. Design of a Tube Supporting a High Internal Pressure (Calcul d'un tube supportant une forte pression intérieur), E. Sinard. Arts et Métiers, vol. 1, no. 1, Oct. 1920, pp. 18–20, 8 figs. Formulas for computing stresses.

Seamless. Finishing Process for Seamless Tubes. Iron Age, vol. 107, no. 17, April 28, 1921, pp. 1114–1118, 11 figs. Details of Pilgrim-step finishing process. Working hollow ingot on mandrel, between rolls, in such manner that at each revolution of rolls small portion of ingot is rolled to tube, is principle. Translated from Stahl und Eisen.

On the Manufacture of Seamless Tubes—III, Karl Gruber. Blast Furnace & Steel Plant, vol. 9, no. 5, May 1921, pp. 320–323, 9 figs. Processes of rolling seamless tube in Germany with special consideration of Mannesmann oblique rolling process. Translated from Stahl und Eisen.

TUNNELS

Vehicular. Shield vs. Trench Method for Hudson Vehicle Tubes, C. M. Holland. Eng. News-Rec., vol. 86, no. 18, May 5, 1921, pp. 764–766. Why shield method has been selected in preference to trench method for construction of Hudson River vehicular tunnels between New York and New Jersey.

V

VACUUM

Methods of Production. Methods for the Production and Measurement of High Vacua—VIII, Saul Dushman. Gen. Elec. Rev., vol. 24, no. 5, May 1921, pp. 436–443, 2 figs. Physico-chemical methods.

VALUATION

Railways. An Analysis of the Current Valuation Report on the Kansas City Southern Properties, Samuel W. Moore. Eng. News-Rec., vol. 86, no. 19, May 12, 1921, pp. 818–821. Status of investigation of date. Present announcement of Interstate Commerce Commission includes single sums as "value" but no statement of method. Land acquisition costs apparently disallowed.

VENTILATION

Office Building. Ventilation of the Home Office Building of the Travelers Insurance Company, Hartford, Conn. Am. Architect, vol. 119, no. 2364, April 13, 1921, pp. 459–462, 4 figs. System is composed of two parts, (1) blower section which includes distributing apparatus, and (2) exhaust section which consists of apparatus by means of which used or vitiated air is removed from building. In each of these sections air is propelled through metal ducts and chambers by fans operated by individual electric motors.

VOCATIONAL EDUCATION

Disabled Soldiers. Making Mining Engineers from Disabled Soldiers, W. A. Clark. Eng. & Min. Jl., vol. 111, no. 17, April 23, 1921, pp. 706–708, 3 figs. Project of Federal Board of Vocational Education, Washington, D. C.

The Re-Education of the Disabled, J. Manclark Hollis. Jl. Royal Soc. of Arts, vol. 69, no. 3568, April 8, 1921, pp. 318–324, 5 figs. Work being carried out by Village Centers Council, England.

VOCATIONAL TRAINING

Disabled Workmen. Industrial Rehabilitation—General Administration and Case Procedure. Federal Board for Vocational Education, Bul. no. 64, Mar. 1921, 52 pp. Rehabilitation is considered from point of view of State administrations.

Pennsylvania Bureau of Rehabilitation. Bureau of Rehabilitation Pennsylvania Department of Labor and Industry Report of Activities to January 1, 1921, Bul. Dept. of Labor & Industry, vol. 8, no. 2, Jan. 1, 1921, 30 pp.

W

WAGES

Changes in Industry. Wage Changes in Industry. Nat. Indus. Conference Board, no. 35, Mar. 1921, 52 pp. Survey of wage changes in major manufacturing industries in U. S. from Sept. 1914 to end of 1920.

WATER POWER

Argentina. Hydroelectric Power in Argentina, Leonard Matters. Sci. Am., vol. 124, no. 17, April 23, 1921, pp. 330 and 340, 2 figs. Scheme for generating 125,000 kw. from Eguazu Falls.

Japan. Regulations Governing Development of Water Power in Japan. Elec. World, vol. 77, no. 20, May 14, 1921, pp. 1101–1104, 3 figs. State governors have power to alter designs and rescind concessions. Basis of calculations required. Electric companies have right of eminent domain.

WELDING

Steel. The Welding of Steel, H. Brearley. Engineering, vol. 111, no. 2888, May 6, 1921, pp. 551–554, 12 figs. Welding of steel in relation to occurrence of pipe, blow-holes and segregates in ingots. (Abstract). Paper read before Iron & Steel Inst.

[See also AUTOGENOUS WELDING; ELECTRIC WELDING; ELECTRIC WELDING, ARC; OXY-ACETYLENE WELDING; RAILWAY REPAIR SHOPS, Electric Welding.]

WELDS

Heat Treatment. Effect of Heat Treatment on Metal Arc Welds, James W. Owens, J. H. Ramage and J. A. Watts. Ry. Elec. Engr., vol. 12, no. 5, May 1921, pp. 189–193, 10 figs. Metallographic studies made at U. S. Navy Yard, Norfolk, Va.

Testing. The Desirability of Standardization in the Testing of Welds, F. M. Farmer. Jl. Instn. Mech. Engrs., no. 3, April 1921, pp. 225–240, 5 figs. Standards for evaluating welds are suggested and certain standard procedures are proposed for various mechanical tests.

WELFARE WORK

Restaurants. The Factory Restaurant as a Service Nucleus, Sanford DeHart. Indus. Management, vol. 41, no. 9, May 1, 1921, pp. 338–340. Experience of R. K. LeBlond Machine Tool Co., Cincinnati, O.

WIND TUNNELS

Design. National Advisory Committee's 5-ft. Wind Tunnel, F. H. Norton. Jl. Soc. Automotive Engrs., vol. 8, no. 5, May 1921, pp. 489–495, 16 figs. Tunnel is of venturi type with continuous throat of circular section and there is airtight experimental chamber built about working section in order that small holes may be opened into tunnel while it is running without disturbing airflow.

Intake Bell. Experiments on the Design of Intake Bell for a Wind Tunnel. U. S. War Dept., Air Service Information Circular, vol. 3, no. 217, April 30, 1921, 8 pp. 5 figs. Object was to investigate effect of intake bell on smoothness of flow in wind tunnel. Conclusion reached was that Grimes type intake bell gives best velocity distribution.

McCook Field. Description of the McCook Field Wind Tunnel. U. S. War Dept., Air Service Information Circular, vol. 2, no. 196, April 30, 1921, 8 pp. 6 figs. McCook field wind tunnel is used for high-speed investigations of instruments, aerofoils, etc. Speeds up to 525 m.p.h. are attained.

WOMEN WORKERS

Two-Shift Systems. The Two-Shift System for English Working Women. Monthly Labor Rev., vol. 12, no. 4, April 1921, pp. 92–95. Approval by parliament of bill permitting under certain conditions employment of women in workshops at any time between 6 A.M. and 10 P.M. in shifts averaging not more than 8 hr. for each shift.

WOOD PRESERVATION

Treatment. Modern Wood Impregnation Methods, Friedrich Moll. Eng. Progress, vol. 2, no. 3, Mar. 1921, pp. 55–56, 4 figs. Rüping economic process. Part of oil is forced out again.

MECHANICAL ENGINEERING

Volume 43 August, 1921 Number 8

General Education and the Engineering Profession

By H. E. Miles,[1] New York, N. Y.

POSSIBLY no consequence of the Great War is more portentous than the decision of all the people of civilized nations that hereafter every man shall think for himself, and that no Prussian militarist or other group, however wise, shall think for the rest of society.

With this decision comes the requirement, not that we concern ourselves less with higher education, but more with the common schools and with new avenues of educational advancement, fitted to his circumstances, whereby the average man of whatever age, and the less favored, shall be trained to sound thinking upon social and economic subjects and for better accomplishment than heretofore.

Education is the development of the powers of mind and body, and public education, the taking of the money of all for the education of the children of all, is especially for the development of the social and economic understanding of all.

An idea of the present educational foundation of the American social structure may be gained from the chart of Fig. 1, which includes the total population of the United States under fifty years of age. The irregular line to the left of the chart may be called the death line as it indicates our diminishing population as life advances.

The inner curved line indicates the total school population, and the numbers in the first 6 grades, in the 7th and 8th, in high school, and in college.

It is commonly said that there is nothing of education in the first six grades where only the tools of education, the "Three R's," are acquired with which education is secured later if at all. As nearly half the children leave school at about 14 (in the mill towns of Massachusetts 70 per cent leave by the end of the 5th grade), it may be said that half leave school forever without any real education. There is, moreover, substantially nothing of formal education in "live civics" or in economics taught in the 7th and 8th grades. We may therefore say that education begins in this sense with the dotted line at the 16th year after 70 per cent of the children have left and therefore that our social structure with its great adult population in the large area *A* of the chart has an educational foundation in one corner only, that of the college and high school, rapidly diminishing from this little corner along the curved line from *C* to nothing before reaching *D*, with 43,000,000 wage earners and 20,000,000 of their wives and sisters of the same status in the area *A* who left school by the end of the 6th grade with never an hour of formal instruction in those things which make for understanding of our social institutions, of economics or the means of livelihood.

The inestimable value of this neglected 80 per cent of our citizenship is indicated by the careful testing of some 1,500,000 enlisted men in the recent war, showing that only one-tenth of the genius of our country is college bred, the other nine-tenths running all the way from high school to illiteracy, with 24.9 per cent of our people unable to read an English newspaper and write a letter home. We have been miners finding only one nugget in ten and missing the other nine.

Prof. Irving Fisher estimated, some years ago, the mere money value of the brain and muscle of our working people at $250,000,000,000 to $300,000,000,000, or five times the value of all other natural resources of the country combined. This equals in today's values and population not less than half a trillion dollars, an inconceivable sum. What a chance for engineering is this development of our human resources!

The following quotation from a chart hung on the bulletin board of a great high school, shows the insistence everywhere expressed that there is no chance for the American boy unless he goes to college:

DISTINGUISHED MEN OF AMERICA AND THEIR EDUCATION

With no schooling, of *5 million* only *31* attained distinction.
With elementary schooling, of *33 million* only *808* attained distinction.
With high-school education of *2 million*, *1245* attained distinction.
With college education, of *1 million*, *5768* attained distinction.

WHAT IS YOUR CHANCE?

With us it is "go to college or go to the devil" educationally. Rather, with reasonable encouragement of colleges, we should make equal provision for those who cannot go, by the setting up for wage earners and others in connection with their employment and otherwise, of the equivalent of high schools and colleges adapted to their circumstances, not unmindful of the findings above referred to, that only 30 per cent of our youth have the natural ability that will permit them to go through the present high school however much they try, and that presumably much less than half of this 30 per cent could by any chance go through college.

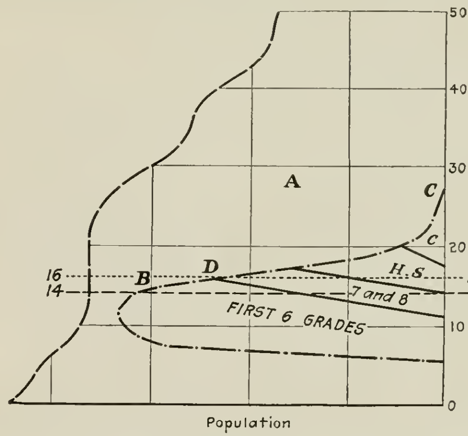

Fig. 1 Total Population and School Attendance, Russell Sage Foundation

Our Lack of Vocational Schools

Is it not an indictment of our intelligence that we provide no opportunities for the education in this wise of the 38,000,000 noted in the first two items of the chart just referred to? Several countries, with Germany leading, have shown the way. By a survey of 105 of Germany's greatest industries, 65 per cent of the men in foremost places in managerial and technical departments were little working boys who quit school at 14, grew up with the right sort of compulsory continuation schools, and later, selectively, enjoyed special technical training with the assistance of their employers and otherwise. Most of the graduates of her technical colleges served under these leaders from work schools and higher vocational schools, of which there are practically none in democratic America. This statement is not an endorsement of the German policy of

[1] Formerly President of Wisconsin State Board of Vocational Education. Address delivered at the session on Training for the Industries, of the Spring Meeting, Chicago, May 23 to 26, 1921, of The American Society of Mechanical Engineers.

class distinction in education, nor of her terrible sin against her common people in withholding instruction in citizenship and inculcating instead blind obedience to authority. It is for us to give the best possible education to those who will not, and to those who should not, go into our present high schools so as to inculcate in them principles of good citizenship and of economic understanding. England prepared to do this recently in the Act of August 1918, the most comprehensive educational legislation ever enacted at one time by any nation.

As a major part of this program England is developing compul-

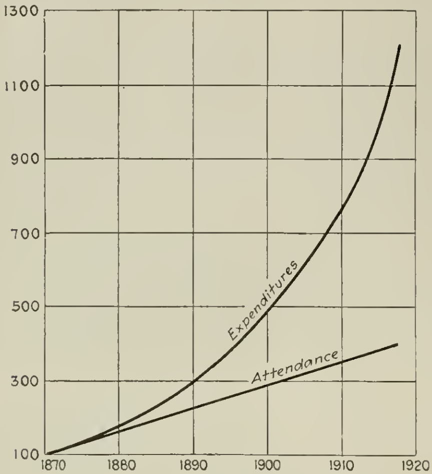

Fig. 2 School Attendance and Expenditures

Trend of average daily attendance and expenditures in public schools in the U. S. from 1870 to 1918 in percentages of the figures of 1870—W. R. Burgess, Russell Sage Foundation.

sory continuation schools for all workers under 18, and similar schools for adults up to instruction of college grade for labor leaders and others. Educators commonly agree that this training can be given in the grades. Remarkable success is secured from informal, well-directed instruction in these subjects in our army training stations, noticeably at Camp Grant near Chicago with enlisted men, including the illiterates.

The Mounting Cost of School Facilities

Not satisfied with the results of public education, America is resorting to her old makeshift, increased money expenditures, as indicated in Fig. 2 which starts with 1870 as 100 per cent and shows the relative increase in expenditures to the increase in hours of school attendance in the succeeding decades. In 1880 the two lines are not far apart. For increased expenditures we got proportional returns. In the decade 1880–90 the line of expenditures rises more than twice as fast as that of attendance. In the next decade over four times faster. In the next decade, long before the war, seven or more times faster, while in 1914, still prewar, the expenditure line has gone into the clouds with little improvement in total schooling received. A few years ago we spent $400,000,000 for public schools; last year $750,000,000; this year about $1,000-000,000; and the retiring Federal Commissioner of Education says we should spend $3,400,000,000 all told, which I judge includes some quarter of a billion for colleges. And he has substantially no suggestion for a change in the old policy of "go to college, or go to the devil."

Having exhausted the means of increasing school funds by the present methods of taxation, our school people are seeking new methods, new state and federal appropriations, and new powers to school boards enabling them to levy taxes independently and without regard to other local needs. Must not industry and the citizenship at large seriously consider where additional income is to come from, and see how far present expenditures can be made to yield better returns? Let us try for economy and improvement and not for increased levies only. Let us remember that not over 30 per cent of American youth have the natural qualification that permit them to complete a high-school course; that the mortality in the high schools supports this finding, half or more dropping out at the end of the first and second years. Let us develop collateral facilities equivalent to high schools at a fraction of the per capita cost and more effective for certain types than the present high school which educators declare to be still in the experimental stage—to be cherished but supplemented and modified.

What is the solution? The following suggestions have been approved in their general features by all prominent educators to whom they have been submitted;

I Elementary schools must be made more effective with the best possible instruction in citizenship and economics for every child before he leaves, and afterward in the continuation schools which have recently been established in 25 states, but very poorly developed. It is said that most of the instruction in the seventh and eighth grades is repetitional and waste, and can be replaced with citizenship and economics for those who go to work early, with a year saved to those who will study them in high school and college.

The Need for a Longer School Year

2 There must be more schooling per pupil per year. One-fourth of all enrolled pupils on the average are absent each school year, due to lax attendance and public indifference. Mr. Leonard Ayres says we have "the shortest school day, the shortest school week and the shortest school year of any first class nation in the world." See Fig. 3.

And what is all this for? For the child, who, as shown in the seventh bar, gets only an average of 605 hours of schooling per year, a year of 4500 waking hours, allowing ten hours for sleep. Remembering that 85 per cent of the children in our cities do not go to the seashore or the country in vacation time, but stay in the

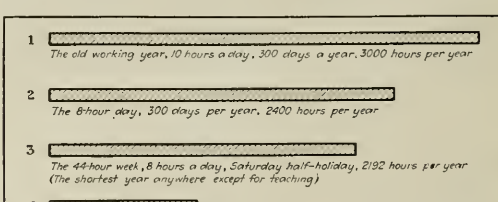

Fig. 3 What is a Year's Work for a Healthy Adult?

Bars 5 and 6 show only the fixed school hours. In addition, many high-school teachers in good schools average about two preparatory hours daily. Little outside work is commonly done by elementary-grade teachers.

city streets, and that almost all leave school at 14 or 15 years of age with a sixth-grade education or worse, it is a sin of the first magnitude that they are not given all the education they can take rightly each day and year. With book learning they should have training in health, the use of leisure time and regulated play, to make them sturdy, masterful little citizens measurably ready for life's cares and opportunities.

With open minds the school authorities must find for themselves what hours in each situation a teacher should work and require no less. Some educators approve of Amarillo, Texas, which recently employed one-third less than her usual number of teachers and increased the school year to 46 weeks; with 50 per cent in-

crease in teachers' salaries, but no increase in the total salary budget. The Federal Commissioner of Education inclines toward a six- or seven-hour school day and a 46-week compulsory school year. Our long summer vacation is said to be a relic of agricultural days when all children helped to raise the crops.

3 Teachers' salaries must be carefully determined that they be commensurate with those paid in other comparable occupations, and that rating and promotion be dependent not upon period of service only, as now, but also upon personal and professional and qualifications. There is a spirit of rebellion on the part of many because merit counts for so little, and consequently there is less inclination than heretofore for superior people to enter the profession.

Results of Adult Education Shown in Increased Industrial Efficiency

4 Facilities for adult education must be immeasurably extended. Education must not stop with the 14th year, the 16th year or any other year. As in some other countries there must be provision in day and night and part-time schools, in factories and elsewhere, for every one of whatever age who desires to enlarge his understanding as a citizen or to improve his economic condition. The extent to which this can be done has been demonstrated and shown to be profitable to employers as well as workers. The chart of Fig. 4 was prepared by one of the best production experts in America and published by the Federal Department of Labor. It presents a cross-section of American industry. It is a composite of several charts, some by Mr. H. L. Gantt, and includes such different types of production as power tools in a great factory of international reputation and the making of brushes, all showing substantially the same condition.

It shows all these workers averaging only 46 per cent efficient, with 59 per cent of them 38 per cent efficient. Post-war charts are similar but the percentages somewhat better. The wonder is, as has been often disclosed, that many of the workers in the 59

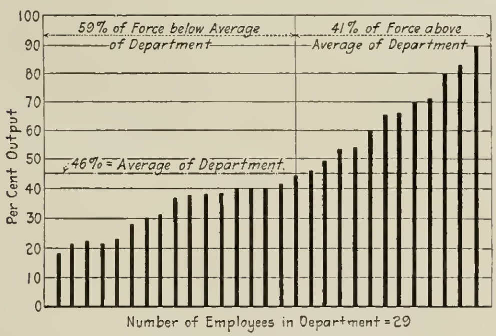

Fig. 4 Relative Efficiency of a Typical Factory Group

per cent group are as bright as the average in the 41 per cent of the best workers. They were put to work with no one to show them how. Those who, after proof in the best factories in America, have declared that the production of many workers can be doubled, have been criticized as exaggerating; but this chart shows how easy it may be to train an intelligent worker, man or woman, who is 38 per cent efficient, to be 75 per cent efficient. France by a general order required every considerable factory during the war to introduce these training departments; England also, but by clauses in her war contracts. If they increase production 20 per cent, which is easy, they effect a saving of $1,000,000,000 in payrolls, in wholesale prices of $2,000,000,000 and to the consumers $3,000,000,000. The aid to foreign trade with its keen competition is evident from this economy. But the greater accomplishment lies in the heightened intelligence, the happiness and the improved social attitude of the workers thus lifted in self-respect and capacity. What applies to factory workers in all these ways applies to all others.

The middle-aged man in a factory noted for its efficiency, whose production was increased 93.7 per cent by three weeks in the training department as shown in Fig. 5, looked upon his instructor as the best friend he ever had. He had been unable to support his family properly on his former earnings and considered himself a failure until so trained.

One of the largest producers of fine hardware in America tested the value of their training by the upgrading process in their special training room by comparing two men originally of equal capacity. The first man made no improvement in the 23 days of observation, while the other man doubled his production after 21 days of intensive instruction at absurdly little cost because the instructor was caring for other men at the same time.

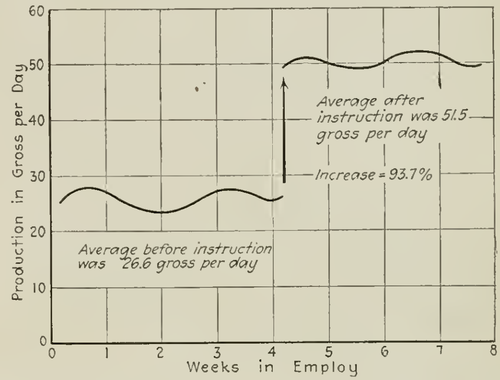

Fig. 5 Increasing Daily Production by Proper Training Methods

Fig. 6 shows how a group of 43 women long employed in one department increased their production 152 per cent in three weeks in the training department. In this case the training department was made a laboratory on methods, i.e., the methods of operation were improved at the same time as the skill of the operatives. As should always be the case, the teacher was a production expert who could also instruct effectively, giving him the twofold qualifications required in the trainer for production.

Fig. 7 shows, in the solid line, how a group of 50 women on power sewing machines were brought to full production in five weeks as against the 10 weeks (dotted line) required by old methods.

Apprenticeship Does Not Solve the Problem

We have greatly misunderstood apprenticeship in respect to its general applicability. It is desirable for the development of leaders who will cease to be wage earners as soon as trained. It is for one in a hundred. In three American factories famous for their highly developed apprenticeship courses it averages one in ninety. Most of our workers are doing work impossible of apprenticeship instruction of the old sort. The factory training department when rightly developed with what I call "intermittent apprenticeship" offers a substitute. A distinguished member of your association searches constantly throughout his force for average and superior men who want to advance, trains them for one limited field after another in his training departments and in regular shop work, and gradually lifts them higher and higher at good wages at almost negligible cost. He thus fills his best positions from the ranks, his master mechanic being of this class. The effect of this method upon the morale of the shop is evident.

To appreciate modern requirements and opportunities for trade training we must free our minds of traditional beliefs regarding apprenticeship. The so-called "halcyon days of apprenticeship" never were. There were halcyon days of guild monopoly with fathers paying large sums for their sons' indenture in these trades and their subsequent enjoyment of monopoly privileges, and there were apprenticeships of lesser value. I have diligently searched the authorities and, strange as it may seem, I cannot find that there ever was a time in England, the cradle of apprenticeship, when men entered apprenticeship much more readily than now because inspired by a desire to master a trade.

All through the middle ages from about 1261, the earliest mention of apprenticeship, to 1700, the time of its rapid decline, it was a

penal offense in England for any one except the eldest son of a master who "inherited apprenticeship," to buy or sell merchandise or to create any article embodying skill, except after apprenticeship which began anywhere from the eight to the seventeenth year, and ended about the twenty-fourth year. In about 1700, however, after two centuries of what we may call the "boot-legging" of those days, when men had persisted in acquiring skill in hidden places, in farm houses, "in aleys & upon steyers, and houses in corners," and in selling their products covertly, until finally the right to exercise one's faculties freely in production had come to be recognized, apprenticeship rapidly and greatly declined. Incidentally, it may be noted that during the long apprenticeship period of those days, little of mathematics or other book learning was taught and there was complaint as in our days that so far as the acquirement of skill was concerned the apprenticeship period might have been much shorter. It was made long that production might be cheaper.

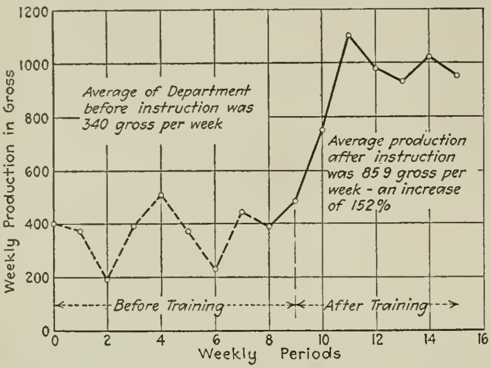

Fig. 6 Increasing Production of a Department by Correct Training Methods

During all these centuries England, by fixed policy and legislation, made low wages and this sort of apprenticeship the basis of her foreign trade and her commercial prosperity. She made herself supreme in skill and commerce, but her workmen paid the price.

It will comfort and inspire some of us to know that we need not attempt broadly and generally "to revive apprenticeship" by a return to the past, and that we have developed in considerable measure our own better way as shown in many factories, large and small.

Continuation Schools

The compulsory continuation schools now in operation in about 28 states are a modern substitute for the initial years of ancient apprenticeship. Where best developed, as in Boston and Milwaukee they are, with such extensions as will come naturally, the least expensive and most effective agency for the education of that 70 per cent of all our children who cannot or will not continue in the regular schools and have been entering the occupations at the rate of over 1,000,000 a year, unfitted therefor and without hope educationally.

Vocational education is essentially different from general education. The aim is vocation and education. The aim being different, the administration and methods must be different. Having, however, no system of vocational education in the United States we commonly think of it as something to be tacked on to the existing system.

Vocational schools, including continuation schools, must be directed and controlled by boards or committees representative of the vocations to be taught. Not because these representatives are better or worse than others; but because there are men in the vocations of as broad social vision and sound judgment as elsewhere, and because only men who have spent their lives successfully in the occupations know what the requirements are and can wisely select experts to meet these requirements.

The aim in vocational schools is production, the mastery of some one calling that leads ever upwards to higher places. Production is not merely the operation o˘ a machine and the making of things. It includes knowledge of the latest scientific methods as well as accuracy and speed. The Racine, Bridgeport and New Haven schools make commercial products for the market with the approval of labor leaders and all others. So do other good schools.

In Racine and Bridgeport the so-called "high-school manual training" is merged in the continuation and apprentice schools, thereby improving qualities, giving the favored high-school children desirable contact under superior conditions with their less fortunate fellows and saving the cost of separate high-school equipment and operation.

All-day vocational schools should operate 8 hours per day with Saturday half-holiday and 46 or 48 weeks per year, thus giving their working children, whose parents think they can ill afford to lose their children's time, the same hours they would have if in employment. This gives 10 per cent more hours of schooling in two years than the ordinary high school gives in four years, and gives a trade in addition.

5 Continuing the consideration of improvements, we may require, as a group of educators recently declared, that taxation be better safeguarded "to the end that a dollar's worth of education is received for every dollar spent."

The Training of Teachers

6 There must be great improvement in the quality and amount of teacher training in normal schools and in continuation and extension classes. Says the Commission on National Program of the National Education Association:

> The majority of the 600,000 teachers of the public schools represent in general a low level of maturity, general education and professional preparation.
>
> Of the twenty million boys and girls in our public schools today, it may be conservatively estimated that—
>
> 1,000,000 are being taught by teachers whose education has been limited to seven or eight years in the elementary schools;
>
> 7,000,000 are being taught by teachers who are scarcely more than boys and girls themselves;
>
> 10,000,000 are being taught by teachers who have had no special preparation for their work and whose general education is quite inadequate.

Support of Best Educational Leadership Essential

7 As a condition precedent to these attainments there must be an intelligent support of the best educational leadership, of which America has much that is as good as anywhere in the world. Also in the hundreds of thousands of devoted, aspiring members of the rank and file is a potential leadership hungry for opportunity.

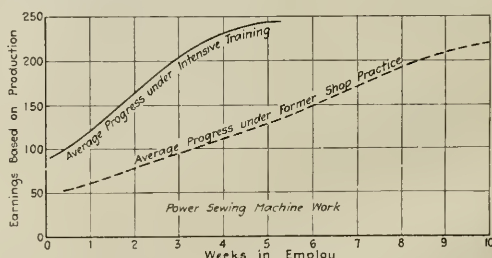

Fig. 7 Showing Saving in Time Effected by Intensive Training in Attaining Full Production

Collateral to this support of professional leadership must be developed a lay leadership, not more devoted nor high-minded than most of the present leadership, but thoroughly informed and therefore courageous; not getting in the way of the professional; not, as frequently now and to as bad effect, unintelligently supporting the wrong type of professional leadership, selected from personal appearance, political or other pressure, on letters of recommendation the general value of which none know better than employers.

Public education is not alone a professional matter. Education must be linked with life continuously and the forces of society should unite with the professional forces of education for a joint accomplishment. To this end there should be a central agency or clearing house for the collection and dissemination of facts in the

(Continued on page 550)

The National Metal Trades Association and Industrial Education

An Outline of Its Activities in the Training of New Workers, with the Opinions of Its Committee on Industrial Education Regarding Apprenticeship, Trade and Continuation Schools, Instruction by Foremen, Training in Plant, and Vestibule Schools

By HAROLD C. SMITH,[1] CHICAGO, ILL.

REALIZING the need for national concerted action in handling labor problems with which they were constantly confronted, a small group of manufacturers engaged in the metal trades industry, in the spring of 1899, formed an organization for this purpose. After twenty-two years of steady growth this organization, the National Metal Trades Association, stands out preëminently for fair dealing, strength, and efficiency. Its primary object, as tersely stated in its constitution, is "to secure and preserve equitable conditions in the workshops of its members for the protection of both employer and employee."

The fact that our country has occupied for so many years a leading position as a world commercial power has been due in a large measure to its unrestricted productive facilities afforded by the maintenance of American principles. Realizing this, the organization adopted early in its career as a vital policy in dealings between its members and their employees, the open-shop, or American Plan, principle.

In addition to being a stanch advocate of the open-shop principle as the only sound basis in dealings between employer and employee, the Association has also been mindful of the necessity for, and the far-reaching benefits incident to, other constructive activities. Consequently its field has become widened from time to time until now it is a potent factor in the furtherance of industrial training, safety, sanitation, Americanization, and kindred subjects. It actively coöperates with other national organizations of a constructive character, and is affiliated with the National Industrial Conference Board, a federation of national associations of manufacturers in the principal branches of American industry, which it aided in organizing.

For a number of years the Association has endeavored to point out to its members the necessity for training in industry and the importance of their assuming an active part in this work by the establishment of training units in their own plants and by coöperating with both public and private institutions organized for this purpose, realizing that this question will have a far-reaching effect upon the future of our industries.

Clearly nothing will tend more to the stabilization of labor conditions than an adequate supply of competent workers, the need for which until a comparatively recent time has been most keenly felt, and a shortage of which exists even today for normal production. From the worker's point of view training offers an opportunity to increase his efficiency and thereby greatly enhance his earning capacity.

A Brief Survey of the Educational Work of the Association

One of the Association's early efforts in educational work was the equipping with machinery certain buildings in the Winona Technical Institute, of Indianapolis, and the furnishing of scholarships, worth $100 each, for prospective students, the contributions of equipment and scholarships being made by individual members of the Association to the Institute. Later the Association, in conjunction with the Indianapolis members, voted financial support to the Institute for the maintenance of a Metal Trades Department, and appointed a committee to coöperate with the officers of the Institution in the management of that department. Subsequently, when the school system of Indianapolis took over the Institute and started the present Arsenal Technical High Schools, the equipment was given to the "School City," from which nucleus its present extensive system of shops for vocational and technical education has grown.

In coöperation with the University of Cincinnati, under Prof. Herman Schneider, members of the National Metal Trades Association opened their shops in 1906 to the students in the University's "Coöperative Course in Engineering," with the result that young men there are now getting a practical and technical training which was impossible under the old order.

Realizing the spread of industrial and vocational education and appreciating the work of the National Association for the Promotion of Industrial Education, the National Metal Trades Association, at its annual convention in 1911, made an appropriation to be used at the discretion of its Administrative Council for advancing the work undertaken by the former. Similar contributions were again made in 1914 and 1915. The passage of the Smith-Hughes Bill, granting federal aid for vocational education, it is believed was largely due to the efforts of that organization, aided by individuals and associations.

Immediately upon its appointment in the summer of 1918, in order to meet the serious labor shortage created by the war, the Association's Committee on Industrial Education entered upon a plan which had as its object the breaking in of unskilled workers and increasing the efficiency of those already in industry. As the result of a conference with Mr. H. E. Miles, Chairman of the Section on Industrial Training for the War Emergency, Advisory Commission, Council of National Defense, Washington, D. C., it was decided to make a study of the so-called "vestibule schools," which had for their object practically the plan just outlined, i.e., the instructing of new help and upgrading those already in the plants.

Accordingly, the Committee began its activities by visiting Cincinnati and Dayton during the month of September 1918, and plans were made to inspect plants in the East that were operating similar schools. While the signing of the armistice seemed for the moment to have removed the urgent necessity for this particular kind of intensive training, it soon became evident that industry could not afford to ignore the continued need for industrial training in the competitive days of peace. The Committee was so strongly of this opinion that, following a tour of inspection of a number of plants in Worcester, New Haven, Bridgeport, Stamford and Buffalo, it unanimously recommended to the Executive Committee of the Association the employment of a man especially qualified to carry on this work, whose sole duty would be to visit each individual member of the Association for the purpose of making a study of the plant called upon and offering recommendations based upon such inspection. This recommendation was adopted by the Executive Committee, in July 1919, and after careful consideration, Mr. Philip C. Milter was selected for the position.

Various Plans Employed in the Training of Workers

As a result of its studies the Committee has found that the training of workers is now being carried on under five general plans, each of which has its place in industry; and the Association recommends each and all of them to its members, depending upon the special case under investigation. These five plans may be designated as follows:

1. Apprenticeship
2. Trade and Continuation Schools
3. Instruction by Foreman
4. Special Training in Plant
5. Vestibule Schools.

[1] Illinois Tool Works; Chairman of Committee on Industrial Education, National Metal Trades Association. Mem. Am.Soc.M.E.

Paper presented at the Spring Meeting, Chicago, May 23 to 26, 1921, of The American Society of Mechanical Engineers. Slightly abridged. All papers are subject to revision.

Apprenticeship is particularly designed to take care of young men who wish to learn a trade in all of its branches, but is not generally adaptable to the instruction and upgrading of unskilled workers. The Committee feels that while there has been a lessening interest in apprenticeship as the result of conditions brought about by the war, this was nevertheless also due in a large measure to the unattractive conditions of the indentures. It hopes, therefore, to develop during the coming year some plan which it can recommend to the Association that will be sufficiently attractive to boys and the better grade of young men to hold them throughout the full course. Too much emphasis cannot be laid upon the desirability of each company's training apprentices in proportion to the needs of the industry, as regards growth and labor turnover.

Trade and Continuation Schools have for their object the manual and technical training of boys and young men in a particular craft or trade which they may select. By this form of education the boy is able to earn money throughout his school course, and if mechanically inclined obtain an education, whereas without such an opportunity many of them would be compelled to quit school entirely. This form of education is carried on in a number of cities, notably in Cincinnati, Ohio, and in Fitchburg, Mass. It has a further advantage in that it requires no additional expenditure or teaching force, with the exception of one supervisor to see that the industries and the public schools properly coöperate. Compulsory attendance at continuation schools by permit workers has also made rapid strides, twenty-five states now having legislation making education and training for these young people mandatory. The Committee recommends this form of education as being most desirable and most earnestly asks the interest of engineers and manufacturers in such schools where it is in existence, in order that they may be made most practicable and kept free from politics. There is a possible objection to the trade and continuation schools as the Committee sees it, and that is, they cannot be expected, no matter how efficient, to give to the minds of the workers that touch of confidence in the good intentions of a particular corporation in the same way that it can be given by the representatives of the plant itself, provided those who govern industry can be awakened to their duties.

This is the system most universally employed and it consists of putting the workmen directly into the department and under the supervision of the foreman in charge, who is entirely responsible for their success or failure.

The Committee found that the particular objection to this method was that the foreman, being responsible for the success of his department, in a great many instances had neither the time nor the patience to properly instruct the worker, nor in many cases the ability to impart his own knowledge.

There is also the possibility that prejudice on the part of the foreman may prevent him from properly instructing the worker in the performance of the required operations, the result being a lack of efficiency, causing a loss to both the employer and worker.

While the Committee admits that poor foremanship brings about many industrial faults, yet it does not believe that the foreman should be charged with conditions where the employers themselves have taken no definite steps to train him as to his particular duties. Foremen can be taught the fundamental principles of foremanship and department management from books and by teachers who are not themselves owners of industries, but, after all, the real policies that the foreman should live up to must be laid down for him by the manager of the plant in which he works.

Hitherto the foremen have had to build up their own policies from hearsay, deduction, or actual experience with each case as it came up. Different foremen translate management policies thus acquired in different ways, which means that the quality of foremanship varies from one department to another in a given plant. In the author's opinion, the only way a corporation can obtain a uniform dispensation of justice to its workers is for the management to see to it that its foremen are taught the policies of the corporation directly by the management or through authorized agents.

The proper course of instruction to the foreman should, in the opinion of the Committee, include:

1 The policies of the company as interpreted by its officers
2 The teaching of sound economic principles and their effect upon industry
3 The proper methods of manufacture
4 Proper instruction as to the best method to impart the above above knowledge to the workers under their supervision.

Special Training in Plant. This system, which consists of training in the department by a general instructor, has some of the advantages of the vestibule school and, it is believed, is preferable to instruction by foremen. It is particularly applicable in shops whose equipment consists mostly of large tools which cannot be isolated, and removes some of the objectionable features of training by foremen.

The Vestibule School. This plan came into prominence during the war. As the name implies, it is intended as the worker's entrance to the factory; and while by no means supplanting apprenticeship, is adaptable in some form to almost all shops, and, properly managed, goes far toward relieving the shortage of skilled labor. It has been applied very successfully to the intensive training of workers for repetition work, and has also been used to train specialists such as operators of particular types of machine tools. To this school should be sent all accepted applicants, where their fitness or unfitness is readily determined. The length of time spent in the school depends upon the skill possessed at the start, the aptness of the student, and the character of the work he is to be taught. The Committee found in the schools visited that the training time varied from three days to three months.

Since entering the service of the National Metal Trades Association, Mr. Molter has worked in eight districts, visited 130 shops, and has made a large number of formal surveys and a greater number of informal recommendations. His reports show that almost without exception the members visited have displayed much interest, and the Committee feels that worth-while work has been done. As a result of Mr. Molter's visits, a number of companies have installed definite training methods, while a greater number have signified their intention of doing so as soon as conditions warrant. In addition thereto it has been very gratifying to learn that a number of members, whose interest in industrial education has been stimulated by the publicity work carried on by the Association, have, of their own volition, set up complete training shops.

It is worthy of mention that the National Metal Trades Association is the only country-wide organization in the United States that is prepared to undertake the work of industrial training in a practical way, it being the opinion of its officers that the duty of furnishing industrial education to our young people will devolve sooner or later upon industry itself.

Among the reasons for believing that industry must assume much of the task of education is the fact that a great number of young people leave school at the earliest "permit age" in order to go to work. It is unnecessary to discuss the reasons for this phenomenon, but the facts as shown in the 1917 report of the Commissioner of Education show that out of a total school population between the ages of 10 and 14 of 9,939,532, only 145,891 or 1.47 per cent are not in school, while in the next group, ranging from 15 to 17 years of age and 5,823,160 in number, 2,463,458 or 42.30 per cent are not in school. The next group, ranging from 18 to 20, shows 82.87 per cent out, and of those from 21 to 24, 95.17 per cent no longer attend any sort of school.

Another table in this same report shows that the group which started school in the first grade in 1906 dropped from 4,066,091 at that time to 1,244,098 in the eighth grade, and of these only 629,432 entered high school in 1914–15, and it is estimated that only 117 out of each 1000 entering the first grade in 1906–07 would be graduated from the high school in 1918. Need we elaborate on this condition to show that we have a duty to perform?

Findings of Committee on Existing Industrial Conditions

As a result of its studies during the year, the Committee on Industrial Education of the National Metal Trades reported to the annual convention in April that they found the following conditions to exist:

1 A shortage of efficient workers for normal production
2 Too few companies train workers

(Continued on page 550)

Future Power Development in the Middle West

By C. W. Place,[1] Chicago, Ill.

In this paper the author outlines a system in which it is proposed that the fairly efficient steam power plants in the 100-odd cities of over 25,000 population in the 14 middle-western states be interconnected, not by heavy high-voltage lines, but by lines running from each which will pick up the small-town and village load to the point where its next larger neighbor will take its share; hydroelectric plants are to be installed on the streams near the towns and villages, each with a small pondage; the steam stations are to carry the steady continuous load above the maximum stream flow, the hydroelectric plants automatically coming on to carry the peaks. On the off-peak period the hydroelectric plants will restore the pondage and carry local load. The quickness with which the latter can get on the line (12 to 30 seconds) will enable the steam stations always to work at maximum efficiency. The advantages of the system are pointed out in the paper, as well as the procedure necessary to bring about its development.

Up TO a certain point in the growth of a country or under abnormal conditions, the growth and development are the important things: the means to the end or the cost are not of great consequence. Economy and the conservation of natural resources cannot be allowed to interfere with this early expansion, but there is nevertheless some stage of development and concentration of population where early methods must be changed.

Present Sources of Power in the Middle West

At present the sources of power for the supply of light, heat and energy for the mechanical operations necessary for the life and continued development of the Middle West are coal-, oil-, and gas-fired steam equipment, internal-combustion and heat engines, and water-driven equipment. Wind and solar-heat sources need not be considered.

Fig. 1 is a map of the Middle West showing the coal fields it draws from, as well as the rivers and larger streams. Table 1 gives the coal production of this region according to Government estimates for the period 1917–1920, and Table 2 data on the potential and developed water of the fourteen states it includes. Table 3 shows the oil production of the United States in 1920, that of the Middle West being 15 per cent of the total.

It will be noticed in Fig. 1 that the coal fields are not located conveniently as regards water supply for condensing purposes and are not particularly convenient to the load concentrations as at present arranged. A recent news report indicates that the Federal investigators on power conditions of the Atlantic Coast states have concluded that the solution of the problem does not lie in enormous production at the mines on account of condensing-water conditions. On the basis of our conditions and economical production, every 100,000 kw. produced in a day would probably require 380 million gallons of water, or a flow corresponding to 588 sec-ft., for condensing purposes. It would therefore seem that the demand for power in the Middle West cannot be taken care of at the mines as these are not situated near streams of the proper size. The rivers and streams are in better relation to the load, as the cities and towns have grown up along these streams.

Power Potentialities of the Rivers and Streams

The production of power thus far by steam has been practically always at the load concentration. A start has been made transmitting from steam stations to less heavy load centers. A moving of load to cheap power has been successful in a number of cases, but this has caused unnatural conditions in other respects and has not necessarily been for the greatest good of the country as a whole. We have no great sources of hydraulic power conveniently available which can be profitably developed at present money rates and material costs. We must therefore lay our plans on our real conditions and not on some imaginary combination as regards power supply or regrouping the load arrangement. Large blocks of power have been developed at centers of load by large steam stations. These large centers are, however, not close together but each has its tributary country with low load density. This

Fig. 1 Map of the Middle West, Showing its Rivers and Larger Streams and the Location of its Coal Fields (Shaded Areas)

territory is made up of towns and villages surrounded by farming country drained by innumerable streams.

Most of these streams have comparatively low banks, have bottom lands which are good farming land and have extreme flood and low-water periods. As one travels along these streams any number of small dams may be seen that are either partly washed out or are still serving to drive some mill and making a more or less efficient use of the water going down the stream. From his observations the author would say that these streams would be

[1] General Electric Company.

Paper presented at the Spring Meeting, Chicago, May 23 to 26, 1921, of The American Society of Mechanical Engineers. Slightly abridged. All papers are subject to revision.

able to supply the necessary power for all the towns and villages near them of 25,000 population or less; that during a good part of the year they could assist even in these towns during the peak if properly connected and manipulated. In these fourteen central states there are but 102 cities of over 25,000 people, and cities of this size have already established quite efficient steam plants.

Proposed Interconnected System of City Steam Plants and Village Hydroelectric Plants

Suppose now that the power houses of all these 102 cities were connected together, not by heavy high-voltage lines, but by lines running from each which would pick up the small-town and village load up to the point where its next large neighbor would take its share, and that the streams near these towns and villages had hydroelectric stations of a size proportionate to the size of their respective streams. These 102 steam stations must work on a fair load to get their best efficiency both from a steam-economy and a maintenance basis, and when the units are operating at good efficiency a sudden increase in load cannot be handled properly until other units are brought on and steam conditions have been restored. During this period of adjustment the voltage goes down and the frequency droops, and would droop more if the voltage were brought back to normal.

During 1920 about thirteen million barrels of crude oil were used by public utilities for power production. Of this California and Texas used 8,500,000 bbl. and Missouri and Kansas the greater share of the remainder. Crude oil is therefore of relatively little importance as regards the total power requirements.

Due to these conditions extra machines are now carried either under part load, or ready to put on at once. Suppose the interconnection mentioned above has now been made, and a goodly number of these hydraulic stations installed. These hydraulic stations are large enough to take a little more than the average stream flow, i.e., are overdeveloped. Each has a small pondage and is automatically controlled so that it will come on on a drop of frequency of the system and in sequence with other plants, depending on the proportion of its working head available at the instant. That is, the plant with the best water conditions will get on the line the quickest. It will drop off the line on a decrease of its water supply or a dropping off of load. The steam stations are operating efficiently and have a sudden increase in load.

These various hydraulic stations are operating, using up the natural stream flow and sending but a very small proportion of their load toward the city. With the droop in frequency the several water-wheel generators installed for the flow above the average begin to come in and to draw on the ponds. Enough come in to bring the frequency back to normal. In the meantime the steam stations are back to normal. The operators have not let the voltage stay down to save the speed, but have restored it at once and the service has been maintained. With this automatically started reserve there is an opportunity to decide whether the load is going to continue, and if so, to get on extra boilers and machines. It is known that the hydraulic helpers are going to begin to drop out as they exhaust their pondage, so the steam operation can be governed accordingly.

Again, suppose that each of these streams had the low swampy ground and the willow thickets made into ponds even where there was insufficient head for power development, which could release when the ponds with hydroelectric stations were drawn down by this sudden drain, and close when the station pond was restored. This would mean perfect flood control for normal rises, and, by holding out the steam stations, very good control during extreme floods.

These smaller streams lead to the larger rivers and with an approach at flood control on the tributaries there would be a greater number of locations for hydroelectric development on a larger scale along these larger rivers, each to be controlled in the same way. Each development would help the flood conditions below and make feasible developments not now economically practical.

Very closely resembling this hypothetical case is the arrangement for taking care of the peak load of New York City suggested by F. O. Blackwell at a meeting of the New York Section of the American Society of Civil Engineers, February 9, 1921. Mr. Blackwell stated that water if pumped up to an area on the Palisades during the peak, would develop the peak power more economically than it could be done by any other method of reserve. He further stated that this is being done in several installations in Switzerland, the water being pumped into reservoirs when the load is light. Prof. R. A. Fessenden in April published an article suggesting that such storage be made underground, the hole being dug near the load.

Our conditions do not perhaps lend themselves to this arrangement as readily as the combination mentioned previously. There are, however, cases where these schemes would probably work out. Along certain parts of the Mississippi River there are high bluffs and in some places the land is not particularly good on top of the bluff. A transmission line along the bluff might obtain the reserve capacity in this manner if at the same time the pondage could act as a reserve reservoir for city filter beds or some such purpose. There are high valleys in the Ozarks where there is no natural large water supply and where the land is of little value which could act as such a reserve if properly arranged and if in conjunction with the natural water-power supply in the same region. This might even make some of the powers with greatest water fluctuations economically feasible.

As regards Chicago, there is quite a large reserve at the east in Lake Michigan. On the way to Lockport there are large areas of worked-out stone pits and ground where it might be possible to get short-time storage so that the drainage canal could be upon for such peak service without unduly drawing down the lake level. Excess capacity would have to be installed at Lockport.

The State deep-waterway project could be overdeveloped and operate along this line if properly connected and operated.

All this sounds highly imaginary, but it is being done on a small scale in Saline and Seward Counties, Nebraska, along the Big Blue River, with manually operated and automatic stations, except that as yet there is no steam reserve. This system is being extended by the addition of more stations, and from present indications the entire river will soon have increasingly larger stations installed, the dam of each being at the point where the ordinary backwater from the dam farther down the river runs out. Other systems are also doing something along this line.

Advantages of the Proposed System

Suppose this idea were carried to its ultimate conclusion. The steam station would then carry the steady continuous load above the minimum stream flow, and the hydraulic equipment would carry the peaks, and on off-peak periods restore the pondage and carry local load. The quickness with which the hydraulic stations can get on the line (12 to 30 seconds) will allow the steam stations to work always at maximum efficiency.

All of these developments must be made at a cost that will show

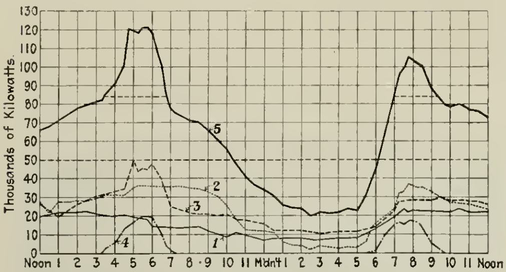

Fig. 2 Daily Load Curve of a City Having Steam and Water-Driven Power Supply for Lighting, Power and Railway Service

Curves	Kw. Peak	Kw-hr.	Load Factor, per cent
1—25-cycle steam generators..	24,000	362,150	62.8
2—60-cycle steam generators..	36,600	552,490	62.9
3—25-cycle hydroelectric generators............	50,000	528,000	44.0
4—Railway Co. steam generators	20,180	79,610	16.4
5—Total....................	121,500	1,522,250	52.5

a reasonable profit. In order to arrive at the correct profit, however, all the advantages must be weighed. A small automatic station tied to the line has a stabilizing effect on voltage which should be worth something. It should receive a credit equivalent to the transmission losses and another on the basis of the investment in coal storage of the steam station which it relieves; it should also receive some credit due to absence of labor trouble.

A multitude of these small stations will, by means of legitimate interconnections, do more actual work than the same installed capacity in one station. The small station made automatic can usually be installed on a much more satisfactory basis than the large plant. It can usually be financed locally, and a good share of the money will remain near the site. A large amount of land will not be taken out of production, so there will not be a large overhead, and the land taken will be of small value. If the development is forced beyond a certain point under middle-western conditions, this land becomes the most valuable corn land in that section, i.e., the second bottom land. The dam which before was an easy proposition on a more or less soft bottom, now becomes a difficult one, and the development will not show a profit. It is therefore necessary to multiply the number of stations instead of increasing the size if we wish to get total capacity. If these smaller stations are first installed it would seem that the larger streams could be used if developed on the same general plan and money made by the development.

Fig. 2 shows the daily load curve of a city having steam-and water-driven power supply, and having lighting, power and railway load served. If the water could be called to carry the sudden rise and the extreme of the peak it can be seen what an advantage it would be. It is evident that this could not be done with a single source of water power with any storage available in the river valley, but only with a number of such reserves acting for a territory rather than for one city.

What, now, are the things that we should do? In the opinion of the author—

1 The stream conditions and their possibilities should be studied with the above-described or some similar method of utilization in view.

2 Public opinion should be guided in the proper direction so that it will not obstruct such development.

3 Rivers which are technically navigable but are not really so should either be released or made navigable and the flow used for power development, and the engineer's influence should be used to bring this about.

4 In the permanent-highway-improvement campaign, influence should be used to have these permanent highways diverted from sites capable of future development or their natural ponds.

5 The relative importance of railway transportation and power development may change, so that any readjustments of railway roadbeds up river valleys should be along lines that will not interfere with the possible stream development. It may easily prove that the railway may be the first and most important benefactor in its electrification. Public sentiment might very easily assist in this.

6 Existing power sites in the form of mill dams should be developed and tied into the nearest transmission, and the possibilities in this direction should be investigated and taken advantage of in every locality.

7 The investing public should be instructed regarding developments in their vicinity. They should be shown that our water-power possibilities are not gold mines for the owners and are of little value if not tied in with existing systems; but that when they are so tied in they increase the value of the system and make its securities much better from the investment standpoint.

Germany Developing Water Power

Quite an extensive hydroelectric project is being undertaken in Germany in the development of the Neckar River. Capital requirements during the next few years are estimated at 950 million marks, while the total capital required for the completion of the scheme will amount to from 1900 to 2000 million marks.

While the ultimate object of the whole enterprise is the canalization of the Neckar and the linking of that river with the Danube, its immediate purpose should be seen in the harnessing of the Neckar and the generating of hydroelectric energy with a calculated output of 70,000 hp., equal to 300,000,000 to 400,000,000 kw-hr. The whole scheme represents a bold attempt to render large industrial districts in the south of Germany less dependent on outside coal supplies, and its success from a revenue-paying point of view will, in a measure, be linked with the future development of the South-German coal market and, above all, inland coal prices and coal taxes.

The entire project, covering the section of the Neckar from Mannheim to Plochingen—a distance of about 210 km.—provides for 25 to 28 dams. It is intended to start building operations at the five best-suited barrages without further loss of time and the first 700 million marks' worth of obligations will shortly be issued. Completion of the scheme in its present form will take from 10 to 13 years. Concessions have been granted for a period of 100 years.

Another big hydroelectric scheme is planned by the Prussian government in the form of a supplement to the state hydroelectric plants on the Weser and the Main, comprising four new plants to be erected on the Fulda at Cuxhaven, Freienhagen, Wahnhausen and Munden, of which only the Eder Valley power station is in operation as yet. Plants already erected and in course of construction on the Weser and Main will yield an aggregate of 66 million kilowatt-hours per year after completion, and the output of the projected Fulda plants is estimated at 69 million kilowatt-hours annually.—*Power*, July 26, 1921, p. 133.

Some Technical Problems in Aeronautics

Aluminum Cylinder Castings, Air-Cooled Airplane Engines, Airplane Carburetors and Radiators, Aerial Photography, Machine-Gun Synchronizers, etc., as Discussed on Occasion of A.S.M.E. and S.A.E. Joint Visit to McCook Field, May 21

IN connection with the joint visit of the Aeronautic Division of The American Society of Mechanical Engineers and the Socety of Automotive Engineers to the Air Service Station at McCook Field, May 21, a very interesting technical program was presented by the members of the Field's staff. Joseph A. Steinmetz, Chairman of the A.S.M.E. Aeronautic Division presided. Brief summaries of the eight papers read immediately follow.

Aluminum Cylinder Castings

DISCUSSING this subject, E. H. Dix stated that a satisfactory bond between the steel cylinder and the cast aluminum head was formed with either sherardized or tinned steel cylinders.

FIG. 1 BOND BETWEEN ALUMINUM CAP AND SHERARDIZED STEEL CYLINDER Unetched; Magnification × 200. A—Steel cylinder; B—Sherardized coating; C—Zinc-aluminum alloy; D—Copper-aluminum alloy.

Sherardizing was decided upon because of the higher melting point of zinc. A micrograph showing the bond is given in Fig. 1.

The problem of an alloy for valve-seat inserts and spark-plug bushings was solved by the adoption of a rolled phosphor bronze containing $3^1/_2$ per cent tin—chosen because its coefficient of expansion approximated that of aluminum.

The next step after these preliminary experiments was to make the actual casting. Fig. 2 shows the open mold with steel cylinder, cores, valve-seat inserts and spark-plug bushings in place. The job was made up using dry sand cores inside and outside. The method of gating is evident from the view of the cope. Three overflow risers were placed to allow for the pouring of metal through the mold.

Metal was poured through the mold so as to heat the cylinder and prevent the cracking of the aluminum casting if possible. However, the first casting showed a serious axial crack just over the steel ring. It was therefore decided to put a heating coil inside of the cylinder. This was done and a second casting poured. In this case, however, the cores were thoroughly heated before pouring, and the whole mold was placed in a core oven at 500 deg. fahr. immediately after pouring and allowed to anneal for a day and a half. This eliminated the cracking around the steel cylinder, but a crack developed in another place, that is, between two of the valve-seat inserts. It is believed that these difficulties can be overcome by slight changes in the method outlined, although preheating the mold and the subsequent annealing would make a rather expensive production job.

It has therefore been decided to endeavor to find an alloy which is less liable to crack than the one previously used which was 7 per cent copper, 1 per cent tin, and the remainder aluminum, this being recommended from the experience gained in England on a similar proposition. To guide in this selection, a hot-shortness test was devised. This consists in casting a test bar around steel lugs fixed 12 in. apart as shown in Fig. 3. The first three bars shown in this figure are aluminum alloys containing 8 per cent copper, 10 per cent copper, and 7 per cent copper + 1 per cent tin, respectively, and it will be seen that all cracked. The fourth bar is a silicon-aluminum alloy on which the Material Section is experimenting at this time. This bar showed no crack when cast in this manner. Arrangements are being made at the Bureau of Standards to have coefficient-of-expansion tests made on this alloy.

Mr. Dix pointed out that he had summarized very briefly a problem now of very vital interest to the Air Service and of which no more than the surface had been scratched, and he hoped by so

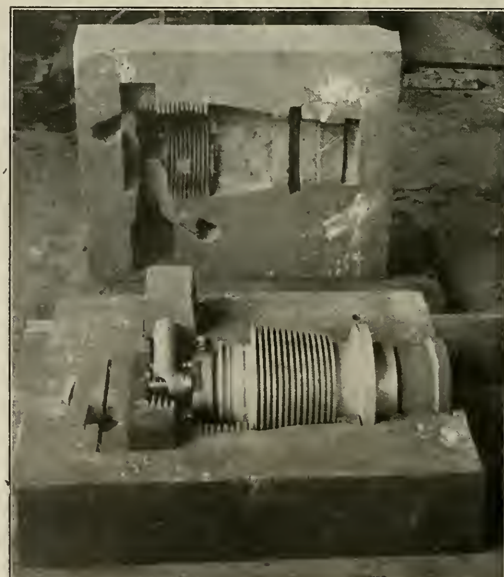

FIG. 2 MOLD FOR CASTING ALUMINUM HEAD ON STEEL CYLINDER OF AIR-COOLED AIRPLANE ENGINE. DRY SAND CORES USED INSIDE AND OUTSIDE

doing an interest might be stimulated among the engineers present which would result in valuable suggestions for future work at the Field in this connection.

Air-Cooled Airplane Engines

IN his treatment of this subject, S. D. Heron pointed out that the advantages of an air-cooled engine for military purposes were that it is less vulnerable to fire, freezing does not occur during long drives, and overheating due to a steep climb is temporary. The air-cooled engine however, has not reached the finality of design of the best water-cooled engines, although cylinders up to

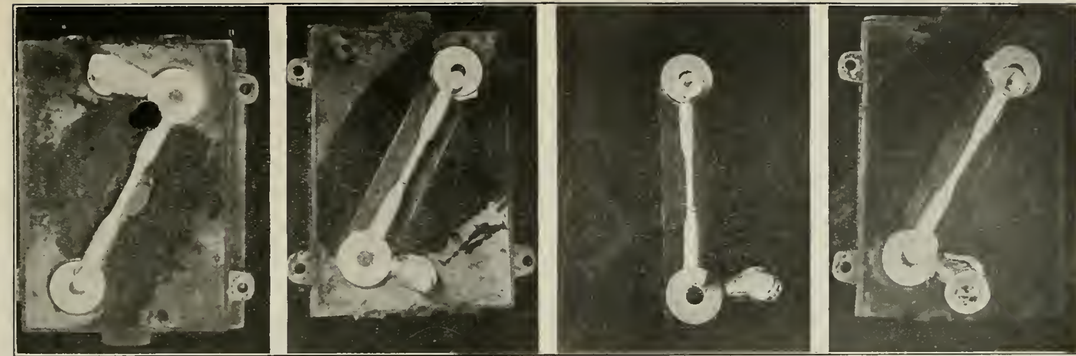

Fig. 3 Hot-Shortness Tests of Aluminum Alloys

150 cu. in. of swept volume have equaled the best water-cooled practice in power, brake mean effective pressure, and exhaust-valve reliability. Fuel economy with maximum power mixture is from 5 to 15 per cent less than in the best water-cooled engines. The advantages of the air-cooled engine have been shown in service when receiving a minimum of skilled attention. They have given good results in the Egyptian desert and in Mesopotamia.

In most designs of a cylinder for the radial engine, a compro-

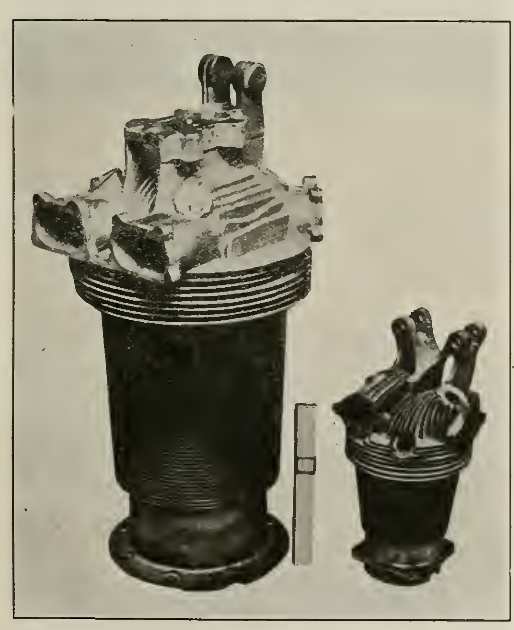

Fig. 4 Probably the Largest and Most Powerful Air-Cooled Airplane Cylinder Yet Made (8 in. Bore by 10 in. Stroke)
(Cylinder at the right is 4½ in. by 6 in.)

mise between cooling efficiency and proper valve operation is evident. The speaker pointed out that in the air-cooled cylinder cheapness and lightness have been overemphasized, with the result that cooling features have suffered. The resulting designs would not be tolerated in a high-class water-cooled motor.

As to V-engines, twelve-cylinder types up to 240 hp. have been constructed satisfactorily and have given good service. The valve operation of this type is complicated because of the location of the exhaust side of the cylinder relative to the air blast.

Dealing with the question of cylinder design, Mr. Heron described the results secured by the British with the spherical aluminum head cast or screwed to an integral fined steel barrel. He presented data from a number of tests of air-cooled engine cylinders which show that the highly efficient cylinder has not a low weight per cubic inch of swept volume. Fig. 4 shows probably the largest and most powerful air-cooled cylinder yet made—the R.A.E. 19 T., with 8 in. bore and 10 in. stroke and developing 129 b.hp. The cylinder on the right is a $4^1/_2$- by 6-in. R.A.E. 22 T.W.

Carburetors for Aircraft

THE carburetor problems of aircraft engines were outlined by C. Fayette Taylor in his remarks. A more simple type of carburetor can be utilized in airplanes than in automobiles, the open-tube type with some form of accelerating well being the most

Fig. 5 Airplane Models, Showing Systems of Camouflage for Upper Surfaces. Dark Areas are Models Covered with Standard Varnish

common. Most aircraft engines carry from two to six carburetors, which constitutes a problem in obtaining uniform adjustment and synchronization. This precludes the ordinary needle-valve fuel adjustment, and fixed fuel orifices are therefore the rule. The necessity for operating under extreme variations of temperature and pressure requires that the fuel-metering orifices must be large enough to take care of the highest density at which the engine will operate. A manual control is therefore provided.

Extreme variation from the horizontal position brings about a severe condition for the aircraft carburetor. This condition is met by carefully locating the float chamber in relation to the fuel nozzles amd metering orifices.

In order to reduce the fire hazard, the carburetor air intake must project outside the engine cowling. This means that the aircraft carburetor must take its air from a slip stream traveling from 100 to 200 m.p.h.

Airplane Camouflage

THE purpose of color camouflage for airplanes as stated by Gerald P. Young, is to break up the outline of the plane. The coloring of the upper surfaces is a combination of tan, blue green and mauve purple. The general scheme followed is to divide the surface into three irregular areas of large curving boundaries, applying these three colors both to the upper surface of the top wing and the upper surface of the lower wing. The same colors are brought back along the top of the fuselage and tail surfaces. The idea is to make the plane less visible when observed from above, and a tan section, blending with tan earth colors, causes it to become practically invisible, leaving only the darker colors which, being arranged irregularly, throw the eye off from the general outline of the plane and cause the observer to lose the plane in the background beneath.

This system is of value for planes left in the open at flying fields or when parked in the field at night, and also for concealing bombers flying at low altitudes and observed by pursuit planes from above.

The under surfaces of planes are camouflaged to give a light reflecting surface and the coloring scheme is burnished aluminum, light blue, light purple and white. This system makes it possible for an airplane regularly finished in dope and varnish having a light yellowish cast and visible at altitudes up to 17,000 ft., to become invisible at an altitude considerably under 10,000 ft.

Radio Communication

DEALING with this subject, O. E. Marvel described the characteristics of continuous wave transmission and the vacuum tube, the one thing that made the radio telephone possible. He explained that all airplanes radio sets are now designed for telephoning and continuous wave telegraphy. He emphasized the importance of radio communication, especially in military movements such as artillery fire control, infantry contact work and reconnoissance. He also emphasized the importance of wireless in direction finding—used during the war to locate enemy radio stations and to navigate aircraft.

Fig. 6 Airplane Model Against Sky Background, Showing Comparison of Standard Varnish with Camouflage Scheme

Airplane Radiators

LIEUT. Bayard Johnson spoke on the subject of airplane radiators. He pointed out the fundamental differences between the problems of radiators on an airplane and on an automobile engine, emphasizing the large quantity of water which must be forced through the airplane radiator and the need for unrestricted flow. The standard radiator core adopted by the Air Service is made of seamless round copper tubes with hexagonal ends. It gives small resistance to water flow, has no internal soldered joints, can be easily installed, is light and is most effective for air speeds of 80 miles per hour and over. In discussing the location of a radiator he emphasized the necessity for a support as free from vibration as possible. Comparing relative values of frontal, wing, landing-gear and side radiators, the advantages of the side radiator were shown, as they are protected from damage and have high air speeds available. Although the piping is long, it is accessible and warms the pilot hands. He also emphasized the need for accurate information as to the performance of different types of radiators and stated that the Engineering Division of the Air Service was progressing favorably in obtaining this information.

Aerial Photography

IN discussing aerial photography, Capt. G. W. Stevens described different types of films and plates and showed that film in rolls permitting 100 exposures, which does not require bulky, heavy magazines and is not subject to chipping or breakage, is more desirable for aerial photography. With suitable ray filters to eliminate haze it is possible to get good negatives from heights of three to four miles. A camera specially designed by Major Bagley of the Corps of Engineers has three lenses, making one vertical and two oblique negatives at the same time. At an elevation of 15,000 ft. it takes in an area 8 miles wide. With this mechanism artillery fire control can be carried into the enemy country with an error of but 200 ft. in 15 miles. The use of the camera in mapping was explained by the speaker, who showed a slide of a mosaic of the city of Rochester made up of 83 negatives.

The Influence Exerted by the Automobile on the Machine-Tool Industry[1]

A Group of Papers Dealing with the Changes Brought About by the Automobile in Machine-Tool Design, Construction and Operation, Together with a Discussion of the Fundamentals of Interchangeable Manufacture

The session of the Spring Meeting of The American Society of Mechanical Engineers held under the auspices of its Machine Shop Practice Division was devoted to a consideration of the influence of the automobile on machine-tool design and operation during the past decade, with special reference to gear cutting, lathe practice, and the stamping and forming of sheet metals; and to the subject of interchangeable manufacture. Five papers in all were presented, abstracts of which follow, together with a brief account of the ensuing discussion.

THE INFLUENCE OF THE AUTOMOBILE ON THE MACHINE-TOOL INDUSTRY IN GENERAL

By F. K. Hendrickson,[2] Worcester, Mass.

During the years 1910 to 1913 the automobile industry began to exert a great deal of pressure on machine-tool manufacture and design, and about this time several concerns found it necessary to make extensive and very expensive changes in their systems of production to meet the rapidly increasing demand for cars. To arrive at the best conclusions and in order to secure the most modern installations, they invited many of the best engineers and machine-tool manufacturers in the country into conference with them. Each individual piece was considered separately and at times in the presence of two or more representatives from different firms, with the result that highly specialized machines were rapidly developed.

A brief study of the developments in machine-tool building attributable to the demands of the automotive industry therefore seems desirable at this time, taking up in their order the following elements which go to make a successful machine:

1 Materials and their proper distribution
2 Precision and Specialization
3 Power
4 Manipulation
5 Speed
6 Lubrication
7 Safety Devices.

Materials. Every mechanic is fully aware of the extremely rigid construction which has been demanded, due to the ever-increasing strains to which machines are subjected. In addition to the extra weight thus entailed, materials of high tensile and torsional capacity have been substituted. A few examples will suffice to indicate the trend.

Lathe spindles originally 30- to 40-point carbon steel, are now made of 15- to 20-point steel, being carbonized and hardened to produce glass-hard surfaces. The diameters also have been greatly increased.

Lathe centers formerly quite small, unhardened and of low-grade tool steel, are considerably increased in size and hardened at the point on both head and tail stocks.

High-speed cutting tools generally supported in special rigid holders are replacing almost entirely carbon-steel lathe and planer tools, twist drills, reamers, milling cutters, taps and dies.

Babbitted journals or bearings are rapidly being replaced by the best-quality bronze metals, and the tendency is toward the application of ball bearings. Certain types of machines have already been forced to incorporate them on their main spindles and with success, which indicates that the same conditions will ultimately obtain in other machines.

Cast-iron gears for speed and feed changes have been discarded in favor of the hardened steel gears, except in a few machines where the speed changes are accomplished by the engagement of friction clutches, thereby permitting the gears themselves to remain constantly in mesh their full depth and width of tooth, and leiminating the shock that otherwise results.

Clash gears, either of the sliding or tumbler type, have proved absolute failures when made of cast iron or soft steel, but are satisfactory when made of the proper steel and subjected to suitable heat treatment.

In addition to producing gears of wear-resisting qualities, it has also been necessary to develop their efficiency and to produce much quieter running. To accomplish these conditions, several machines are today equipped with helical or herringbone gears to produce smooth action and silent running under high speed and strain. New forms of spur gears are also being developed which are claimed to successfully meet the requirements.

Precision and Specialization. Grinding machines have been brought to a high state of perfection and produce a truer and finer quality of work on all revolving and sliding parts much more rapidly than ever before. Closer limits and tolerances have been demanded, with the result that the one-time all-around mechanic has been replaced by the present specialized expert, in order to obtain the highest grade of precision in quantity.

Power. Along with the added strength and rigidity of the machines must necessarily be considered their power. The automotive industry has accomplished much in the direction of insisting that the drive shall be either of the geared or silent-chain type to prevent slippage, usually prevalent when machines are belt-driven. The individual motor installation has also come into common use, and at the same time the horsepower of the motor has been increased sufficiently to care for the extreme loads.

For example, a few years ago a 14-in. geared-head lathe was equipped with a $^3/_4$-hp. motor, while today the machine must be provided with a motor of 2 hp. at least and preferably 3 hp. This proportion may not be general for all classes of machines, but is a fair criterion of the present condition.

Manipulation. One of the very essential features demanded in present-day machines by the automotive industry is easy manipulation and the convenient location of the operating levers, handwheels and cranks. Speed- and feed-changing mechanisms must be located within easy reach of the operator and must not cause him any undue exertion or unnecessary delay.

Where there is a sufficient quantity of pieces and the parts lend themselves to magazine or hopper feed, these must be included in order to assist in the handling of work. If the parts are heavy or bulky, mechanical or electrical handling devices must be provided in order to secure high production.

Speed. Several years ago speed bosses were practically unknown, but with the advent of the automobile era has come this type of functional foreman and with him a demand for readily obtaining in a given machine the proper speed and feed for the work. To meet this ever-increasing demand machine-tool manufacturers have in general incorporated mechanical speed-change heads and quick-change gear boxes for feed variations in their machines. Motors of the variable-speed type are used when mechanical changes are not available.

It is interesting however, to note certain specific conditions which, although contrary to the general demands, have worked out in the most gratifying manner. During 1912 and 1913, in a well-established automobile plant in Detroit, the production of

[1] Abstracts of papers presented at the Spring Meeting, Chicago, May 23 to 26, 1921, of The American Society of Mechanical Engineers. All papers are subject to revision.

[2] Chief Engineer and Designer, Reed-Prentice Co., Mem. Am.Soc.M.E.

transmission parts was receiving the most careful consideration as to the best method to adopt to materially increase their already heavy production. It was finally decided to adopt a single-purpose lathe having one speed and one feed, properly calculated to obtain a maximum production for each individual piece.

The Reed-Prentice Company, of Worcester, Mass., placed the first of these single-process automatic lathes into actual operation, and much to the satisfaction of all concerned the production was increased from 25 to 50 per cent. Additional machines of the same type were then installed in larger batteries and in each case the production was increased proportionately.

The theory of establishing a single speed and single feed was to eliminate the judgment of the operator and to predetermine the day's output. If this was not obtained the cause was readily detected and almost as readily remedied.

In the machine referred to certain features were introduced which permitted the increase in production. The spindles were much shorter than in a standard lathe, while the bearings and journals themselves were longer than ordinary and much larger in diameter, with the journal bearings of the spindle carbonized, producing glass-hard surfaces.

The driving gears were extremely wide and of the herringbone type to permit smooth action under high speed without any perceptible vibration. The rack and pinion were hardened, as it was discovered that under actual production conditions the severe strains to which these parts were submitted finally bent the teeth very perceptibly and caused them to wear out rapidly.

The handwheel type of tailstock was replaced by a cam attachment for quick approach and withdrawal of the spindle, permitting a travel of from one to three inches according to the requirements of the work.

In order to obtain the squaring of the shoulders during the actual process of turning, a back-arm attachment was incorporated, actuated by the travel of the carriage so that when the longitudinal turning was completed the shoulders were simultaneously finished, thus producing the squaring operation at practically no additional cost. This, however, was not an absolutely new feature, having been previously employed.

To further assist in speeding up production multiple tools are used, and when the pieces are in sufficient quantity and adapt themselves to multiple operations, single-purpose machines of special design are brought out.

A very simple but most efficient method for securing quantity production is to use several arbors, some for loading while the others are working. Also, when applicable, a punch press is used for an arbor press, simultaneously loading one arbor and unloading another, this of course being used only where a battery of machines are operating on the same kind of work and call for a number of arbors of the same size, and where a conveyor is used to carry the work from the press to the lathes and return.

Air cylinders and quick-action, mechanically operated chucking or gripping devices are used wherever possible. Magnetic chucks and plates are also in extensive operation.

Lubrication. The seriousness of having 25 to 100 separate oil holes spread out promiscuously all over a machine is beginning to be realized. The neglect of any one oil hole invariably causes a hold up of production and may mean the entire dismantling of the machine. Therefore it becomes obvious that to control the lubrication from one point is decidedly advantageous. This is accomplished either by supplying a reservoir having gravity feed, by gear pumps delivering lubrication to the various bearings, by the use of the splash system, or by use of force-feed oilers. In fact, there are several methods, all of which are worthy of consideration.

Safety Devices. The working forces of automobile factories comprise many who never saw a machine tool prior to their employment, and it is this class of help that has made it necessary to safeguard every moving part of a machine to prevent them from getting injured. Years ago gears were left exposed and shafts allowed to run in the open, but the machines of today must include guards over every part that is in the least dangerous. Projecting shafts must be guarded, and where it is impossible to supply guards as part of the machine, rails or nettings must be secured around the machine to prevent any possibility of injury.

INFLUENCE OF THE AUTOMOBILE ON GEAR CUTTING AND GEAR-CUTTING MACHINERY

By Henry J. Eberhardt,[1] Newark, N. J.

During the past 20 years the interest of many of our engineers has been especially centered on the successful production and operation of automobiles and particularly automobile gearing.

To produce perfect and noiseless gearing, the trend of effort in gear making has been to produce accurate and rigid machines and cutters. The evolution of these elements divides into periods of great activity. The first period is that of the use of forms, and cutters made to the tooth form, nearly all of the industrial spur and heavy bevel gearing being cut by these means at the present time. Many early gear-cutting machine designs have become obsolete—the 1899 catalog of a prominent international machine-tool dealer illustrated thirteen gear-cutting machines, only three of which are being made today. Machines of this type have been redesigned to use the new alloy high-speed-steel cutters, and are, in the main, rugged examples of specialized automatic machines for the production of gears. As a rule, however, these machines will stand more punishment than the high-speed-steel cutters they use.

The second period is that of the use of gear-tooth generating machinery designed to generate tooth curves from the basic mechanical elements, the straight edge and the circle.

Great credit for early leadership in this period of gear-tooth generation is due to Edward Sang, who in 1827 read a paper before the Royal Scottish Society of Arts, the principles of which he finally crystallized in a treatise published in 1850 and entitled A New General Theory of the Teeth of Wheels.

In this work Professor Sang described a gear-generating machine using a rack-shaped cutter for generating all numbers of teeth; and also a generating machine using a pinion-shaped cutter for the same purpose. All successful gear-generating machines of today are but modification of one or the other of these two types.

The larger proportion of automotive gearing has been made by machines in this second group. However, the exacting requirements of very high-speed gears are not altogether satisfied. Many deviations from theoretical tooth curves have been made, and many changes in the proportions of gear-tooth sizing have been tried, with varying degrees of quiet running at critical speeds.

The third, or present, period of gear making is that in which the cutters are ground after hardening, and which is very prominently exemplified in the recent production of hobs with teeth ground on the top and sides; and also in which the gear tooth is ground after having been hardened. It appears that we are at the very threshold of this period. Several factories are rough-forming their gears on machines of the first and second groups and finishing by grinding.

With finish-grinding of the teeth it is becoming apparent that theoretical generating processes are not essential for the first cutting operation in the soft material. This has led to the production of simple specialized roughing machines, several having multiple spindle features for operating upon more than one blank at a time.

As high-speed-steel cutters are subjected to a melting-point heat in the hardening process, their surfaces become somewhat roughened and oxidized; therefore the value of grinding these cutters, even for roughing purposes, is clearly appreciated by the manufacturers of large quantities of high-grade gearing in a keen competitive market. Grinding such cutters on the top and sides, as well as on the front face of their cutting teeth, removes the roughened layer of oxidized steel and leaves the cutting edges smooth and keen, giving them cutting and wearing qualities much superior to those of an unground cutter.

These refinements of accurate gear making have brought gears to a more advanced state of perfection than the bearings of the shafts carrying them. In the general industrial field, machinery is designed relatively heavy—up to the point of clumsiness—and toothed gearing is given a large factor of safety. Considering

[1] Secretary, Newark Gear Cutting Machine Co., Mem. Am.Soc.M.E.

the automobile as a machine, it is designed relatively light—down to the breaking point—and yet is surprisingly efficient and lasting. Light gear bearings mounted on a flexible foundation will throw the gears out of position for the correct operation of exact tooth curves.

There is also a doubt in the minds of many engineers as to the desirability or mechanical value of adhering to theoretically correct tooth curves. Mr. Hugo Bilgram, in his U. S. patents granted in 1904 on a process and a machine for modifying the shape of gear teeth, refers to the humming noise of theoretical-form gears when running at high speed in the following words:

This may be accounted for as follows: The teeth of wheels, when properly constructed, are made so that one pair of teeth make contact before the exit of the preceding pair, and for a sensible space of time two pairs of teeth remain in simultaneous contact. When the teeth are formed theoretically correct, the pressure to be transmitted will be uniformly shared between the two points of contact while two pairs are in contact, and upon the exit of the receding pair will suddenly fall upon the one pair still remaining in contact. As the succeeding pair come into contact the pressure is again suddenly divided between the two points of contact. This sudden change of pressure and especially the fact that the entering tooth will be expected to instantaneously take one half of the full pressure, readily accounts for the series of shocks manifesting themselves in the humming noises. This noise may be materially reduced if the teeth are so formed that each tooth shall at first take only a small fraction of the pressure to be transmitted and that, as the movement proceeds, the pressure upon the approaching pair shall be gradually increased, while that of the receding pair shall be correspondingly reduced, so that the pressure shall be transferred gradually instead of suddenly from one tooth to the following one. This can be obtained by slightly relieving either at the point or near the base, or both, the surface of the otherwise correctly formed tooth.

In 1902 the author used a gear-generating hob to obtain a similar result. Various successful modifications of tooth forms are being used today. One of the most prominent to be rapidly accepted is a spiral bevel gear, the bearing surface of which is relieved at the large and small ends of the teeth, giving smooth operation even under slight shaft and bearing deflections. The straight-tooth bevel gear is being made with tooth lengths of one-quarter the cone distance, whereas formerly the lengths were from one-third to one-half of the cone distance. Many other variations and special forms are being advocated.

RELATION OF POWER PRESSES AND DIES TO THE AUTOMOBILE INDUSTRY

By Henry J. Hinde,[1] Toledo, Ohio

The art of producing sheet-metal stampings from a flat sheet while cold has made marked progress in recent years, and many articles are now made of sheet metal which were formerly produced by casting or forging, or in a lathe, milling machine, drill press or at the bench.

Forming and stamping operations especially have in many classes of work become very complex, and the art of drawing sheet metals, stimulated by the enormous demand of the automobile industry in particular, calling for most intricate shapes, has reached a state of perfection hardly imagined possible a few years ago. The results achieved by the ingenuity of the present-day press and die designers, and to no small degree also by the metallurgist, who comes into consideration through his improvements of the physical qualities of the metals used, are indeed revelations in economy of production, strength of stamped articles and the absolute interchangeability and beauty of appearance of the finished products.

The development of power presses, together with that of dies and special tools, has been so marked in the last twelve years, principally because of the demand for intricate stampings for the automobile trade, that it is believed a far greater advance has been made than at any other period in the history of the business. This development has not wholly been confined to the working of sheet metal, for, as previously stated, the demand for accurate duplication of parts and the great quantities in which they are desired has resulted in power presses being used for sizing forged-steel parts which were formerly finished by means of saddle milling and similar operations. It has been found that manufacturers can produce greater quantities with much greater accuracy and with such a reduction in machine-shop production expense by the use of what is known as knuckle-joint or cold-swaging presses in sizing the finished working surfaces on these forgings, that a number of equipments have been installed for work on steering knuckles, brake levers, connecting rods and other similar forgings and castings. These presses are built in sizes capable of exerting a pressure up to 2000 tons and over, and it is claimed that size limits of 0.001 in. can be successfully maintained in operations of this character.

Although this marked advance is due to the automobile industry more than to any other one factor in recent years, at the same time the economical production of motor cars was made possible solely on account of the ability of the press and die manufacturers to successfully control the flow of the cold sheet metal into certain forms and shapes, by means of properly constructed dies and presses of such power and design that wonderful results have been obtained. As an illustration of this a wire-wheel hub is shown in Fig. 1.

This hub requires a blank $16\,{}^1/_2$ in. diameter and ${}^5/_{32}$ in. thick. Attention is called in particular to the numerous niches or pockets successfully formed into the circular shape, and also to the fact that the stamping was first drawn to a considerable depth at the narrow neck. The end of the neck or bottom of the stamping was then removed and this metal was made to flow back and expand to a considerable degree beyond its former small diameter without even stretching or thinning the metal in the reforming operations,

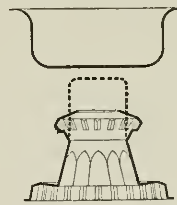

Fig. 1 Pressed-Steel Wire-Wheel Hub Formed from Blank $16\,{}^1/_2$ in in Diameter and ${}^5/_{32}$ in. Thick

thus proving conclusively how successfully the metal was controlled and forced to flow back into its larger diameter with an opening in the bottom much smaller than the former small diameter of the neck of the stamping.

In the production of brake drums, front and rear hubs and spoke flanges the conditions that have to be fulfilled by the dies are that the product shall be absolutely interchangeable; that no machine work shall be performed upon the stampings when coming from the press, excepting some reaming and thread cutting; and that the strength of the material shall remain unimpaired. In addition it is imperative that all cylindrical parts be smooth and true and of standard diameter, allowing less than the commercial tolerance of variation. The work involves a most careful planning of the interrelation of the several operations, so that at no time the material shall be overstrained or reduced in thickness, and that the dies shall not be subjected to excessive wear in order to maintain uniformity of size.

A straight-column press has been developed especially for such work by the Toledo Machine and Tool Company which is of unusually rugged proportions and weighs about 145,000 lb. It is double-geared with a ratio of 40:1 and fitted with a very powerful friction clutch in combination with an effective brake and hand-lever control, so that the machine may be started or stopped at any part of the stroke of the slide up or down. The frame consists of four pieces—the bed, the two uprights and the crown—which are held together by four massive tie rods passing through the said crown, uprights and bed. When the frame is assembled these tie rods are heated. The nuts are then screwed home and the rods permitted to cool. In this manner, through the tendency of the rods to shrink, an enormous pressure is exerted by the rods upon the frame that renders the entire structure practically an integral one and brings all the working stress upon the tie rods.

Axle housings are made of steel plate up to ${}^5/_{32}$ in. in thickness, and the requirements are that the stampings be perfectly straight and flat so that when the two halves of a housing are joined

[1] President and General Manager, The Toledo Machine and Tool Company.

together by welding they form a perfect casing without warp. A powerful double-crank press developed for this purpose weighs about 95,000 lb. and is capable of forming and stamping cold at one blow axle-housing halves about 40 in. in length of steel plate up to $^5/_{32}$ in. in thickness, the blank having been cut previously to proper shape.

One modern form of toggle drawing and deep-stamping press, such as is used for making engine pans, radiators and other similar articles of the comparatively lighter gages of metal, has two slides, an outer slide for clamping the blank and holding it while the work is being drawn, and an inner slide for doing the drawing, stamping and forming operation. Presses of this character are also made in the double-crank type with a considerable distance between the uprights and weighing as much as 600,000 lb. Such presses are used for body forming, for making cowls, dashes, fenders, etc.

The forming of channels and side rails for automobile frames and similar requirements has resulted in the designing and building of special presses particularly adapted for this work. The side rails, for instance, are preferably first blanked in a double-crank press as much as 218 in. between the uprights. The largest sizes of these presses weigh in the neighborhood of 500,000 lb.

The forming operations are performed in a specially designed press, the outstanding feature of which is that the operation is diametrically opposite that of the ordinary toggle drawing or deep-stamping double-action presses. The channel-forming press has a movement entirely mechanical that brings the tools down and at rest on a flat blank, or sheet, by means of a toggle motion, and in this position the machine is capable of a resistance pressure upward of 2000 tons. While this first toggle movement is at rest, another movement is brought into play, forming up the sides of the channel or frame. The machine in its operation completes the one cycle when the stamping lies on the face of the dies completely formed, with the result that the web, or bottom of the stamping, remains as flat as it was in the original sheet. In other words, the bottom or web of the channel is held perfectly flat during the operation. Several of these presses have been built and are in most successful operation. They weigh upward of 600,000 lb. each. One of these presses with five men will do the work of three hydraulic presses with fifteen men, to say nothing of the large force required to straighten the rails when hydraulic presses are used.

Still another interesting feature that the automobile trade has developed is the smoothing-out process for certain of its stampings, more particularly the tapered, stamped-steel radiator front or casing. Because of its slightly tapering form it was found difficult to produce a stamping for this piece so free from waves, or buckles, that it would show smooth over the finally enameled and varnished surface. The requirements were successfully met by developing a set of tools to receive the finished stamping and allow an exceedingly small space for water to flow just inside of the stamping around the steel form supporting the stamping. It was necessary to exert a pressure of some 2000 tons on the outer surface of the stamping to prevent seepage or leaking, and to supply water to the die through a $^3/_4$-in. pipe by means of an accumulator with sufficient force to smooth and iron out all of the unevenness and waves in the original stamping.

THE INFLUENCE OF THE AUTOMOBILE ON LATHE PRACTICE

By Ralph E. Flanders,[1] Springfield, Vt.

Within the memory of the author, the design of machine tools has been deeply affected by a number of influences. The first of these was the bicycle craze of the 90's. An important result was the development of the hand screw machine in the direction of heavier drive and feeds and stiffer structure to meet the demands of work like hub forming. Another line of improvement lay in the design of highly specialized machinery for the making of a single part. Such machinery had been almost unknown up to that time, as the bicycle gave the first opportunity since Civil War days for continuous production on work of moderate size. Machines of this new type were applied to spoke and nipple making, hub drilling, chain-link manufacture, sprocket and gear cutting, etc.

The second great influence was the invention and development of high-speed steel by Mr. Taylor and his associates. The effect of this invention began to be strongly felt in the first five years of this century, and was the chief factor in a continuous policy of redesigning for cutting power and rigidity which has been going on until the present time.

Meantime the high-speed tools themselves have been improved, while the ability to treat them and, still more, the courage to use them to the limit, have been steadily developing. As a consequence there has been a contest between the machine and the high-speed cutting tool much like the classic rivalry between the projectile and the armor plate. As soon as a machine was designed to use high-speed tools to the limit, better tools were provided and speeds and feeds were demanded which were beyond the capacity of any known machine.

The last important influence was that of the automobile. This statement is made advisedly, as the war, so far-reaching in its effect on human life and history, made really little lasting impression on machine-tool practice. A few special processes were fostered, such as thread milling and form grinding. A really revolutionary advance was made in gaging, inspection, and interchangeability in general. This was induced by the necessity for assembling together parts made in widely scattered factories. But the effect on machine tools themselves and their actual operation now appears to have been negligible.

If we study the influence of the automobile on machine-shop practice, we can see why this is so. The industry, long before the war, developed to the point where parts were made in such quantities that most of the operations could be made continuous, one machine or many being set up and tooled for a single operation on a single piece, remaining on this operation hour after hour, day after day, and month after month. In spite of the immense amount of machine-shop work involved in the activities of the war, only a minor percentage attained to this standard condition of automobile manufacture. For the most part it was ammunition and small arms only that were made in continuous production.

Now this condition of continuous production is the ultimate goal of manufacturing development. It demands and employs every last possibility in cutting qualities of steel, power and accuracy in machines; and particularly in skill in the design of fixtures, tool outfits, and methods of machining. The fact that this goal was reached so early in American automobile manufacture explains why the war did not stimulate new developments in machine-tool practice, but rather acted as a retarding factor on the whole.

The influences just described have affected all varieties of machine tools, but this paper is limited to a discussion of lathe practice as affected by the automobile. By lathe practice is meant not only engine lathes, but turret lathes, automatic lathes, automatic screw machines, and other machines in which cutting tools act on rotating work.

For the moment, at least, machines of the best design are more than adequate to the demands of the best high-speed steel now available. Development has therefore taken entirely new directions, and the present is a most favorable moment to examine its progress.

Present progress in lathe practice is in two radically different and, to some extent at least, opposed directions. The one relates to the expanding of the machine by giving it a number of spindles with a corresponding number of tool positions. This is best seen in the multiple-spindle automatic screw machine, now used almost exclusively for standard bolts, screws and studs, and for other parts made in large quantities. It is more costly than the single-spindle automatic, but not much more complicated, the cost arising principally from the extreme accuracy necessary in the indexing and spacing of the spindles. The difficulty of obtaining this accuracy is the limiting feature of the machine, but its scope is constantly increasing.

As applied to larger machines for chuck work on castings, forgings, etc., the machine becomes more elaborate, approaching the conditions of a number of separate machines united on one base. This results in considerable complication and cost, but spectacular producing capacity in many cases. There is the further advantage

[1] Manager, Jones & Lamson Machine Co., Mem. Am.Soc.M.E.

that the tooling—being spread broadly over the different positions—is simple, open, and easily adjusted.

The second line of progress is in the direction of providing machines having a large surplus of driving and feeding power and of rigidity. The limitation on output and accuracy now becomes an entirely new one. Instead of asking, "What will the machine stand?" or "What will the tool stand?" we ask "What will the work stand without springing, breaking, chattering, or tearing from the chuck?" The engineering problem thus becomes one of operation sequence, support for the work, tool design, and—in some cases—design of the work itself.

FUNDAMENTALS OF INTERCHANGEABLE MANUFACTURE

By Chester B. Lord,[1] Battle Creek, Mich.

In dealing with so broad a subject as interchangeable manufacture, it is well to remember that in the course of time many false traditions and pseudo-scientific conditions are built around a process or system, either glorifying it unduly or condemning it beyond its deserts. This makes it necessary to be iconoclastic and tear down that we may build upon a firmer foundation, sometimes rearranging the former material and sometimes rejecting it. Likewise, it is well to start out with certain fundamentals plainly stated, and any discussion or theory that contravenes these fundamentals is useless for our purpose.

The first fundamental is that no two things are alike; the second, that the difficulty of maintaining accuracy increases in geometric ratio with each added accurate dimension on the same piece; the third, that no machine or tool under stress can be accurate; the fourth, that the manufacture of interchangeable parts in quantity is a matter of percentage; and the fifth, that irrespective of the method used, quality is a matter of insistence.

The nearest approach to mechanical perfection that we know of is found in the Johansson gages, or was until the advent of the Hoke gages; but within their limits these are by no means interchangeable and the interferometer shows not only a variation in size but a difference in parallelism of the same piece.

Securing one very accurate dimension on a piece is a comparatively simple matter. The ease of securing two accurate dimensions, however, depends upon the relation of the second to the first. The figures given in the following table are based upon practice and general impressions, but the author believes them accurate enough to justify their publication for the purpose of showing the high cost of unnecessary accuracy:

No. of Dimensions on One Piece	Probable Number of Perfect Pieces	Per Cent Estimated Increase in Ratio of Cost per Operation
1	100	0
2	90	30
3	50	75
4	15	100
5	5	200
6	0	500

In making the foregoing statements the author has in mind automatic and other machines where the close-dimension work is done at one setting and in manufacturing quantities. Some will dispute the figures given in the table and will declare that it is not good practice to attempt finishing pieces in the automatic, but that they should be roughed out there and finished on a shaving lathe or elsewhere. This brings us to our third fundamental and we may ask, Why should they not be finished complete when a good automatic must, in the nature of things, be (and is) as accurate as a single-purpose machine *on a single accurate dimension?* It is not accurate on several close ones, however, and accepted practice confirms this statement; and the reason why it is not and cannot be accurate is because of conflicting stresses.

There are many firms the engineering departments of which really believe they are producing an interchangeable product of close dimensions, but their inspection and manufacturing departments could tell a different story. It is not bad workmanship or lax inspection that is responsible for their failure to produce such work, but the—ofttimes—unnecessarily close tolerances specified on unimportant dimensions, or the insistence of close ones on several dimensions of the same piece, and it is well to stop and consider what may happen, say, to a piece of apparatus after it has been in service for some time when initially it required the centers of two shafts to be held within one-half thousandth of an inch.

Interchangeable manufacture requires both *relative tolerance* and *specific tolerance.* Relative tolerance has to do with its relation to the part to which it assembles and does not necessarily affect the tolerance of the specific dimension. Specific tolerance is that tolerance on a specific dimension required to render a particular part easy to manufacture, or to take care of the wear on tools. Any part increases in cost with each succeeding operation, and the probability of loss should decrease in the ratio of its added value. This result should be obtained, first, by a design having in view its relation to subsequent machining operations, and, second, through the proper sequence of operations relative to their difficulty, and sufficiently divided. This leads us up to the question of registration. Automobile-engine builders cast lugs on their cylinders to insure parallelism of bore; adding-machine and phonograph castings sometimes have bosses cast on, to take the pressure of milling or drilling operations. It is also true that sometimes we insert a pin in a drilled hole to guard against movement, but we do it only at times and usually as a matter of convenience, whereas it is a matter of necessity; and it will usually cost less to drill special holes or machine special lugs for registration and resetting than to attempt to do the work in fewer complex operations.

And nearly as important as registration is the question of clamping. One of the fundamentals laid down was that a machine under stress could not be accurate. This is just as true of a piece being machined, and unless a part is designed with its subsequent machining operations in view; unless it is supported sufficiently near its pressure centers; unless it has a three-point support with the holding or clamping pieces immediately over them (and in the case of a drill jig, independent of the part that carries the bushings), then that piece cannot be accurate. This is true of drilling always, of milling generally, and of turning sometimes.

How tolerances shall be indicated; whether they shall be identical, independent, or overlapping; what the law of probability and what actual trial demonstrate as the probability of overlapping or identical tolerances interfering; the percentage that may be expected at different parts of the tolerance, and the lessons to be learned therefrom are subjects calling for extended treatment by themselves. The same is true of inspection, of machining methods, of analysis of product.

The automatic screw machine will, of course, always be with us, for in that we meet ideal manufacturing conditions as nearly as they may be met. But the fact that the single-spindle screw machine persists and is even exclusive in the small-part field, is still further corroboration of the price we must pay for accuracy. The question of accuracy is of course relative, as is the question of rigidity of machine; but it is important in its bearing upon the cheapness of manufacture by determining the number of cuts, retapping, reaming, grinding, etc., that are necessary.

The law of compensation applies to mechanics as well as elsewhere in industry, and when we attempt to work to closer limits at the expense of increased operations, we must pay somehow. This is not to be considered as an argument against such a procedure, but an appeal for common sense in interchangeable manufacture—not to make the work easier, but to reduce the cost—and the firms that are really making a good interchangeable product are those that have analyzed all the different conditions and hold the extremely accurate dimensions at a minimum.

Neither should it be thought from what has been said that close dimensions may not be necessary or desirable. Some companies require them much closer than do others. It then becomes a question of whether the price received for the finished apparatus is commensurate with the close limits imposed. If not, then it is a matter of increasing the tolerances so as to permit manufacture on a cheaper basis. In other words, the percentage of rejections that can be tolerated must be figured out and kept within that limit. For instance, on an apparatus costing $10.00 for which a liberal price is asked and received, an allowance of 50 cents per apparatus for rejections may not be excessive. If, on the other hand, the price is close, 50 cents may mean the difference between profit and

[1] Works Manager, Advance-Rumely Co., Mem. Am.Soc.M.E.

loss. This is a matter of policy to be settled by the administration and not by the shop, although we very often lose sight of this fact.

In the author's opinion there are no such things as close tolerances. All are relative and we only court trouble when we try to take too many steps at once. One-half thousandth is only five per cent of ten thousandths, and the chance of securing that accuracy in quantity in one step is about five per cent multiplied by the extra cost. But one-half thousandth is *fifty per cent* of one thousandth and the probabilities are increased in the same ratio, so we may lay it down as a truism that subdivided operations are a function of accuracy.

Analyzing our fundamentals, we find that there are three ways in which interchangeable parts may be secured:

a By obtaining a percentage of good ones, with close tolerances
b By giving individual attention to each piece
c By employing liberal allowances

The first is wasteful and the second is not manufacturing; the third one means liberal unnecessary allowances and close necessary ones, with the operations so divided that each individual working upon the part has but one thing to do. Thus, on a small shaft with six diameters all ground to a 0.0005-in. limit, there should be six roughing and six finishing operations because different wheels may be used; because less skilled men may be employed with less chance of scrap; because the wheel will be in better condition and will not need dressing so often and the operator will not have to change his sense of proportion, "hog off" material one moment and hardly touch it the next; because the finishing operations may always be done on the most accurate machine; and last, but not least, because as a rule one man can finish more work to close dimensions in four operations than four men can in one operation.

Let us not delude ourselves, however, that interchangeable manufacture or standardization is all profit and has no penalties. The French, even in large business, recoil from the idea of standardization, and this feeling has saved them through the ages from the rigidity of an arrested civilization. I am not competent to say whether the artistic qualities of the French are the result of their fight against standardization or whether it is the cause. Suffice it to say that no country that manufactures on the scale that France does and employs standardized methods, can either duplicate her excellence of manufacture or produce the artistic or scientific results she obtains. We must somehow pay for the repetition we call standardization, specialization, or interchangeability, and as usual the toll is collected from the intellectual.

DISCUSSION AT THE MACHINE SHOP PRACTICE SESSION

THE discussion was opened by Luther D. Burlingame[1] who spoke of the influence of the automobile both on the use of the machine tool in their manufacture and to its use in providing the tool and gage equipment needed for quantity production. In the case of the milling machine, power feeds in all directions had been added, with automatic quick return, with constant-speed drive and gear changes for the feeds and spindle speeds controlled by levers conveniently adjusted; while in the case of gear-cutting machines, the call for gears of a higher degree of accuracy and strength, combined with quiet running, brought new problems. Much study, he said, had been given to the question of the worm drive and to the development of steels and other materials which had reacted on the industry in a way to increase very noticeably the efficiency and durability of machine tools. Machine tools are depended upon in the manufacture of gages and tools and in this field of work alone, he said, there has been a special challenge to increase the degree of accuracy and high grade of workmanship needed for the manufacture of the machines needed for producing this tool equipment.

J. A. Smith[2] spoke of the need for strengthening machine tools, expressing his belief in "lots of iron." Machines could have precision without being specialized, he said, the opportunity for specialization being greater in the larger manufacturing plant having a small variety of products. There should be plenty of power, so distributed in a machine that the place of power application should be the place of failure in case of overloading. He criticized the lubrication of machine tools, which he considered the least up-to-date feature.

Chester B. Lord[3] expressed himself as being dissatisfied with the lubrication of machine tools and criticized the builders in not taking the lead in making improvements along this line. He objected to "specialization" saying that "simplification" was needed. He also objected to the many speeds and feeds.

N. W. Dorman[4] took up the cudgels for the machine-tool builders on the matter of lubrication and spoke of the thought and care with which they had considered this problem.

F. O. Hoagland,[5] chairman of the meeting, then started a discussion of the color which machine tools should be painted. Chester B. Lord said his practice was to enamel all machines upon which girls worked white, while J. A. Smith thought he would like to have machines painted a light gray. C. W. Ripsch[6] said his company's practice was to use a battleship gray, and Roger B. Garvin[7] complained that each customer would want a different color should machine-tool builders commence such a practice.

In discussing punch presses, J. A. Smith again spoke for more material, such as bigger shafts, and for the location of bearings so that they would be accessible.

Forrest E. Cardullo,[8] who presented the paper by Mr. Hendrickson, was asked to close the discussion and spoke of the fact that tools which were not primarily used in automobile manufacture had also been improved. He took sides with the manufacturer on the subject of lubrication, maintaining that it should be the duty of some one to see that machines were properly oiled. He considered the value of weight of metal in machine tools an exaggerated idea; correct design would eliminate useless weight. He was also of the opinion that purchasers of machine tools always expected more of the tool than their original requirements and for this reason were apt to brand it as unsatisfactory.

A. C. Cooke spoke of a number of details of automobile practice and design which had been adopted by machine-tool builders. One of the most valuable outcomes of the relations of the automobile and machine-tool builder, he thought, was the coöperation between them which had resulted in improvements.

Sol Einstein[9] in a written discussion, mentioned many of the improvements to milling machines which had come about through the demands of the automobile industry and of the details of automobile design and practice which had been adopted by machine-tool builders. He summed up his remarks by saying: "The automotive industry asked of the machine-tool designer automatic machines, either through modification of standard designs or machines of entirely special design—quick-acting fixtures, either hand-operated or automatically operated—more powerful and stronger machines occupying a minimum amount of floor space. On the other hand, the automotive industry supplied the machine-tool designer with a vast variety of highly successful mechanisms and constructive details, from which he could draw freely such elements and such ideas as could be adapted to the design of machine tools."

Following the discussion of these papers, Chester B. Lord presented his paper on the Fundamentals of Interchangeable Manufacture. The discussion of the paper turned to the question of tolerances, location surfaces and standards. Those participating in the discussion were Messrs. Smith, Cardullo, Hoagland and Lord.

Limitations of Stokers Using Mid-West Coals

Two papers dealing with the limitations of stokers using Mid-West coals were presented at the Fuel Session of the A.S.M.E. Spring Meeting in Chicago, and appear below in slightly abridged form.

In the first paper the author, Mr. E. H. Tenney, discusses the limitations imposed on mechanical stokers by the use of Mid-West coals, which are characterized by higher moisture, volatile and ash contents as compared with Eastern coals; the limitations imposed by air supply and by the design of the furnace; and the effect of these various limitations on stoker operation. It is his belief that in general the application of mechanical stoking equipment to the use of Mid-West coals has proved to be eminently successful. Specially designed arrangements for air supply and to facilitate ignition of the fuel have been provided; and furnace volumes and gas passes have been scientifically studied, with the result that the most difficult problems—namely, those incident to operation at high rates of combustion—have been satisfactorily solved.

According to the author of the second paper, Mr. John E. Wilson, less progress has been made in the direction of securing efficient combustion than in any other immediately connected with stoker service. In the case of natural-draft chain-grate stokers the greatest losses are those due to the dry chimney gases and the carbon in the ash, and the possibility of making a material gain in the efficiency lies to a great extent in the ability to reduce these two losses. A certain amount of air admitted over the fire has been found advantageous when high-volatile coals are used, such as those found in the Middle West.

Capacity is governed principally by the available draft and ratio of total boiler heating surface to the grate area. Chain-grate stokers provided with forced draft operate successfully under continuous high rating, respond quickly to load requirements, and will successfully burn coal containing a large percentage of ash which fuses at a comparatively low temperature.

Underfeed forced-draft stokers in the Mid-West districts have a large number of very satisfactory operating records to their credit both from an efficiency and a capacity standpoint. Some types of overfeed stokers have also been used with good success in this section where only a limited capacity was required and suitable coal was available.

The necessity of securing improved refractories as well as improving the furnace design is emphasized by the difficulties encountered with the brickwork when forced firing is employed, and it is possible that these may prove factors governing the capacity which will be obtained in future installations.

LIMITATIONS OF MECHANICAL STOKERS UTILIZING MID-WEST COALS

By Edward H. Tenney,[1] St. Louis, Mo.

A CONSIDERATION of the limitations of mechanical stokers imposed by the use of Mid-West coals is pertinent at this time on account of the increasing application of mechanical-stoker equipment throughout the Middle West, and on account of the tendency on the part of some to overlook the fact that such limitations exist.

Limitations Imposed by the Fuel

Mid-West coals are classed as bituminous or sub-bituminous, and are characterized by the higher percentages of moisture, volatile and ash which they contain as compared with Eastern coals (see Table 1). On account of these characteristics they are inherently difficult to handle satisfactorily on a stoker, but they present possibilities for even greater operating economies than in the case of Eastern coals because of the opportunities provided for even firing, close regulation of air supply, high temperatures, and a continuous and regular elimination of ash.

TABLE 1 COMPARISON OF EASTERN AND MID-WEST COALS

Constituents of Coal	An Eastern Coal[1]	A Mid-West Coal[2]
Moisture, per cent	2.21	11.90
Volatile, per cent	15.78	31.06
Fixed carbon, per cent	71.65	41.62
Ash, per cent	10.36	15.42
	100.00	100.00

[1] Pocahontas. [2] Southern Illinois.

Moisture. The moisture content in Mid-West coals ranges from 6 per cent to 16 per cent, depending largely upon the amount of surface moisture which may be present. This moisture absorbs heat from the furnace for its vaporization and superheating and tends to reduce furnace temperatures, often to such an extent as to be the limiting factor in the obtaining of proper ignition at high rates of combustion.

Volatile. High volatile content is the one redeeming feature of the Mid-West coals, inasmuch as this quality tends to facilitate ignition. With other furnace conditions favorable to the proper combustion of the liberated gases, there is little doubt but that the limit of stoker capacity is increased by the increased percentages of volatile.

Ash. The ash content of these coals varies from 10 per cent to 16 per cent, depending upon the method of mining and storing, and presents one of the most difficult limitations to their use on mechanical stokers. Large quantities of incombustible matter interfere with combustion if allowed to remain in the active fuel bed. This is increasingly true at high ratings, especially so on account of the low fusing temperature of the ash, which results in the formation of clinker and the prevention of proper air supply. The efficiency of the combustion process and the effectiveness of the stoker for burning large quantities of coal at high rates of combustion are seriously limited by this clinkering quality in the Mid-West coals. This characteristic can be closely approximated from an analysis of the ash, although the grouping of elements and the reactions at different temperatures vary to such an extent that no rule can be applied. Table 2, prepared by Mr. Edwin Lundgren,[2] shows the increase toward fusibility as percentages of certain constituents change, more particularly the ferric oxide. Ash from Mid-West coals comes between "clinkering" and "bad" in the table.

TABLE 2 TYPICAL PERCENTAGE ASH ANALYSES

Composition	Non-Clinkering	Fair	Clinkering	Bad
Silica (SiO_2)	54.67	46.23	46.40	43.50
Aluminum (Al_2O_3)	41.95	31.93	16.45	17.10
Ferric Oxide (Fe_2O_3)	Trace	14.54	18.15	28.10
Calcium Oxide (CaO)	1.82	5.04	11.80	5.30
Magnesia (MgO)	1.42	2.26	4.63	0.75
Sulphur	0.55	1.50	3.00	2.70

Limitations Imposed by Air Supply

The subject of air supply to stokers utilizing Mid-West coals is of equal fundamental importance to that of the fuel itself. In the burning of low-grade coals the distribution of air through a fuel bed heavy with ash and clinker is not conducive to its proper mixture with the combustible gases, with the result that combustion is incomplete when the gases have passed from the furnace. Such coals require large quantities of excess air, which, on account of the interference set up by the fuel bed, tend to travel in stratified streams. The mixing, therefore, is incomplete and the combustion slow. Where natural draft is utilized, it is obvious that air supply is one of the important limiting factors as to efficiency in the use of these coals. Where artificial draft is utilized, air supply is seldom a limiting factor. Care must be exercised, however, in the specification of equipment for varying qualities of fuel in order that provision may be made for sufficient capacities when burning low-grade fuels at high ratings. This involves the use of quantities of excess air at high temperatures and may become a serious limiting factor.

Limitations Imposed by the Design of the Furnace

The size of the combustion chamber, in that it determines the length of time during which the mixture of combustible gases and air will remain in the furnace, determines the amount of fuel that can be burned, and hence determines stoker capacity. For high ratings where large quantities of gas are produced and large volumes of air supplied, a limit is reached when the furnace gas and

[2] Vice-President and Chief Engineer, Frederick Engineering Co., Frederick, Md., Assoc-Mem. Am.Soc.M.E.

the oxygen in the air supply cannot remain in contact in sufficient time to completely burn the gases. With 50 per cent excess air and burning at the rate of 50 lb. per sq. ft. of grate area per hour, developing to within one-half of one per cent complete combustion of the flue gases, the Bureau of Mines[1] have determined that Illinois coal requires 11.9 cu. ft. of combustion space per sq. ft. of grate area as compared with 4.8 cu. ft. in the case of Pocahontas coal. In other words, to obtain like results at very high ratings the Mid-West coals require about two and one-half times as much furnace volume as the Eastern coals.

For high overratings with Mid-West coals very large volumes of flue gas must be handled. Resistance to the passage of these gases through the setting increases as the square of their velocity. At high ratings, therefore, the drop in pressure through the furnace and boiler increases rapidly, at 200 per cent of rating becoming four times the drop at 100 per cent rating, and at 300 per cent of rating becoming nine times the drop at 100 per cent rating. Draft pressures must therefore be adequate to overcome these high frictional losses or capacity will be limited. Location of baffles to give uniform velocities throughout the path of gas travel is an extremely important phase of boiler and furnace design which, until recently, has had too little serious attention and has been a limiting factor in boiler efficiency.

The problem of ignition offers another limiting factor in the operation of stokers using Mid-West coals, especially at high overratings. Furnace design must permit of the concentration of sufficient heat at the point of entrance of the fuel to accomplish a rapid distillation and strong ignition of the hydrocarbons. The necessity for, and the practice of, installing a properly designed reflecting arch to accomplish this is well known. The high volatile percentage of our Mid-West coals tends to facilitate ignition and is especially favorable when the volatilization may be accomplished rapidly and at comparatively low temperatures. This produces the greatest percentage of methane (CH_4), which is the simplest hydrocarbon and most easily consumed. Successful ignition also depends to some extent upon the size of the coal, smaller sizes igniting more quickly than larger lumps on account of the greater surface displayed to the heat.

Effect of Limitations on Operation

The effect of these various limitations in the case of chain-grate stokers utilizing natural draft is that maximum capacity is limited to the burning of from 40 to 45 lb. of coal per sq. ft. per hour, which may be somewhat increased at a large sacrifice in efficiency. Above this rating, however, the ash-pit loss increases excessively, and it is almost impossible to maintain ignition. In the case of forced-draft chain grates the limits as to rates of combustion are considerably higher, and greater flexibility of operation is also obtained through a more definite control of air supply. However, when the coal rate is increased beyond approximately 60 lb. per sq. ft. per hour, clinkers and slag complications make efficient operation difficult. In addition to this, temperature conditions at high ratings become such as to make furnace and brickwork maintenance a serious problem.

In the case of the overfeed type of stoker, operating under natural draft, a coal consumption somewhat less than that obtainable on the chain grate is generally recognized, this being approximately 30 lb. per sq. ft. per hour. Trouble from the avalanching of the fuel bed is reported beyond this rating resulting in breaks and bare spots within the fuel bed and temporarily limiting both efficiency and capacity. In the application of forced draft to overfeed types of stoker overratings may be somewhat extended. A test by the Bureau of Mines on a Murphy-type stoker developed a combustion rate of 50 lb. per sq. ft. per hour.

In the case of the underfeed stoker, particularly where equipped with multiple retorts and forced draft, a quick response may be had to all changes in load, resulting in an exceedingly flexible control. For continuous operation the maximum amount of coal which can be burned successfully seems to be from 900 to 1000 lb. per retort per hour. For high overratings over short periods a combustion rate of 1400 lb. per retort per hour may be established. The limiting features as to capacity and efficiency in the underfeed stoker utilizing Mid-West coals lie mainly in the high ash content of the fuel and its low fusibility, which at high overratings result in clinker formation and sometimes in the fusing over of the entire surface of the fuel bed adjacent to the dump plates. While such conditions are being rectified combustion is partially suspended, capacity limited, and efficiency low.

In conclusion, it may be generally stated that the application of mechanical-stoking equipment to the use of Mid-West coals has proved to be eminently successful. The peculiar characteristics of the fuel have called for especially designed arrangements for air supply and for ignition. Furnace volumes and gas passes have also had scientific attention, with the result that the most difficult problems, namely those incident to operation at high rates of combustion, have been satisfactorily solved. The particular type of stoking equipment best adapted to these coals may be specified as that one which most fully overcomes the many limitations to capacity and efficiency which have been found to exist.

[1] Bulletin No. 135 (1917).

CAPACITY AND EFFICIENCY LIMITATIONS OF STOKERS USING MID-WEST COALS

By John E. Wilson,[1] Chicago, Ill.

The cost of stoker repairs per ton of coal burned depends to a large extent on the quantity of coal consumed per square foot of grate surface, or its equivalent, rather than on the type of stoker used. The average cost of repairs to a number of chain-grate and underfeed stoker installations has been found to be 3.7 cents and 5.4 cents, respectively, the cost of repairs to the fans and air ducts required by underfeed stokers being included in the latter figure. The chain-grate plants mentioned will burn, on an average, 30 lb. of coal per sq. ft. of grate surface per hour, while the underfeed stoker plants will average 550 lb. per retort per hour.

In considering the repair and operating records from numerous plants, the fact has been brought out that the stoker is one of the most dependable pieces of equipment in the power plant. The stoker, up to the present time, has been primarily a labor-saving device. The importance of this feature has increased with wages, together with the uncertainty and scarcity of labor. The decision to install stokers in many plants has been governed to a large extent, if not entirely, by this factor. The saving in the cost of operation effected by stokers is frequently considered along with the saving made by the coal and ash-handling machinery. In this way the total saving often appears credited to the stokers alone. Since all or part of the coal-handling, and all of the ash-handling, equipment is applicable to a hand-fired plant, care should be taken to make a distinction between these figures. The quantity of steam required for driving stokers, also for draft fans, should in all cases be charged against stoker operation when considering these costs. The quantity of steam required for this purpose will vary from 0.3 per cent on stokers using natural draft to 3 per cent where induced or forced draft is used.

Mechanical Stokers from the Standpoint of Efficient Combustion

Upon considering mechanical stokers from the standpoint of efficient combustion, it is apparent that less progress has been made in this direction than in any other immediately connected with stoker service. The saving due to the increased efficiency obtained with stokers over hand firing will cover only to a small extent the fixed charges on the increased investment required by the stokers.

Chain-grate stokers operating under natural or induced draft have been used extensively through the Middle West for a number of years. In supplying coal to the stoker magazine it is the usual practice to feed it from an overhead bunker through chutes. In gravitating down the chute the various-sized pieces of coal have a tendency to separate from one another. This action causes the coal to be delivered in the magazine with the small coal in the center, increasing in size toward the ends. The result of this is a marked tendency for the fire to burn off unevenly. The use of overhead

[1] Traveling Engineer, Swift & Co. Mem. Am.Soc.M.E.

Slightly condensed from a paper presented at the Spring Meeting, Chicago, Ill., May 23 to 26, 1921, of The American Society of Mechanical Engineers. All papers are subject to revision.

lorries for weighing coal to the stoker magazine eliminates this condition to a large extent.

A large percentage of the screenings, or slack coal, used on chain grates will pass a 1/2-in. mesh screen. In some cases this fine coal has found its way to the sieving pit in such quantities as to represent 15 per cent of the total amount of coal fed to the grate. As a rule the sievings are either conveyed back to the main coal bunkers, or returned directly by hand to the stoker magazine. A comparatively small quantity of this coal on the grates will be sufficient to upset conditions in the furnace, resulting in lower capacity and efficiency. Efforts to reduce the amount of sievings by providing air openings running diagonally across the links, also by substituting skids in place of rollers, have been only partly successful.

The design and location of the furnace arch have an important bearing on the operation of a chain grate, both from an efficiency and capacity standpoint. It is highly important that the hydrocarbons driven off from the coal in the distillation zone at the front of the stoker be consumed in the furnace before having an opportunity to come in contact with the heating surface of the boiler. The ignition rate is governed principally by the design of the arch, and this affects the quantity of coal consumed to a large extent.

The following figures are those of a representative heat balance from boilers equipped with natural-draft chain grates burning Illinois coal:

	Per cent
Heat absorbed by water	70.0
Heat loss due to dry chimney gases	14.5
Heat loss due to combustible matter in the ash	5.5
Heat loss due to burning of hydrogen	5.0
Heat loss due to incomplete combustion of carbon	1.5
Heat loss due to moisture in coal	0.5
Heat loss due to moisture in air	0.5
Heat loss due to radiation and unaccounted for	2.5
	100.0

It will be seen from this that the greatest loss from any two combined sources is from the dry chimney gases and carbon in the ash. This indicates that the possibility of making a material gain in the efficiency lies to a great extent in the ability to reduce these two losses. The importance of reducing the excess air is apparent, since some 40 per cent of the loss due to heat carried away by the dry stack gases results from the excess air admitted to the furnace. The most serious fault, perhaps, of the chain-grate stoker is the failure to provide adequate facilities for controlling the air supply to the furnace. Adjustable dampers have been installed on some natural-draft chain grates for this purpose, but the results obtained are only partly satisfactory. If attempt is made to burn the carbon out of the ash, it is found that an increased amount of excess air is admitted through the rear of the grate.

The short-circuiting of air through the well-burnt-out ash, in addition to carrying heat away from the boiler, tends to slow down the ignition and combustion rate on account of reduction in furnace temperature. On the other hand, if the fuel bed is carried well up to the water back, an excessive amount of carbon will be wasted in the ash. On account of the conditions just mentioned, after a certain point is reached the combined loss from stack gases and carbon in the ash remains approximately the same—a gain in one being offset by an additional loss in the other.

The baffle found on chain-grate stokers at the rear of the grate helps to prevent an excessive amount of air from finding its way into the furnace between the water back and grate. The condition which tends to discount the good to be derived from the baffle is the variation in size and nature of the coal, which makes it difficult to maintain a uniform length of fire extending up to the water back at all times. The stoker baffle is necessarily located in a place difficult of access, with the result that it is likely to be neglected.

Various experiments have proved that a certain amount of air admitted over the fire is an advantage where high-volatile coals are used, such as are found in the Middle West. This will be appreciated when consideration is given to the fact that practically no free oxygen passes through an active fuel bed of a uniform thickness which would be available for uniting with the combustible gases driven off of the coal soon after it passes into the furnace. With the present stoker design there is no doubt considerable air leaking in around the ledge plates, coal gate, etc., which furnishes in a more or less uncertain way some of the air required above the fuel bed.

The chain grate disposes of the ash very successfully, even from coals which run high in ash having a comparatively low fusing point. This is a material advantage as it permits the use of high-ash coal, which is practically valueless on account of clinkers when used on other types of grates.

The various factors enumerated in the preceding paragraphs relate primarily to efficiency. Operating records from a large number of plants show that an actual operating overall boiler efficiency of 70 per cent is difficult to maintain. This covers plants where natural draft is used and boilers are not equipped with economizers.

Limitations Governing Capacity of Stokers

The capacity is governed principally by the available draft and ratio of total boiler heating surface to the grate area. With a draft of 0.35 in. over the fire and a ratio of heating surface to grate area of 50 to 1 or less, a capacity of 170 per cent of rating should be obtained without any sacrifice in efficiency. When the ratio of heating surface to grate area is around 60 to 1, a capacity of 140 per cent rating is seldom exceeded. This is based on an available draft of 0.35 to 0.40 in. over the fire.

In many installations where the boilers are equipped for induced draft, ratings of 180 per cent to 190 per cent, and even higher, are obtained with chain grates. It is common practice to use economizers in connection with induced draft.

It has been pointed out in a number of instances that small plants burning from 50 to 150 tons of coal a day operate very economically as compared with larger plants in the same district. This is due in a large measure to the fact that the supply of coal for the small plant is obtained from one source. Under these conditions the furnace design may be changed to suit the coal used, and the most satisfactory method of operating the stokers can be determined and adhered to. The coal for the large plant, on the other hand, is secured from a number of different sources and varies materially in quality and other characteristics. This requires very close attention in order to make the numerous changes necessary in the feed, air supply, etc., to suit the different coals.

Several different makes of forced-draft link or chain-grate stokers have been placed on the market in the past few years. A number of installations of this type of stoker are to be found in the Middle West. In making provisions for furnishing air under pressure below the fuel bed, wind boxes and dampers were installed in such a way as to divide the fuel bed into several zones. The control of the air supply to any zone can be regulated independently of the other sections. This feature makes it possible to admit the air to the fuel bed where it is required, and in the proper quantity. It follows that an increased efficiency is obtained, as the excess air is reduced to a minimum. The quantity of unburned carbon in the coal is also much less than found with other types of stokers. The increased investment required by the forced-draft chain grate, however, together with the increased cost to operate, materially cuts down the saving in money due to the increased efficiency. The satisfactory operation of this type of stoker under continuous high rating and the quickness with which it responds to load requirements form a very important feature. It is possible to use coal containing a large percentage of ash which fuses at comparatively low temperatures without any difficulty on this type of stoker, and at the present time is without doubt better adapted for burning the Mid-West coals economically at high ratings than any other stoker on the market.

Underfeed forced-draft stokers in the Mid-West districts have a large number of very satisfactory operating records to their credit, both from an efficiency and a capacity standpoint. The difficulties experienced with holes burning in the fuel bed, where a thickness of 6 to 7 in. is carried, are eliminated on the underfeed. This type of stoker shares the advantage with other forced-draft stokers of being able to bring a boiler up to 250 to 300 per cent rating in a very short time. The nature and quantity of ash in the coal form probably the most important single item governing the successful operation of underfeed stokers. With a heavy fuel bed the tendency is for the ash to ball up and clinker, preventing the carbon from being burnt out in the furnace. This condition at the same time tends to interfere with the continuous operation of the stoker at

(Continued on page 561)

Organization of an Engineering Society Discussed at A.S.M.E. Spring Meeting

At the Spring Meeting Business Session there was presented a paper by Morris L. Cooke on the Organization of an Engineering Society. As the subject of this paper, which was procured by the Management Division, was of a fundamental management character, the discussion thereon was held at the Management Session.

This paper, with the discussion relating thereto, is of especial importance at this time when the revised constitution and by-laws of the Society are being presented for consideration and discussion by the membership. The draft of the new constitution and by-laws is given in Part Two of this issue in parallel form with the present constitution and also with the notes of discussion presented at the Business Session. The new constitution and by-laws will be discussed at the Annual Meeting Business Session and will be presented to the membership for letter-ballot in March.

The first discussion was presented by R. M. Gates, managing engineer of The Lakewood Engineering Company, Philadelphia,

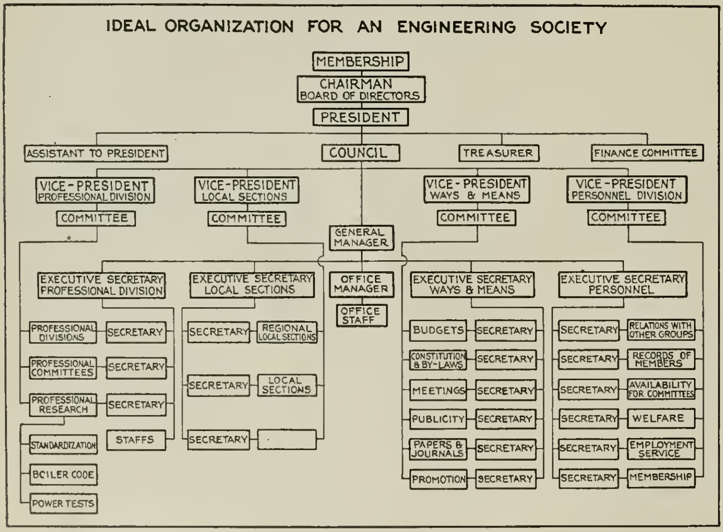

Fig. 1

and H. V. Coes, manager of Ford Bacon & Davis, Philadelphia. These gentlemen defined the engineer as a man whose knowledge of the application of the physical laws and the technic of industries enables him to direct the use of the forces and materials of nature in anticipation of and daily solution of economic needs. Stating the purpose of the engineering society to be the promotion of the technical interest of its members, they gave the following methods of procedure:

1 Technical meetings
2 Intensified technical research
3 Bureau of technical information
4 Public representation of the engineering fraternity at large.

They classified the average society membership into two groups, —those who desire to take part in the technical work of the society, and those who are interested in engineering and in committee work relating to the promotion of engineering. The latter total possibly ten per cent of the Society membership, the balance of ninety per cent being made up of those who desire to keep in contact with their fellow-engineers and those who join under any one of a number of pretenses and who are generally indifferent.

Messrs. Gates and Coes stated the problem of society organization to be (*a*) reorganization of the method by which a society functions, and (*b*) the development of a plan to secure active participation of the indifferent members.

The discussers likened the engineering society to an organization for the production of engineering knowledge and service. They discouraged the committee idea as slow and cumbersome and presented the chart, Fig. 1, showing the proposed organization. In this chart the sales or distributing division is represented by the Local Sections activity; the production department is likened to the Professional Divisions; the administrative department to the Ways and Means Division. The duties of each of the parts of the proposed organization are listed as follows:

Professional Divisions should be required to furnish the programs, papers, discussions, research. Local Sections should advertise the professional work of the Society and arrange for local meetings. The Ways and Means Division should handle the business and operation of the Society, finance, rules, national meetings, publications, etc. Each of the groups should be directed by a vice-president of the Society. Each major sub-division of each of these groups should have a manager or chairman: These would be chairmen of our present Professional Divisions and chairman of each regional Local Section.

The Board of Directors should consist of a president elected by the membership at large, the three preceding past presidents, a vice-president in charge of Professional Divisions elected by the Professional Divisions members, a vice-president in charge of Local Sections elected by the Local Section members, a vice-president in charge of Ways and Means Division elected by the membership at large, a vice-president in charge of Personnel elected by the membership at large, and a treasurer elected by the membership at large.

The Council as now constituted would become an advisory board without power to execute and would consist of the chairmen of the principle sub-divisions under each vice-president.

Because of the magnitude of the responsibilities of the president with the term of office only one year as under the present system, it is recommended that a general manager be employed who would be responsible for the operation of the society to the directorate through the president. This general manager should be virile, broad-gaged, able executive.

To handle the activities of the Society so that the present indifferent members will take active interest, these members should be subdivided into the following:

1 Engineers of confining work that have limited vision and a lack of ability to get acquainted
2 Men in engineering work in isolated territory whose inability to attend meetings makes them indifferent
3 Those who have become displeased over some method used by the Society or some difference of opinion.

To cope with this problem the fourth vice-president should direct membership relations with other groups, welfare, records of membership, employment and men available. His records should contain a complete report of the activities and the ability of each member. Those who are inactive should be approached either personally or through the mails, to impress upon them their responsibility in contributing to the welfare of the engineering profession. This division would afford them an avenue of approach to the professional, local or ways and means divisions of the Society, where they might assist on committees and participate in the carrying out of the Society's ideals. There are innumerable ways in which a department under such a division could be of great value to the membership of the Society.

H. J. Laski, of the School of Economics and Political Science of the University of London, presented a written discussion combining a number of valuable suggestions. Most important of these was the development within the A.S.M.E. of groups to undertake surveys of the regional problems of the country, pooling the results to obtain a catalog of the engineering needs and thus providing a basis for subsequent action. Other suggestions of Mr. Laski's called for representation of younger men on the Council, separation of policy from administration, and a setting up of a

research organization to make expert criticisms on public engineering products and to give advice to public authorities. He also suggested the study by the Society of conditions of appointment and tenure of engineering posts in the public service with constant scrutiny of such appointments and public announcement when they are unsatisfactory.

Dr. F. H. Newell, consulting engineer, Washington, D. C., emphasized two particular points brought out by Mr. Cooke as to the necessity for increasing the activity of the individual member and the need for an engineering organization to develop a method whereby the task of the engineer in an organized group can be kept abreast of the best thought of the profession and the times. In discussing the need for developing individual activity, Dr. Newell compared the activity of engineers in their regular employment and in the Society. In one case the man is impressed with his duty to deliver the goods and in the other case it is rarely brought to his attention that he has a larger duty or that it would be desirable to try to utilize the full man power of his associates, especially of the younger and newer members who may be regarded simply as an audience, or background against which may be displayed the special qualities of some leader in the profession. The traditional attitude of the Society may discourage the interest and activity of the younger men who should be attracted and inspired. Lack of opportunity for individual activity and a tendency to a conservative attitude tending to keep the control of affairs as exclusively as possible in the hands of a few men will repulse the younger man. Dr. Newell pointed out that in the case of the commercial organization the employee's interest is stimulated by compensation either in salary or in satisfaction received. The engineering society compensation must be entirely that of satisfaction received. This satisfaction may be personal contact and acquaintanceship rather than scientific or technical information. However, engineers are not sociably inclined. Dr. Newell stated that after a generation of attending engineering meetings he was not conscious of having enlarged his acquaintanceship in anything like the proportion which should have been possible. He emphasized the importance of making each member responsible for increase in membership, as there is no way of appreciating an organization better than by trying to convince another person of the benefit of belonging to it and taking part in its work. Dr. Newell also emphasized the necessity for direct appreciation of work done by officers and active members. Even though the recognition may be trivial in itself, it should still be a tangible testimonial of service rendered or skill shown.

In developing the idea that the engineering profession should be kept abreast of the times, Dr. Newell stated that papers and discussions have too often been in the nature of an autopsy of a dead issue rather than a diagnosis of real existing conditions. Live, debatable subjects will keep an organization awake and add to its efficiency. Many a responsible officer of an engineering society has urged that it would be impolitic and unwise to discuss such matters in open meeting; such discussions are the very things most needed at the present time. In closing, Dr. Newell emphasized again the necessity for showing proper appreciation of service freely given or offered by individuals or groups of less well-known members.

In an oral discussion S. N. Castle outlined the broadening of the mechanical engineer during the past thirty years with the coördinate development of the Society's organization. He emphasized the point that the Society must receive its impetus for growth from its membership but that this growth should develop effective citizenship by the better use of engineering and technical judgment. He strongly urged an effort to secure the interest of the young man entering upon an engineering career either in school or in an industry, so that his association with an engineering society will date from the time he commences his engineering studies.

Dean Perley F. Walker, of the University of Kansas, in a written discussion stated as important the present sentiment in favor of making our professional societies a more vital counterpart of the engineering profession. The public-service aspect is being broadened and should be reflected in a declaration of principles. Dr. Walker directed his discussion to the consideration of the definite situation in The American Society of Mechanical Engineers and in its connection with other organizations. He outlined briefly the aims of The Federated American Engineering Societies and explained its method of procedure. He stated the aims of our Society to be as follows:

1 To benefit the individual member as a mechanical engineer
2 To develop and perfect the profession in our own field
3 To render public service through (1) and (2), and locally through professional activities and as groups of citizens specially trained and qualified to speak on questions of civic and industrial importance.

The local-section plan seemed to Dr. Walker to be capable of most pronounced development in new lines, inasmuch as local groups are in touch with civic and local enterprises. He suggested the appointment of more local committees to do active and fruitful work in conservation of resources and materials and in the development of local power resources, in the investigation of industrial development, and in coöperation with the Chamber of Commerce. He stressed the conduct of a service publicity program and prophesied a program that would increase immeasurably the public recognition of the engineer.

L. C. Marburg, consulting engineer, New York City, divided his discussion of Mr. Cooke's paper into two parts: First, the improvement in organization and policy of any engineering society; and second, the broad question of organization of the entire profession. Under the first heading, speaking of the A.S.M.E., Mr. Marburg called attention to the small percentage of ballots returned at elections and the small number of members that "ever get into some part of the play." He called attention to the great development of local sections and the future of the professional divisions which would undoubtedly increase many times the percentage of participating members. He seconded Mr. Cooke's suggestion that some professional divisions be limited to members doing active work. Mr. Marburg emphasized the opportunity offered by the local sections for the development of majority rule in the Society. Mr. Marburg also seconded Mr. Cooke's point that the fullest publicity of Society affairs is required.

In discussing the place of the engineering society in the commercial structure, he analyzed the purposes for which engineers are organized as scientific or technical and public. The public aims of the society are the attempts to render the service of the group to the community and incidentally to secure public recognition for the group. To successfully develop these aims, Mr. Marburg stated the need for an all-inclusive organization, as its influence would be in proportion to its size. He sounded a solemn warning that the engineers would lose their influence upon obtaining the reputation of being a set of highbrows. He pictured the difficulty of the adoption of an ideal type of organization because of the impossibility of realizing such a type in view of previous developments. Mr. Marburg reiterated as the most important statement of Mr. Cooke's that no organization of the profession will be satisfactory which does not provide for the greatest coöperation with other groups. Although a number of public problems today are in a large part engineering there are still other public problems which require the services of a group of experts for solution and it is with such groups that engineering coöperation must be played up. In closing Mr. Marburg emphasized again that the great opportunity which the engineering profession has for gaining influence by developing the ideal of service.

Mr. Cooke's Closure to the Discussion

Before the administrative and managerial problems of the profession and of the various organizations through which it functions can be profitably discussed, every effort must be made to visualize the enlarging field of the engineer. If one can get a sense of the desired crop, seed, soil and season become measurably fixed. Method is by no means negligible. But it is of the very first importance to decide on the goal towards which to strive. Otherwise united effort is impossible and even the strong press forward less ably than they would if the common objectives were fully determined.

There are many reasons for believing that as a group we are timorous in acknowledging the high purpose to which we are in-

vited through our education and experience and ability. Somehow we must learn to rise above the weakness inherent in our capacity for specialization. If possible, we must pay even greater tribute to the individual who through painstaking and unremitting toil digs out the true inwardness of a set of baffling facts. But also we must more and more insist that the completed task include the the relating of the result of our research to that whole scheme of living for the betterment of which the engineer is, we hope, becoming the master-architect.

So in all our planning as to method we should not only always have our objectives in mind, but keep them fluid so as to be capable of easy adjustment to meet the rising standards of action within the profession and changing needs without.

Any author would be pleased with the quantity and kind of discussion which this paper has received. Nevertheless it is a bit disappointing that so little of it suggests that to the engineer belongs the task of formulating definite programs "of creation and of construction, of stimulation of human effort and accomplishment." We should abandon the theory that we are assisting some other agency such as government or society. Both the responsibility and opportunity are wholly ours—are being literally forced upon us—almost literally in its totality.

With the task so defined the outstanding change called for is to get a larger number of members of the profession actually at our group work. The suggestion of Messrs. Coes and Gates for a personnel secretary seems altogether convincing. Such an official would only indirectly be interested in projects. His concern would be the maximum number of members making some contribution to the total volume of work. Then all through the formal and informal discussion of the paper has been emphasized the necessity for getting the young men both into the Society and at work as early as possible. If any one doubts how much this is needed and demanded, let him make a trip around the country visiting engineering organizations.

No such study as this can be altogether frank or very helpful without a suggestion as to one major danger which at every turn casts at least a shadow across our path, i.e., the influence of business as contrasted with engineering considerations. Because of this we must constantly make excuses both for things done and things left undone. No other profession in its development is quite so beset. We must constantly study the technique of steering clear of these influences and dangers and so set ourselves free to work at full liberty at our appointed task.

Vernon Kellogg says that while "the biologist does have certain positive knowledge of some conditions or factors that do help to determine the course of human life," it is also true that "the course of human life is partly determined by a set of conditions which are, so far, at least quite outside the special knowledge of the biologist. He can guess and wonder about them, just as other people do, but he has no right to claim that he knows about them." And so we engineers would rarely give people cause for offense if in our discussions we could frankly separate those matters which we have reasonably positive knowledge from those in which our judgment is no better than that of other well-opinioned folk.

In the end the machinery of administration and management will adjust itself to the ambitions and environment of the profession. The largest contributions to a better organization for the group will come from those engineers who, while insisting that as individuals we shall be afforded conditions most advantageous for good work, make effective public service the final test of our success.

Analysis of the positions held by the graduates of engineering colleges shows that only fifteen to eighteen per cent stay in technical work. The major portion enter widely different pursuits, although many seek positions of executive or managerial responsibility. This situation and the need of industry for trained intelligence to direct and operate its complex activities, has caused a number of engineering schools to establish new courses to educate executives. The Society of Industrial Engineers has also planned such a course. Prof. Collins P. Bliss, of New York University, has compared eight of these courses, and in an extended article in the July issue of *Managememt Engineering* shows their make-up and gives the time allotted to each general group of subjects and to each study.

GRAPHICS IN BUSINESS

THAT over 40 per cent of the members of The American Society of Mechanical Engineers are engaged in executive and administrative work is an indication that business requires its leaders to possess qualities which are developed by engineering training and experience. The demand is greater than ever for executives well trained in the analysis and evaluation of forces and influences that affect business. With its growth in complexity business is demanding a better knowledge of its significant facts. Much of the executive's time and effort is spent in the maintenance of a proper balance among the various activities and influencing factors of his enterprise. Stimulation of some and checking of others to meet the ever-changing requirements, call for numerous and frequent comparisons of these factors on which to base judgments and decisions.

The progressive executive realizes the necessity for improved methods for getting at the facts and for performing his own work. To an increasing degree he is seeking the aid of scientific methods to lighten his burden. Accounting and statistical reports have been used extensively to convey to him the facts of his enterprise, but these leave largely to him the burden of interpreting the figures in terms of relative movements of the various factors they represent. This requires him to retain in his memory large quantities of figures or to spend much valuable time in study and reference to tables and detailed data if he is to have a comprehensive knowledge of his intricate undertaking. Frequently he is forced to resort to short-cut formulas, often unsound, as a means of freeing his mind.

The presentation of the facts of the enterprise in vivid picture form, so that the interrelations and movements are quickly grasped and easily retained, is the function of modern business graphics. The relations and movements are the significant things to the executive, much more so than the absolute values of the different factors at any given time. The weakness of accounting and statistical presentations as distinguished from the graphic method lies in their static quality and the difficulty of conveying by figures an adequate conception of movement and interrelation. Considerable mental effort is required to obtain from a table of figures a clear conception of the direction and magnitude of the movement, for example, of the volume of sales of a product over a period of twelve months. A clearer mental picture can be quickly obtained without effort from a properly designed graph based on the same figures. When, however, it is desired to show the relations of these movements to those of similar previous periods or to predetermined quotas, the contrast between the use of tables and of a coördinated series of charts is vastly greater. Contact of executives with the earlier efforts to utilize graphic charts has lead many to view them with skepticism and not without reason. Frequently such charts were designed without any apparent regard for their comparability one with another, and as much study was required for their interpretation as for the corresponding tables. Study of these earlier efforts, from the viewpoint of executive needs with a realization of the importance of comparability of the charts in a given enterprise, has led to the development of a technique of chart construction which has greatly simplified their use. Many progressive concerns have appreciated the time-saving value of coördinated graphs as a management tool for the control of their activities.

Concurrent with the development of standardization in the construction of business charts has come a marked reduction in the cost of their production—an important factor when large numbers are used. While formerly it required men of considerable engineering and statistical ability to prepare reliable and practical business-control charts, it is now possible, by the employment of standard methods, inexpensive equipments and limited instructions, to prepare them with lower-paid clerks and stenographers and with great rapidity.

The "fact" type of mind is responsible for the perfection of this tool of business, and as the engineer becomes more familiar with fields of business and finance into which he is being drawn. there is every prospect that equally satisfactory solutions will be found for the many other problems such activities present.

W. Herman Greul.

SURVEY OF ENGINEERING PROGRESS

A Review of Attainment in Mechanical Engineering and Related Fields

Straight-Flow High-Lift Poppet-Valve Steam Engine

By J. Stumpf

Losses in steam engines are due to cylinder condensation, clearance space, throttling, friction, leakage, heat radiation, heat conduction and imperfect expansion. It is claimed that some of these losses are reduced in the engine about to be described.

The most characteristic element in this straight-flow or "uniflow" steam-engine cylinder shown in Fig. 1 is the very small high-lift nozzle-disk valve employed therein. It became possible to give this valve such small dimensions through the employment of a valve-gear shaft running at twice the speed of the main engine shaft. For an average cut-off of 10 per cent the eccentric motion with the camshaft running at a speed of the main shaft will give a maximum valve lift of h', while a valve lift h four times as great is obtained with a double speed of rotation by means of which the central angle α is increased to 2α. Because of this a double-seated valve of 200 mm. (7.87 in.) diameter can be replaced by a disk valve 100 mm. (3.93 in.) in diameter, with a corresponding reduction of clearance space and cylinder condensation area.

The valve motion is regulated from a layshaft running at twice the speed of the engine shaft by means of a cam, of which the lift and lead are regulated by means of a shaft governor, Fig. 3. The

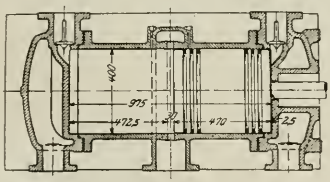

Fig. 1 Straight-Flow Steam Engine with the New Stumpf High-Lift Nozzle-Disk Valve

motion of the eccentric is transmitted to the disk valve by means of an intermediate lever and an angular lever located in the casing. The intermediate lever is made up in the form of an eccentric ring set on a rigid eccentric disk running at the same speed as the main engine shaft. The arrangement is such that when the main eccentric takes the position corresponding to the maximum valve lift

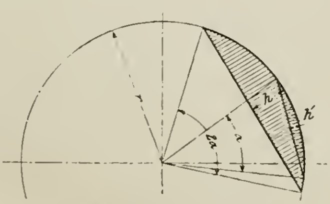

Fig. 2 Valve Diagrams

the auxiliary eccentric on the second lay shaft is in the opposite extreme position, thus producing an increased valve lift. When the main eccentric occupies the next similar position, the auxiliary eccentric reaches the opposite location so that the actions of the two eccentrics have to be subtracted from each other. The resultant valve motions are shown again in Fig. 4 by means of the Zeuner polar diagram, which emphasizes the extent of the valve opening resulting from the fact that the valve lay shaft runs at twice the speed of the main engine, and also shows the absence of all necessary motion of the valve in the opposite position. The linear lead remains the same. As a result of this arrangement it becomes possible to use small valves with a total clearance in the cylinder of between $^3/_4$ and 1 per cent and with an extremely small area of cylinder condensation surfaces. If it be assumed

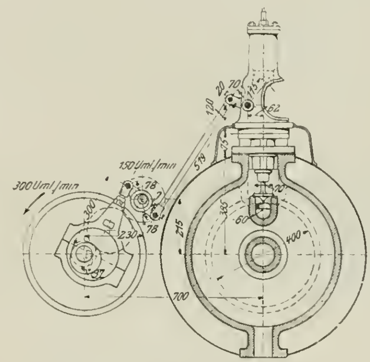

Fig. 3 Valve-Gear Drive

that these condensation surfaces are ideally small, that is, equal to twice the cross-section of the cylinder, it would appear that the additional cylinder condensation surface entailed by the use of the small high-lift nozzle-disk valve is only from 3 to 5 per cent thereof. It is claimed that this arrangement affects the reduction of cylinder condensation area in a most favorable manner, which

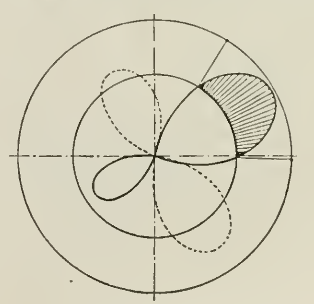

Fig. 4 Zeuner Polar Valve Diagram

is generally low in straight-flow steam engines. As regards this latter, reference is made to tests carried out on a straight-flow cylinder by Professor Nagel at the Dresden Polytechnic Institute. (The temperature diagram of these tests is reproduced in Fig. 5.) In that case only the cylinder head was provided with a jacket and the engine was operated with an extremely good vacuum. Notwithstanding this fact, during the exhaust stroke the temperature, as determined by a thermometer in the head, did not fall below 100 deg. cent. Because of the extensive temperature drop during the exhaust and because of the appearance of a very considerable percentage of moisture in the steam (as high as 20 per cent), the heat of the steam in the head was caused to flow with great energy into the rest of the steam still present in the cylinder. Of this heat practically none is lost in the exhaust. The piston

on its return stroke collects this overflow of heat by the compression of the remainder of steam to something like 2.5 to 3 atmos., corresponding to a clearance of about 3.3 per cent. The next compression occurs practically along the saturation adiabatic curve, which is joined at an angle by the superheat adiabatic curve and gives the startlingly high compression and temperature of 510 deg. cent. At the end of the admission the superheat expansion adiabatic curve joins on, and then abruptly the saturation adiabatic curve. This latter, in its last stages, is raised by the setting up of the flow of heat referred to above until the exhaust again causes temperature drop, which is, however, immediately opposed by the flow of heat from the cylinder-head steam.

However, when, by the use of the high-lift nozzle-disk valve

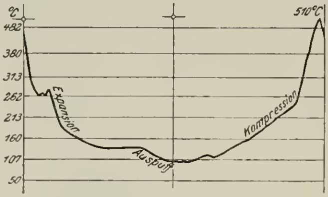

Fig. 5 Temperature Diagram
(*Auspuff* = exhaust)

the clearance is reduced from 3.3 per cent to something between $^3/_4$ and 1 per cent, the compression end pressure is raised correspondingly, resulting in a rise of compression and temperature of between 900 and 1000 deg. cent. In this connection Professor Nagel has established the surprising fact that in the same manner a final compression temperature with saturated steam is obtained

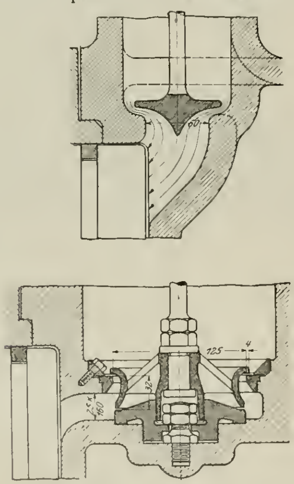

Fig. 6 Comparison of Two Kinds of Engine Valves with Same Area of Steam Passage: Above, High-Lift Nozzle-Disk Valve; Below, Double-Seated Valve

100 deg. cent. higher than with superheated steam, which is probably attributable to the higher heat conductivity of saturated steam.

If, however, these favorable heat conditions are combined with small cylinder condensation surfaces as becomes possible with the new high-lift nozzle-disk valve, it may be ultimately possible to do away with cylinder condensation entirely.

The upper part of Fig. 6 shows the new high-lift nozzle-disk valve operated by a lay shaft running at twice the speed of the main shaft, as compared with the double-seated valve of standard design below it, and also their relative dimensions. It is also claimed that the new valve is considerably simpler and cheaper both in manufacture and in installation. Short Abstracts of the Month

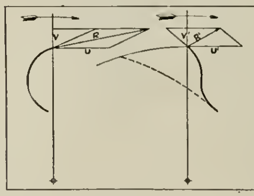
AIR MACHINERY

Centrifugal-Fan Design

Some Developments in Centrifugal-Fan Design, F. W. Bailey and A. A. Criqui. The authors claim that when multiblade forward-curved-blade fans supplanted the older type of straight radial-blade fans, two very good characteristics of the old blade fans were lost. One of these was the pressure curve which rose continuously with the decrease in capacity, and the other was the power curve which increased constantly with increasing capacity. In the forward-curved-blade fan the pressure curve drops or flattens with decreasing capacity within the working range of the fan, while the power curve has a more abrupt rise as the load increases, a combination which sometimes causes serious trouble in fan installations. The flat portion of the pressure curve makes the fan very sensitive to resistance variations, and if used at a capacity corresponding to this portion of the curve may make the fan run under or over the estimated capacity. This is particularly so if the friction of the system is slightly greater or less than was estimated or if an existing duct system is changed with the consequent change in resistance.

With a directly connected unit, when a fan which has an abruptly rising power curve runs above the estimated capacity, there is a decided danger of overloading the motor. With a motor-driven forward-curved-blade fan run at this critical point in its range, it is necessary to supply an excess of motor power with a probability of running the motor at reduced capacity and therefore reduced efficiency to guard against the possibility of the fan overloading. This represents a perpetual insurance payment when using a forward-curved-blade fan under these conditions. The flat or drooping portion of the pressure curve also causes trouble in double-width fans, or when two single fans blow into the same duct system, provided that the capacity comes within the range of this flat portion of the curve. If there is some difference in the resistance at the two inlets, which frequently happens, the capacity of one wheel will be reduced without any corresponding increase in pressure and this wheel then has no power within itself to regain the load, with the result that sometimes air will go in only one inlet of a double-width fan and the other wheel will merely churn the air in and out of its inlet.



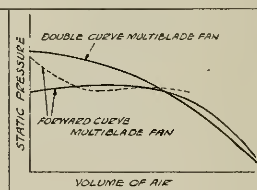


Fig. 1 Fig. 2

Fig. 1 Comparison of the Forward-Curved and the Backward-Curved Designs of Blades for Centrifugal Fans

Fig. 2 Comparison of Pressure Curves of the Forward and Double-Curved-Blade Types of Fans

A desirable combination of fan characteristics would be to retain the good features of the old radial-blade fan and at the same time have the high capacity range, insuring a small housing, together with the higher efficiency of the forward-curved-blade fan. During the past few years a new type of multi-blade fan has been developed which is said to combine these good features. This fan has blades which curve forward at the heel to meet the incoming air, but curve backward at the tip to discharge the air. Thus, while the blade of the forward-curved fan is a portion of the surface of one cylinder or one cone, the blade of the new backward-curved blade is formed from the surfaces of two cylinders or two cones, as shown in Fig. 1.

Fig. 2 shows the comparative pressure curves of a forward- and double-curved-blade fan. The latter has the continuous rising pressure curve, which, when capacity decreases, builds up a presssure to overcome the added resistance. In double-width fan, when one inlet is more restricted than the other, the tendency is for less air to flow through that inlet. In such a case the restricted wheel will build up a pressure to meet the added resistance and will thus retain its share of the load. As a result, a double-width fan of the double-curved-blade type will divide the load between the two wheels throughout the whole range of capacities and neither of the parts will simply churn the air as in the forward-curved-blade type.

The original article gives also curves showing the comparative static efficiencies of forward- and double-curved-blade fans and a comparison of their power curves.

The two types are not always competing. The forward-curved multi-blade fan is preferred where very high outlet velocity is required and noise is not objectionable. On the other hand, the double-curved multi-blade fan is essentially the medium-capacity fan and lends itself particularly to that class of ventilating work where very high outlet velocities are not needed or desirable; at the same time it is decidedly a higher-capacity fan than was the old radial-blade fan.

Double-curved multi-blade fans are inherently higher-speed fans than are those with forward-curved blades and this brings up the question of specifications. With the advent of the forward-curved-blade trouble was experienced from noisy fans, which was attributed to the higher speeds at which these fans ran. Engineers and architects therefore got the habit of writing into their specifications clauses which limited the speeds of multi-blade fans in order to insure large sizes or relatively slow-speed makes. As a matter of fact, the noise had very little to do with the speed of the fan. Double-curved-blade fans do not cause as much noise and at the same time must be run at high speeds. Therefore specifications which fix low speeds would practically prohibit the use of double-curved-blade fans. Theory of Hardening of Metals

The Slip-Interference Theory of the Hardening of Metals, Zay Jeffries and R. S. Archer. The authors define hardness as resistance to permanent deformation. Metals owe their hardness and strength to the attractive forces between their atoms. Metals, however, are also crystalline and are built up of atoms arranged in definite and repeating patterns. The regularity of the atomic arrangements gives rise to certain planes of weakness or low resistance to shearing stress.

When an external load produces on such a plane a shearing stress which exceeds the resistance of the crystal to shear on that particular plane, fracture of the crystal takes place. Fragments formed may or may not adhere to each other. If they do not the failure of the crystal is complete and it is said to be brittle, the plane of weakness being then known as the "cleavage plane." In the useful metals, more generally, the crystal fragments adhere and merely glide or "slip" over each other. In such a case the planes of weakness are called "slip planes."

Anything that serves to hinder slip is a source of strength and hardness. The hardening and strength of metals may be considered as due principally to interference with slip.

The authors express the relation between grain size and strength for pure metals by stating that the most simple source of increased hardness is grain refinement, which introduces slip interference at the grain boundaries due to the different orientations of the adjacent grains and especially in fine-grained metals to the disorganized or amorphous metal between the grains.

This theory is applied to the aging of duralumin, with respect to which the authors arrive at the conclusion that there is a certain average size of particle which produces maximum hardness, any size either larger or smaller causing less hardness. This is opposed to the generally held idea that a given amount of substance added to a metal produces the greatest possible hardening effect when it is in solution, that is, when it is in the highest possible state of dispersion.

The paper is too extensive to permit of making a complete abstract, and the following is taken from the summary prepared by the authors themselves:

Cold-working introduces slip interference by the fragmentation of the grains and the production of amorphous metal.

The hardness and strength of amorphous metal itself are due to the absence of the planes of weakness characteristic of crystals.

Slip within grains is opposed by the presence of a strong constituent at the grain boundary, provided that if the strong constituent is brittle, its shape and size are not such as to lead to effective weakness due to eccentricity of loading.

Effective hardening is obtained by slip interference within the grains, due to the presence of hard constituents uniformly distributed in the form of very fine particles.

It is not necessary that the hard constituent possess great adhesion for the matrix.

The effect of a given amount of hard constituent increases with the fineness of subdivision, reaching a maximum at an average particle size denoted by the term "critical dispersion." The critical dispersion probably consists of the smallest particles having the characteristic properties of the crystalline substance.

The order of magnitude of the diameter of such particles is probably about 10^{-7} cm. A higher degree of dispersion, particularly the atomic dispersion of solid solutions, is less conducive to hardness.

Corresponding to the maximum hardness at critical dispersion, there is a minimum in ductility.

Increase in the amount of dispersed substance produces increased hardness, but the brittleness also increases, so that there is a limit to the useful hardness and strength that can be obtained.

The amount of hard dispersed substance which produces the greatest useful strength increases as the size of particle increases.

The actual amounts of hard dispersed substances which produce useful results are from about 2 to 15 per cent by volume.

The only manner in which the high degrees of dispersion desired are produced consists in the limited decomposition of solutions, and in particular of solid solutions.

Martensite consists of a solid solution of carbon in very fine-grained alpha iron. The hardness is due chiefly to the grain refinement of the ferrite, but partly to the carbon in solution.

The tempering of martensite involves two changes: ferrite grain growth and the precipitation and growth of cementite particles. Ferrite grain growth causes progressive softening. The precipitation of cementite causes hardening, but the growth of the particles above the critical size produces softening. (*Chemical and Metallurgical Engineering*, vol. 24, no. 24, June 15, 1921, pp. 1057–1067, 11 figs., *tA*)

Wood-Reinforced Concrete

Concrete Reinforced with Wood, M. Levatel. Shortage and at times complete lack of steel during the war has given an impetus toward the use of concrete and, concurrently, a method for reinforcing concrete with non-metallic materials. The Italian engineer, Mario Viscardini, in the early part of 1918 produced concrete beams reinforced with wooden lattice work. Tests on these beams have shown that in general they behave practically in the same manner as similar beams reinforced with steel, but, of course, the numerical values of elastic limit and total strength are different. If wood-reinforced beams are overloaded they begin to crack, the cracks being larger and more clearly defined than in the case of steel-reinforced beams, but like the latter they can be easily repaired provided the stress did not exceed the elastic limit.

The same results have been obtained in tests made by Von Emperger and an Austrian commission, who have carried out an extensive

series of tests on wood-reinforced concrete beams and have found that the ratio of coefficients of elasticity of concrete and wood may be practically taken as unity.

One of the difficulties with wood reinforcement lay in the fact that in the first place the reinforcing elements had to be straight, and in the second place the stirrups could not be counted on to increase the adhesion between the concrete and the reinforcing elements. Among other things, it was found that tarring the wood reinforcing elements reduced the adhesion, whereas a wash of lime or cement, and in particular magnesia cement, over the wood reinforcing elements apparently increased the adhesion. Fur her tests by the Austrian commission have also shown that the proportion of wood to the total section of the beam should

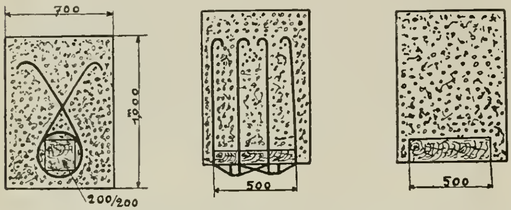

Fig. 3 Distribution of Wood Reinforcing Elements in Concrete Beams Recommended by an Austrian Commission

not exceed a certain percentage. In particular, beams of sections such as shown in Fig. 3 proved to be best.

In Germany a beam has been developed employing both steel and wood reinforcing elements (Fig. 4). In this the reinforcements which are in tension are of steel and those in compression are of wood, the latter being placed so that they form the top of the

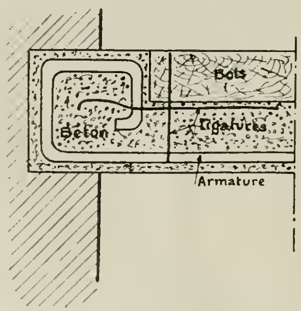

Fig. 4 German Steel-Wood Reinforced-Concrete Beam
(*Beton*, concrete; *Bois*, wood; *Armature*, steel reinforcement; *Ligatures*, tie pieces.)

beam and may be used for attaching boards, etc. Theoretically such a construction is complicated but it may have practical advantages.

One of the most interesting applications of wood-reinforced concrete has been made in the construction of the steamer *Linnea* in Sweden. This is a 700-ton vessel built essentially with the framework of an ordinary wooden ship and having concrete applied over it. The vessel has been in service on the Baltic and has apparently given satisfaction. (The original article describes an interesting method for launching it as concrete vessels cannot be conveniently launched with the usual gear.) (*L'Outillage*, vol. 198, no. 10, Mar. 10, 1921, pp. 283–284, 10 figs., *d*)

Tests of New Concrete Pressure Pipe. Description of tests recently carried out at Cleveland on a new type of reinforced-concrete pipe designed to withstand a pressure of 115 lb. per sq. in. (Failed at 255 lb. to the sq. in.) The chief feature of the design of the pipe is a longitudinally welded steel cylinder carrying a wire reinforcing mesh on the inside and outside, the whole being encased in concrete. The reinforcement is locked to the cylinder by strips of metal welded to its inside and outside faces. The ends of the steel cylinder are welded to sheet-metal hoops so formed as to take care of the expansion and contraction during the life of the pipe. The ends of the pipe are formed into the bell-and-spigot type, the sheet-metal hoops coming together in laying to form a lap joint on a bevel.

The pipe used in this test consisted of a steel cylinder 42 in. long, and 40 in. in diameter. Seven steel ribs $^5/_8$ in. by $^3/_{16}$ in. were equally spaced on the outside and inside of the cylinder and spot-welded to hold them upright. These ribs were punched with $^1/_2$-in. holes on $^3/_4$-in. centers to give a good bond with the concrete. They also acted as spacers for the reinforcing wire mesh.

The pipe was poured in steel forms from a rather wet mixture of Universal portland cement, roofing gravel with a density of 115 lb. per cu ft. and Pelee Island sand of a uniformity coefficient of 2.18 and an effective size of 0.22 mm. A mix of one part of cement, two parts of sand and four parts of gravel by volume was used.

In making the internal-hydraulic-pressure test, pressure was applied by means of a boiler test pump. At a pressure of 230 lb. per sq. in. horizontal cracks appeared in the two end sections. At 255 lb. per sq. in. a break occurred in one of the pipes. The rupture was directly caused by the failure of a large portion of the longitudinal lap weld which extended through the length of the main cylinder. In breaking, the concrete on both the inside and outside of the pipe was shattered.

An external pressure test was also applied in accordance with the method outlined by the American Society for Testing Materials.

From these tests it would appear that the wire-mesh reinforcing may be assigned a portion of the stress, perhaps the greater part of it, in which case it would seem advisable to increase the thickness of the concrete on the outside of the pipe and space the wire mesh at a somewhat greater distance from the steel cylinder. (*Concrete*, vol. 18, no. 5, May 1921, pp. 242–244, 4 figs., *de*)

Some Factors Affecting the Life of Machine-Gun Barrels, W. W. Sveshnikoff. The star-gage measurements made on six machine-gun barrels at various stages of firing indicate that when the life limit is reached, exhaustion is due to a combination of the abrasive action of the bullet and the abrasion by hot gases.

The author's experiments using the electric arc show that the rapid cooling (which is due to the large mass of cold metal near the highly heated inner surface of the steel) from temperatures near the melting point of the metal produces a martensitic layer. A similar layer is produced in firing a machine gun, indicating that the temperature conditions for development of martensite by the electric arc are similar to those in the gun under actual fire.

The selective hardening of the steel sets up surface strains, and the surface of the bore is readily cracked on account of the dimensional changes of the hardened brittle surface of the steel resulting from sudden changes in temperature between separate shots. The cracks originate at irregularities in the surface of the bore, attributable to the method of manufacture of the barrels. (*Abstract of Technologic Paper of the Bureau of Standards*, No. 191, *e*)

Comparative Tests of Steels at High Temperature, R. S. MacPherran. Data of tests made in the laboratory of the Allis-Chalmers Manufacturing Company to determine the comparative properties of various steels at high temperatures. The work was undertaken with the view to obtaining information as to the best material for use under operating conditions of 600 to 1000 deg. fahr.

Measurements were made with an electrically heated box in which the pyrometer head was practically in contact with the center of the test specimen. It was found that there is no one temperature at which all steels show a decided change in physical properties and that this point varies with the composition and treatment of the steel.

The maximum tensile strength for rolled carbon steel annealed,

and forged 3.25 per cent nickel steel annealed, occurs at about 600 and 650 deg. fahr.

The majority of the tensile-strength curves, especially those of heat-treated steels, drop sharply as the temperature exceeds 800 deg. fahr. The effect of nickel in small amounts is slight, but in large percentages it tends to lower the temperature at which tensile strength begins to decline. Nickel steel is the only steel examined where the ductility materially diminishes at the higher temperatures, monel metal bars, it is to be noted, however, behaving in the same manner.

Alloy steels containing chromium are less affected by rise in temperature than carbon steels, and it has been generally found that apparently the introduction of metals forming carbides tends to strengthen steels at high temperatures.

This, to a certain extent, bears out the results of tests on the comparative retention of physical properties in alloy steels at 1200 deg. fahr. or over by Leslie Aitchison, who finds the order of value to be tungsten, high-chromium and 3 per cent nickel. (Paper read at the meeting of the American Society for Testing Materials, June 24, 1921, abstracted through *Chemical and Metallurgical Engineering*, vol. 54, no. 26, June 29, 1921, pp. 1153–1155, 13 figs., *eA*)

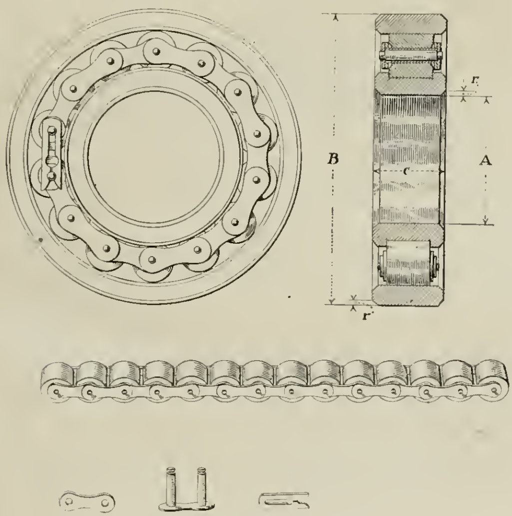

Fig. 5 Chain Roller Bearing

FUELS AND FIRING

A New Engine Fuel. At the meeting of the Society of German Chemists recently held at Stuttgart, Doctor Schrauth of the University of Berlin announced the development of a new fuel derived from naphthalene.

Naphthalene was used as a fuel even before the war, but the difficulty with it is that it is solid at ordinary temperatures and therefore requires preheating devices. It appears that now it has been converted into a liquid compound, tetrahydronaphthalene, having its boiling point at 205 deg. cent. (401 deg. fahr.) and a flash point of 78 deg. cent. (172.4 deg. fahr.) with the heating value of 11,600 calories per kilogram (20,880 B.t.u. per lb.), which makes it very desirable for high-compression engines of the aviation type. In ordinary automobile engines it can be used by mixing with materials boiling at lower temperatures such as gasoline—preferably in the proportion of one to one. Benzol may also be used instead of gasoline. It is stated that the new material, which, for the sake of brevity, is referred to as tetraline, has also a high dissolving power and can be used as a cleaning agent instead of gasoline. In this respect its low inflammability is of particular value. (*Aeronautics*, vol. 20, no. 398, June 2, p. 391, *g*)

MACHINE ELEMENTS

Chain Roller Bearing. Description of a new bearing placed on the market about a year ago by a British company.

The principal feature of the bearing (Fig. 5) is the employment of an endless and detachable chain as a separating and guiding means for the rollers. This gives certain advantages. Thus, the maximum number of rollers of the largest possible diameter are employed in each bearing, because the chain cage allows the rollers the minimum margin of clearance between one another without permitting them to come in contact; this eliminates separating pieces between the rollers and thereby provides an increased load-carrying capacity.

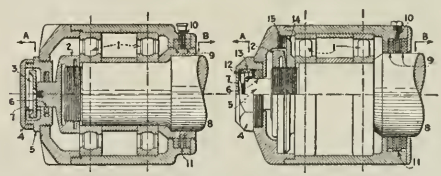
Each chain has a detachable link with spring-fastening clip which allows the chain to be unwrapped from the inner race for inspection, cleaning or replacement. This is an important feature with large drums where a standard pitch of chain cage of any length with any size of rollers can be simply wrapped around the drum without any special cage being required. (*The Practical Engineer*, vol. 63, no. 1788, June 2, 1921, pp. 347–348. 1 fig., *d*)

MACHINE PARTS

Ball Bearings on Electric Cars

Destructive Effect of Current on Ball Bearings of Electric Cars, Hilding Angstrom. Ball bearings on electric cars, in addition to great mechanical stresses, are also subjected to the destructive influences of current. The present paper (the author of which is connected with the Engineering Department of the Tramway System in Malmo, Sweden) is based on tests made by the General Electric Company and the Union Aktien-Gesellschaft, as well as on European practice.

From these tests it appears that a current as low as one ampere per square inch corrodes the housings and that a much smaller current is sufficient to damage the bearing metal. This is partly due to the fact that with ball bearings there is an almost metallic contact between the parts and no film of insulating oil intervenes.



Figs. 6 and 7 Journal Boxes Fitted with Auxiliary Contacts for Carrying Current

Fig. 6 At Left, Double Nut Arrangement

Fig. 7 At Right, Additional Pressure Provided by Spring

The flow of current from the trolley wheel downward is such that the various motor bearings and the gearing are in the path of the current with the ground. The action of the current is partly chemical but largely of the character of a weld, and it is chiefly the rupturing effect of the current that produces the welding action on the balls.

Figures in the original article show balls and bearings which have been thus destroyed. Of particular interest are dark stains on the balls which appear in the photographs. These were formerly considered as having been caused by acid in the lubricant or by shelling through fatigue.

Additional experiments have shown that the current distribution among the balls depends to a large extent on the load placed on them and that it is the rupturing effect and not the permanent current due to metallic contact that has the most damaging influence on their durability.

To prevent damage to the balls through the passage of electric

current some form of shunting device should be applied. The insulation of the outer ring of the ball bearing is possible but does not appear practical, as the repeated blows and shocks to which ball bearings are subjected would probably rupture or at least compress the insulating material and this would then produce additional stress in the ball bearings. A better way is to place a shunt or auxiliary contact arrangement outside of the ball- and roller-bearing casing. This shunt should have such a low resistance that it would practically exclude all transmission of current through the balls or the rollers.

A journal box fitted with N.K.A. disk bearings is shown in Fig. 7. This type of bearing has rollers which are self-centering, so that they tend to adjust their axis of rotation parallel to the axle of the wheel. The right-hand sides of the bearings shown in Figs. 6 and 7, which are marked *B*, show a current-transmission arrangement that can be applied to new bearing boxes. This arrangement consists of two brass rings which bear against the collar of the wheel axle. These brass rings also serve to support the felt rings 9, against which they are pressed by means of a spring. To provide a better contact and a path of less resistance for the current, the space between the brass rings is filled with graphite or mercury. The conducting power of graphite is about 10^{14} times as great as that of oil, and it is thus evident that the use of graphite facilitates the transmission of current to a high degree. This type of box provides a path of low resistance for the current and at the same time gives a very tight construction against the entrance of sand or dust from the outside. The left-hand ends of Figs. 6 and 7 marked *A* show a contact nut arrangement which can be applied to old ball- or roller-bearing boxes. In general this type of construction corresponds to that just described. In Fig. 6-*A* the current passes through the double nut at 4 and 5 to the graphite or mercury layer 7 and then to the contact disks 3, contact pin 2, and then to the axle of the wheel. In Fig. 7 *A* the nut arrangement is simplified somewhat and the tightening ring has been made more effective by the use of a spring bearing on a brass contact disk 7. The path of the current in this construction is through the contact nut 4, the contact spring 12 and the contact disk 7 to the contact pin 5 and then to the axle of the wheel. (*Electric Railway Journal*, vol. 57, no. 21, May 21, 1921, p. 941–944. 13 figs., *te*)

MACHINE SHOP

Cold Swaging

Cold Swaging. Swaging is used for work having a circular cross-sectional area and metal cannot be swaged by a swaging machine into any other sectional shape. Swaging is used mainly for producing small wire parts, sewing needles and instrument parts, and for tapering and reducing the diameter of tubing. [It may be added that swaging is also used in certain metallurgical processes as, for example, in the production of malleable tungsten wire by the Coolidge process—Editor.]

The article describes in particular the Dayton swaging machine which has a spindle speed of 300 r.p.m. and gives an average of 3600 quick short blows each minute.

Swaging increases the strength of materials, as has been shown by tests conducted in the physical laboratory of the Torrington Co. In six tests made there on cold-drawn steel wire ranging in diameter from 0.175 to 0.467 in. it was found that in all cases the tensile strength of the wire was increased by swaging and that the greatest gain in tensile strength occurred in the wire of the least strength before swaging. Furthermore, it does not appear that swaging affects unfavorably resilience or ductility of the material.

One of the most important applications of the swaging process is the reduction in diameter and tapering of tubes. Fire-hose nozzles and bicycle-frame parts in larger sizes and metal pencil shells and lightning-rod ends in smaller sizes are handled in this way. Swaging is also used in jewelry work and it is the only known process by which a gold-plated base-metal ingot may be reduced in diameter and still produce a plated article which will successfully withstand the acid test. It is stated that when a sample of wire of the sizes used in optical and jewelry trades is fractured and examined, the protective covering is so thin that there is no visible indication of an existing plate. On the other hand, case-hardened steel cannot be swaged as the hardened case fractures and crumbles.

Screw threads may be produced by swaging, the wire passing through the dies and the hollow spindle of the swaging machine to a reel at the rear. The threaded wire thus produced is not suitable for precision purposes but is extensively used for electrical and plumbers' supplies. Characteristic of the swaged thread is its accuracy in lead rather than in thread form. The form of swaged threads, however, is not excessively irregular.

The amount of reduction in diameter that can be successfully effected by the swaging process is largely an empirical matter. Small wire can be reduced the desired amount in one pass of the work through the dies, but on solid work which is large enough to withstand as great a reduction as $^1/_{16}$ in. a greater amount than this is not recommended in a single pass. This applies also to tubes if a mandrel is used, but tubing swaged without a mandrel will stand a greater reduction than this.

Some difficulty may be experienced in swaging tapered parts, particularly if the taper is abrupt, by the ends of the stock splitting, and there appears to be no remedy for this except to employ a preliminary lathe operation to break down the ends of the work. After this has been done, the ends may be successfully tapered and will not pipe or split. Where such abrupt tapers are produced, whether the stock is solid or tubular, some form of positive feeding device must be employed to overcome the axial thrust produced by the revolving dies. The Dayton swaging machine makes use of a rack-and-pinion feed for work of this type.

A high degree of accuracy can be obtained by the swaging process. In fact, swaging is extensively used for sizing wire, in which work a diameter can be readily and uniformly held to within limits of plus or minus 0.001 in., or even less for the smaller sizes. A corresponding degree of accuracy can be obtained when reducing the diameter by swaging, this accuracy increasing if anything, with the smaller diameters of work. One of the chief advantages claimed for the swaging process, as compared with machining, is the saving of stock effected. Besides saving stock and improving the physical qualities of the metal, many subsequent finishing operations, such as lapping and grinding, may be eliminated; also, the resilience of the metal is retained, as previously stated, even though it is increased in hardness and tensile strength.

The original article describes and illustrates various samples of swaged work. (*Machinery* (London), vol. 18, no. 453, June 2, 1921, pp. 257–261, 8 figs., *d*)

A New Sub-Press

Sub-Press for Blanking, Drawing and Punching, J. Blakey and J. Shankley. The sub-press shown in Fig. 8 is so designed that the plunger has not to be connected to the ram of the press and does not depend on the ram for its upward motion, because this is actuated by spring *O* under flange of extended buffer plug *K*. The base *C* can be fixed in any position on the press proper and over any existing clearance holes which can be utilized to get the punchings away, instead of having to force them back into the blanks. The cap *J* screwed on to body *G* for taking up the wear on the plunger babbitt bush *H* is made strong enough to withstand the pressure of the spring *O* when buffer *K* is forced down. The blanking and drawing die *D* has four punches *F* screwed into it. Die *D* is fastened to plunger *I* by four screws and two dowel pins as shown in sketch alongside. These punches *F* are a ground fit in stripper *E* (see sketch alongside), which in turn is spigoted into the bottom of piston *M*. It will be noted that punches *F* do not reach to the face of stripper *E*. As the plunger *I* descends along with plug *K* the stock is blanked by the outside diameter of *D* and inside of die *A*. Punches *F* do not come into operation until die *D* has commenced drawing and stripper *E*, piston *M* and spring *N* are depressed, thus preventing any distortion of the blank. Knockout *P* is a tee-sectioned ring and, as will be seen, is operated by four springs

equally spaced. The holes in die B for punches F are slightly tapered to the lower end for clearance after leaving a generous amount at the top parallel. A hole, shown dotted, is drilled in the center of piston rod M, which meets a small hole drilled to drill through its center to allow the air when piston is forced up to escape through the hole shown in plug L. The cup shown in section under plunger and in view in the upper left-hand corner was made from No. 17 gage sheet brass and was $2^1/_4$ in. in dia-

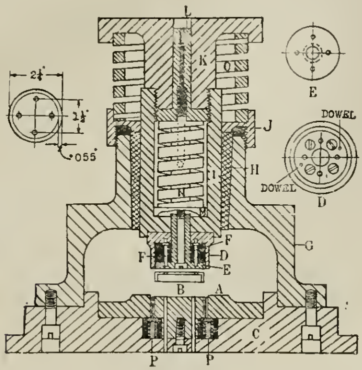


Fig. 8 Sub-Press for Blanking, Drawing and Punching

meter and $^7/_{16}$ in. deep, with four $^3/_{32}$-in. holes in the bottom. (*The Practical Engineer*, vol. 63, no. 1788, June 2, 1921, p. 349. 1 fig., *d*)

MILITARY ENGINEERING (See Engineering Materials)

POWER PLANTS

Boiler Corrosion

The Corrosion of Steam Boilers. As soon as steam turbines took their place as the standard type of prime mover for large powers, engineers hoped that the greater part of their boiler troubles would be over. The availability of the condensed steam, with its freedom from all scale-forming salts or traces of oil, for boiler-feeding purposes, opened up prospects of a new era in the boiler room. Experience, however, showed that a very soft feedwater involved troubles of its own, though just why soft feedwater attacks boilers is not quite certain. The opinion most commonly held is that with very soft water, corrosion is due to oxygen or carbon dioxide dissolved in the water. If this is so, it is desirable to avoid as much as possible the exposure of the condensate to the atmosphere and especially prevent all unnecessary agitation of the water in the presence of air. This led to the advocation of closed condensate systems. Another method consisted merely in bringing the feedwater into intimate contact with an extensive surface of unprotected iron, the idea being that the water should be allowed to satisfy its craving for iron by attacking metal specially provided for the purpose.

The engineer of a large London power station some time ago tried the experiment of filling his hot well with pieces of old boiler tubes. They were strongly attacked by the water, which was found to contain far less dissolved oxygen after passing over them than did the air-pump discharge. In the course of time, however, the action practically ceased on account of the protective coating of rust which was formed on the tubes. Mr. Kestner (paper before joint meeting of the Institution of Mechanical Engineers and Society of Chemical Industry, Mar. 4, 1921) secured continuous operation by reversing the direction of flow of feedwater. In another instance interesting results were secured by fitting some of the boilers with cast-iron economizers and the rest with steel ones. With the same feedwater, corrosion took place in the boilers with cast-iron economizers, but not in the others, the steel economizers themselves being attacked.

This would indicate that the corrosive capacity of feedwater is limited and may be eliminated by giving the water something to attack. In this connection it is stated that corrosion troubles were practically stopped in a certain steel economizer by filling it up with a mixture of lime and carbonate of soda, removing the safety valves and subjecting the mixture to a protracted boiling at atmospheric pressure.

The attacks are often of an erratic nature. Sometimes one boiler out of a group is attacked; at other times the main feed line along the boiler fronts is safe while considerable trouble is experienced with the smaller vertical connections of the boiler drums. These facts point to the probability that something in the composition of the steel may be a determining factor. Test by H. P. Gaze of the Central Electric Supply Co. would further indicate that ordinary commercial steel tubes supplied by the economizer makers suffer less from corrosion than charcoal-iron tubes, which would dispose of the contention that modern steel is a poorer metal in respect to corrosion than old-fashioned iron.

The author arrives at the conclusion, however, that there is more than a possibility that pitting is not entirely due to chemical causes but is rather of an electrolytic nature. A lack of perfect homogeneity in the steel would tend to cause electrical currents to circulate between different points, the currents passing through the body of the metal and returning through the water. Wherever such currents left the metal they would carry iron into solution and so eat away the surface. The suspension of a zinc plate in the boiler might not suppress these parasitic currents, as it could do nothing to alter the fact of a relative difference of potential between two points on the boiler shell.

The general conclusion arrived at is that until we can get metal which is chemically homogeneous or can devise some effective method of protecting the surface or possibly rendering it passive, corrosion can only be prevented by paying careful attention to the impurities in the feedwater. In modern plants these consist of little more than dissolved gases, which fortunately can be eliminated or neutralized without very great difficulty when once the danger of their presence is properly appreciated. (Editorial, *Engineering*, vol. 111, no. 2891, May 27, 1921, pp. 651–652, *tpA*)

Cross-Current Flow-Type Water-Cooling Tower. The water-cooling tower recently erected at the Government Electric Station at Dresden, Germany, is reported to be one of the largest in Europe. It has a capacity of 120 cu. m. (28,000 gal.) per min. A feature of this type of cooler is that the air and water do not flow on the counter-current principle, but the air enters the cooler horizontally while the water falls vertically. There is a central tower or "chimney," and the entire cooling system is external to the "chimney," surrounding it at the base. There are two important advantages. The interior of the tower (which is 120 ft. high) remains quite free from obstruction, and so a very free air draft is obtainable, with a constant velocity over the whole of the "chimney." The cooling plant consists of twelve independent compartments, any one of which may be isolated for cleaning and repairs. The water enters at a height of only 16 ft. above the foundations, thus requiring much less power for its elevation than with the high type of tower. The air current, entering the spray chambers horizontally, passes transversely through the falling water and exhausts into the central tower. Its passage is very much less impeded than if it had to force its way upward against a falling spray. Less substantial foundations are necessary and much less excavation. The floor space covered is, however, somewhat greater.

The whole of the cooling chambers are roofed by shallow distributing pans, which connect to the spraying devices below. These consist of short lengths of vertical piping, delivering on to spash plates rigidly connected to the latter. The splash laths are arranged below the plates, to cause the water to assume the form of films. This region of the cooling system is boarded in to prevent wind action blowing the water outside, and the formation of ice in the air entrances. Means are also provided for a measurement

of the water supply by troughs and weirs preceding the distributing system. (*Beama* [Journal devoted to the Interest of British Electrical and Allied Engineering], vol. 8, no. 5, May 1921, p. 418, *d*)

Spray Pond Formula. In connection with the formula for computing the temperature reduction which can be effected by a spray-nozzle installation, given in Mechanical Engineering, June 1921, p. 406, the following formula having the same purpose in view, is quoted from the latest catalog of the Cooling Tower Company (15 John Street, New York City):

$$T_1 = T - \frac{[0.5\,(T + 460) + 0.5(t_2 + 460)]^4 - (t_2 + 460)^4}{C \times 100{,}000{,}000}$$

Where t, t_1, T and T_1 are respectively the temperature of wet bulb or air, wet bulb, water before spraying, and water after spraying; $t_2 = (4t_1 + t)/5$ and $C = 5.1$ for average installations operating at $6^1/_2$ lb. pressure.

PUMPS

New Diagram for Determining Efficiency of Centrifugal Pumps

Determination of the Efficiency of Centrifugal Pumps, Allen F. Sherzer. The efficiency of a centrifugal pump is a function of the speed, head developed, and quantity discharged.

Since the efficiency of pumps cannot be reliably estimated solely on the basis of discharge, another method has been established in which the efficiency is made a function of the so-called constant of specific speed (N_s). This constant is supposed to include the effect of each of the variables.

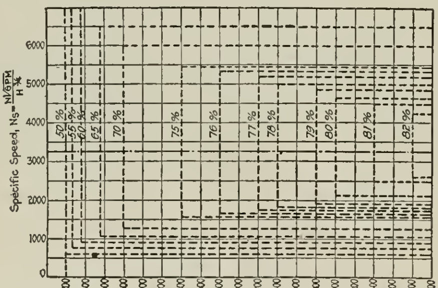

Fig. 9 Efficiency Contours for Centrifugal Pumps in Terms of Gal. per Min. and Specific Speed

The usual range of pumps have values of N_s from 500 up to about 5000, and the author shows by a curve that the efficiency increases quite rapidly with the specific speed until it reaches a maximum (N_s = about 3000), after which it falls off slowly. Moreover, he shows that the efficiency may be high over quite a range of specific speed and that, in general, there are two values of N_s corresponding to a given efficiency. Since neither capacity nor constant of specific speed alone give reliable indications as to efficiency, the author attempted to combine the two into a composite curve (Fig. 9), in which lines of equal efficiency are plotted on discharge in gallons per minute as abscissæ and values of N_s as ordinates. The lines of equal efficiency join to form a rectangle of equal efficiency. In other words, all points within the rectangle of equal efficiency are equal to or above the efficiency marked on the line enclosing them. By drawing a suitable number of these equal-efficiency lines intermediate values may be readily interpolated with sufficient accuracy.

The following instructions are given as to the use of this diagram: To make use of the diagram (Fig. 9), it is necessary to know the conditions of head, discharge, and speed under which the pump is to operate. Having these data, compute the value of N_s. Using this value of N_s as ordinate, and with the discharge as abscissæ, locate the point on the diagram in Fig. 9. In case this does not fall exactly on any of the lines shown, interpolate horizontally and vertically, which will give the probable efficiency with sufficient accuracy for all usual purposes.

An example may help to make this clear. Assume that a centrifugal pump is to be designed for a discharge of 600 gal. per min. against a total head of 120 ft. when operating at a constant speed of 1750 r.p.m., and that it is desired to estimate its probable maximum efficiency.

We first find that the value of $N_s = 1750\sqrt{(600)}/120^{3/4} = 1185$. Now turning to Fig. 9 and traveling up to the 600 G. P. M. line till we come to $N_s = 1185$, we find that the point lies at the lower left-hand corner of the 65 per cent rectangle and that its probable efficiency would be about 65 per cent or perhaps a little more. This value agrees quite satisfactorily with practical experience, but when used for power-estimating purposes it should be reduced a little for safety, as it frequently happens that the power required to drive the pump at its point of maximum efficiency is somewhat exceeded when discharging a greater quantity of water against a lower head, which may easily take place in any given installation. The accuracy of this method is necessarily limited by the accuracy of the data on which it is based, but as such were selected from various sources and include the results of tests on a great number of pumps, it is believed that it is at least representative of average practice. The method given in this paper may be readily applied to any type of pump and can be modified if necessary to accord with the experience of any who may care to make use of it. *Engineering News-Record*, vol. 86, no. 26, June 30, 1921, pp. 1114–1115, 3 figs., *epA*)

RAILROAD ENGINEERING

Double-Capacity Air Brakes on the Virginian Railway. The Virginian Railway, because of its predominant tonnage of bituminous coal which has to be hauled over comparatively steep grades, is especially interested in the question of the rapidity with which traffic of that character can be handled. In particular, on the section east of Princeton, long, heavy trains have to be handled down grades of 1.5 per cent, while near Elmore the trains have to be pushed up a 2.07 per cent grade.

This has materially affected the character of the rolling stock, with the result that today the Virginian Railway operates ten of the most powerful locomotives in the world and 1000 of the highest-capacity cars ever built, namely, 120-ton.

Incidentally these cars make the braking problem very serious, owing to the fact that their weight when empty is only one-quarter of the gross weight loaded, which is very desirable from an economical standpoint but makes difficult the handling of trains composed of such cars when loaded and going down grades and the return of long trains composed wholly of empty cars.

The problem of designing proper brakes in this case lay in the necessity to compensate for the great discrepancy in weight between empty and loaded trains. With single-capacity brakes the braking force developed is constant in magnitude but varying in its relation to the car weight. The usual practice has been to design the brake layout so as to provide the highest practicable percentage of braking forces on the empty car and then to accept whatever reduced braking ratio might be available for the loaded car. This was scarcely applicable to the conditions prevailing as stated above on the Virginian Railway, because it might not have provided a sufficiently safe control of the loaded trains on the down grades, or in long trains of empties might have resulted in severe shocks because of the high braking ratio of the empty train. In fact, the high-capacity cars on the Virginian Railway operated under so divergent conditions of loaded and empty trains that any attempt at a compromise between the two extremes would have resulted in unsatisfactory operation with either one or the other. The double-capacity brake equipment solved this problem, the layout being designed to provide for 40 per cent braking ratio (as against the usual 60 per cent) for an empty car, and also 40 per cent for the loaded car as against the usual average of 15 per cent. The additional force required to raise the braking ratios on loaded cars is obtained by the combination of an additional cylinder and increased leverage, a small load reservoir supplying the additional air.

When the equipment is set for empty-car operation the take-up

and empty cylinders, which are built into one structure with the small piston operating withinthe larger, operate as one 10-in. cylinder similar to the standard single-capacity brake. When the equipment is set for loaded-car operation the take-up cylinder piston first takes up the slack in the rigging and brings the shoes firmly against the wheels. Then the empty cylinder piston moves out a slight amount, its clutch gripping the notched push rod of the take-up cylinder piston, thus supplying additional force. Finally, as the brake-pipe reduction continues, the load cylinder piston moves out a slight amount, gripping its notched push rod and adding to the force already developed, through the connecting rods and levers. By this method of slack take-up and short travel of the larger pistons the volume of air required for a given application is reduced to a minimum.

The higher braking ratio necessary for the loaded car is obtained only when desired, and the equipment is manually changed for loaded car braking by the mechanism which shifts the change-over valve to its load position. Extensive tests have been made to demonstrate the efficiency and reliability of the new brake, one of the most spectacular of which was a test on a train consisting of 100 loaded 120-ton capacity cars, the brakes operating to the complete satisfaction of every one concerned.

Among those witnessing this test were four men who were present 35 years ago at the famous Burlington test of the Westinghouse air brake, which did much toward the universal acceptance of that type of brake on American railroads. (*Railway Review*, vol. 68, no. 24, June 11, 1921, pp. 885–894, illustrated, *d*)

SAFETY ENGINEERING

Influence of Mine Atmospheric Conditions on Fatigue. The effect of varying atmospheric conditions in mines may express itself in lowering the efficiency of the defensive mechanism of the human frame against disease. Such conditions may not be directly conducive to specific diseases, such as miners' tuberculosis, and yet may lead to a more feeble resistance against them. Such conditions are the creation of an undue amount of fatigue, the presence of minute quantities of irritant poisonous gases, such as carbon monoxide, nitrogen oxide, chlorine and cyanogen chlorite, a large deficiency of oxygen, or a large excess of carbon dioxide or nitrogen.

In this connection attention is called to the fact that in recent years there have been two remarkable changes in the opinion of competent authorities on the question of the relation of atmospheric conditions in mines to health. In the first place, contrary to what was formerly believed, the opinion came to prevail that much larger amounts than 0.20 per cent of carbon dioxide are tolerated by the human system. The author doubts, however, if this truly applies to cases where people have to breathe contaminated atmosphere for a very considerable length of time.

The other question on which medical opinion has lately undergone considerable change is the effect of high temperature and humidity on health. It was formerly held that while a wet-bulb temperature of 83 deg. fahr. might greatly diminish a laborer's output of work, it had no detrimental effect on his health. The experiments with air in motion, and, more recently, the introduction of the katathermometer, have shown, however, that conditions which induce undue fatigue when performing work must be detrimental to health. (Contribution by Sir Robt. Kotze to a paper by Dr. A. J. Ornstein and H. J. Ireland before the South African Institution of Engineers. *Journal of the South African Institution of Engineers*, vol. 19, no. 10, May 1921, pp. 202–204, *gp*)

SPECIAL MACHINERY

Aluminum Casting, John G. A. Rhodin. Discussion of dies, pressure casting and defects in aluminum castings.

As regards the design of dies, the author discusses dies constructed as individual units with all clamping arrangements, etc., made and adapted for the die, and dies made in sections to suit a universal holder, like the plates in a filtering press. In England the first method has been found to be best, as it gives the designer more freedom in selecting the position of the casting in the die, combining vertical and horizontal sections, etc.

Some information is given as to the design of such dies and it is stated that the principal thing is to start working out the die from the main section and find out the smallest number of others feasible. So far such dies have been used only for making pistons of various more or less complicated design. Fans, propellers, etc., have also been made in quantity, but they belong to the class of machine parts that work without accurate fitting. Resting parts of machinery of great variety have also been cast in built-up dies and their number was increasing rapidly when the industrial stagnation came.

One of the advantages of these self-contained dies is that they can be put bodily in a furnace for heating and taken out ready for immediate pouring. With regard to limits of dimensions the writer has seen castings with runs well over 2 ft. and weighing more than 25 lb. produced in dies of this type, such as gear cases and steering wheels for motor cars. On the whole, it is stated that die casting of aluminum by gravity feed was an almost unqualified success.

As regards the building up of a number of dies in the shape of plates capable of being handled in a screw press, the author is less optimistic. For very simple things the plan is satisfactory, but for complicated castings it is claimed to be hopeless. The plates were supposed to slide on bars, but the bars proved to be in the way of everything when the casting had to be removed. The dowel pins holding the outside plate of the die were found to have a tendency to stick on slight provocation, and, in general, while the whole thing worked occasionally, the universal application of the principle was abandoned.

The gravity method is not suitable for use on castings with very thin sections when high pressure must be used. Plunger pressure has proved successful with small castings of antimonial lead, but aluminum would spoil the fit of a plunger in no time. Because of this, the majority of pressure-casting machines are worked by compressed air.

The author tried a number of machines obtained from America in 1919 and says that with aluminum he had no luck. At the start really marvelous castings were produced, but in many cases the perfection was only apparent as they were full of gas bubbles under the skin.

His criticism of the design of these machines is that to begin with the permanent contact of the molten metal with iron is totally unnecessary and the same applies to the exposure of a large surface to the air. Furthermore, the gas in the castings is air which passes by hammer action through faulty design of the goose neck.

Generally, the author believes that the market for pressure die castings in England is confronted with serious difficulties not of a technical nature—purely the objection of the English public to articles produced from uniform patterns.

As regards defects in aluminum castings, blowholes are mentioned. They are apparently the result of an evolution of gas dissolved in the metal and are nearly always associated with overheating of the metal. Certain impurities like manganese, and to a lesser extent, iron, enhance the effect. (Aluminum and Its Alloys in Engineering, serial article, section 7, chapter 5; *The Engineer*, vol. 138, no. 3416, June 17, 1921, pp. 635–636, *p*)

SPECIAL PROCESSES

Development of the Bolt and Nut Industry, F. H. Chapin. The first machine-made bolt was produced in this country only 80 years ago, Micah Rugg, a country blacksmith in Connecticut, being the pioneer of the bolt industry in this country. Southington, Conn., can truly be said to have been the cradle of the bolt and nut industry in the United States.

The first heading machine was made by W. E. Ward about 1850 and used in making carriage bolts. In those days the $^5/_{16} \times 3$-in. carriage bolt sold for about \$33 per thousand and the bolt maker's wage was \$1 per day of 12 hours. Now, this same bolt is sold for about \$7.50 per thousand and the operators make from \$6 to \$8 per day for 10 hours' work.

It was only about the time of the Civil War that Wm. J. Clark of Milldale, Conn., brought out a method of forging carriage bolts from round iron. A little before that the manufacture of bolts by the cold forging process began.

The real development of the industry began with the advent of the method of making bolts from round iron.

As regards the industry as it is today, one of the most striking

features is the apparent total lack of standardization. Bolts and nuts are articles which function in such a simple manner that one would expect uniformity of types and sizes to come about practically automatically. As a matter of fact, the very opposite happens to be the case. The Upson Works of the Bourne-Fuller Co. alone have in their shops over 30,000 different dies for forging, trimming and threading, none of which are duplicates nor are considered entirely obsolete. (*The Iron Age*, vol. 107, no. 24, June 16, 1921, pp. 1609–1610, *g*)

British Seamless-Steel-Tube Manufacture

Seamless-Steel-Tube Manufacture. Review of the processes with especial reference to British practice, in particular such as employed by Accles & Pollock, Ltd., Oldbury, Birmingham, England.

Essentially the methods employed do not differ much from American methods. Great difficulty is said to be experienced in drawing tubes below $^7/_{16}$ in. diameter on a mandrel, and the usual practice adopted for finishing all sizes $^3/_8$ in. and under is by reducing the diameter only. (This process is called "sinking.") The tubes finished in this manner are not as consistent in quality as those finished on a mandrel and are not as strong.

Aircraft construction called for high-carbon and alloy-steel tubing, in particular chrome-nickel steel. At first trouble was experienced and mandrels and occasionally draw benches were broken through unsatisfactory annealing processes. These difficulties however, have been successfully overcome and chrome-nickel steel tubing is now being produced by the same plug-drawing process as used for mild steel, although the amount of reduction per draw is not nearly as great and care has to be exercised in annealing.

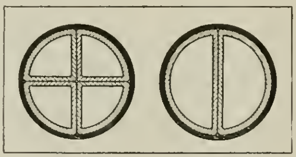

Fig. 10 Examples of Two Types of Reinforced Steel Tube

Reinforced tubes are also made. In the case of the flattened ends of struts on the rods it is quite common practice to insert a flat strip of steel, and rivet and solder it in position. This is not very satisfactory, however, as, unless some additional strengthening is provided, the tube is always weakened at the point where it changes its shape. A far more efficient method is that of inserting a tubular liner before flattening to extend some distance beyond the trapped portion. In Fig. 10 the tube to the left is formed by drawing a round tube over two D-sections. This particular combination was designed to withstand excessive vibration. The other combination is formed in the same manner but has four inner tubes. (*Engineering Production*, vol. 2, no. 35, June 2, 1921, pp. 675–679, 13 figs., *d*)

STANDARDIZATION (See Special Processes)

STREET RAILWAYS (See Machine Parts)

CLASSIFICATION OF ARTICLES

Articles appearing in the Survey are classified as *c* comparative; *d* descriptive; *e* experimental; *g* general; *h* historical; *m* mathematical; *p* practical; *s* statistical; *t* theoretical. Articles of especial merit are rated *A* by the reviewer. Opinions expressed are those of the reviewer, not of the Society. The Editor will be pleased to receive inquiries for further information in connection with articles reported in the Survey.

N.M.T.A. AND INDUSTRIAL EDUCATION

(*Continued from page 522*)

3 Many of those who do attempt to train have nothing even approximating a definite schedule for this work, and have not definitely determined responsibility for instruction and training as part of the duties of some person or group
4 Very few foremen are able to give instructions to a learner in a proper manner
5 Conditions in the various plants determine the type of training necessary.

It is the belief of the Committee that in the majority of instances, shops with one hundred or more employees should consider seriously the establishing of a training department. In the smaller shops the quota could very properly be trained in connection with the tool room or some special department. Each plant should have some individual in charge of, and responsible for, training.

The individual members of the Committee naturally have some preference for certain methods of training within their own establishments, but the Committee as a whole has not reached the point where it recommends any one system of training as being applicable to all plants; and when consideration is given to the size of our membership, the great differentiation in products manufactured, the vast territory covered, and the changing conditions within industry, it is unlikely that it will ever do so.

It is the opinion of the Committee that each plant should be considered individually, having a careful regard for the character of the product manufactured, the varying degrees of skill and intelligence required, the number of workers employed, the type of plant organization, the labor turnover, the method of recruiting new workers, the method, if any, of training now in use, the wage scheme, the plant spirit, the local conditions, and many more points which have a direct bearing on the question of training and education for the individual plant.

Too much stress cannot be laid upon the fact that no real permanent benefit can be expected from mere training along the lines of manual dexterity alone, unless such training is supplemented by a common-sense education of the worker, either by the employer himself or through his authorized representatives who carry to the worker the real policy of the employer.

This brings up the question of leadership in industry. The Committee believes that the only true leadership of labor must be furnished by the employers themselves, because they are the only class who are in a position to understand in a practical way both sides of the so-called labor problem. The fact that the employers have not made much progress in assuming the duties of leadership would seem to indicate that many of them do not yet fully realize that this part of their business is as essential as the efficiency of the worker.

GENERAL EDUCATION AND THE ENGINEERING PROFESSION

(*Continued from page 520*)

determination of the best procedure. There should be, furthermore, a large committee of leading educators in association with this agency to secure the necessary coöperation of all departments of society and business.

A ways and means committee of men from such organizations as the American Bankers' Association, American Defense Society, National Industrial Conference Board, Chamber of Commerce of U. S., National Civic Federation, Associated Industries of Massachusetts and New York and like bodies has been appointed to effect the creation of the above agency. The A.S.M.E. will be represented in association with other national bodies of engineers through the Engineering Foundation by Mr. W. W. Nichols, Chairman of its Committee on Education and Training in the Industries. Working with this committee will be an Advisory Committee on Education, already formed. We may therefore confidently predict that for the first time in America there will soon be a source of information and suggestion representative of a cross-section of American society and associated with all state and local interests that desire its services. The effect upon the nation should soon be manifest in the higher development of the individual by his better understanding of the forces about him.

ENGINEERING RESEARCH

A Department Conducted by the Research Committee of the A.S.M.E.

Research in Detroit and Vicinity

THE Research Committee of the Detroit Section of The American Society of Mechanical Engineers, composed of J. E. Emswiler, Chairman, Charles S. Glenn, C. J. Hirshfeld, J. C. McCabe and F. W. Steere, Secretary, has recently made its report to the Research Committee of the Society on the Survey of Research among the Industries of this district. The Committee takes this opportunity to express its appreciation and thanks for the work done by the Sectional Committee in making this survey, which included correspondence with one thousand firms.

The report will be submitted to the Society for action, but it is advisable at this time to give the following conclusions made from the results of the survey:

1 Only 14. 3 per cent of the firms canvassed have any apparent interest in the subject of research.

2 Only 2.2 per cent of the firms canvassed are doing research work that they consider of general interest to the profession.

3 Of those firms doing research work of Class A, the kind of work that appears to be receiving most attention is along the line of improved methods of producing, heat-treating, and machining steel and alloys, a kind of work upon which seven firms reported.

The kind of work reported upon by the next largest number of firms, viz., 5, is that of automobiles and accessories.

4 As is to be expected, most of the general research work is reported by the larger organizations, which indicates a commendable attitude on the part of firms that are financially able to do it, and emphasizes the importance of all means that can be employed for pooling the research interests of engineering industries, such, for example, as the recently established Engineering Research Department of the University of Michigan, and the more general facilities of the A.S.M.E. for the free exchange of ideas.

5 There appears to be a considerable amount of material in this Section's jurisdiction available at once, and in the near future, for publication in the Society's Journal, MECHANICAL ENGINEERING.

Research Résumé of the Month

A—RESEARCH RESULTS

The purpose of this section of Engineering Research is to give the origin of research information which has been completed, to give a résumé of research results with formulas or curves where such may be readily given, and to report results of non-extensive researches, which, in the opinion of the investigators do not warrant a paper.

Apparatus and Instruments A6-21. RULING SCALES BY LIGHT WAVES. See *Light A2-21.*

Cement and Other Building Materials A9-21. TESTS OF BUILDING PARTITIONS. Tests are being made on partitions made of brick and other building materials when exposed to high temperature for six hours. The test specimens are 11 ft. by 16 ft. in area and 8½ in. thick, supported by a heavy steel frame so that they can be swung into place and form the side of an oil-fired furnace. The temperature of this furnace is increased according to a predetermined program and the tests continued for six hours. Observations are made at various parts of the partition for temperatures and on the distortion caused by heating. The cold side of the panel is investigated for temperature to determine whether or not this is high enough to ignite inflammable material. Observations are also made to determine whether or not cracks develop. A number of tests are being made each month and engineers, architects or other interested parties are invited to visit the Bureau of Standards to witness these tests. Exact dates may be ascertained by correspondence. Bureau of Standards, Washington, D. C. Address S. W. Stratton, Director.

Fuels, Gas, Tar and Coke A10-21. COKE BREEZE AND BITUMINOUS COAL AS FUEL. John Blizard and James Neil of the Bureau of Mines have made Report 2244 on the Value of Mixtures of Coke Breeze and Bituminous Coal as Fuel for a Hand-Fired Boiler. Tests were made at the request of the Chamber of Commerce of Pittsburgh, Pa., to determine the steam value of the mixtures and to determine whether or not mixtures would give off objectionable quantities of smoke. The tests were made on a No. 60 Smith boiler with grate bars containing air spaces ½ in. wide and occupying 52 per cent of the total grate area, and also with air spaces $^1/_4$ in. wide and occupying 31 per cent of the grate area. The Smith boiler contains a mixing chamber for the purpose of smoke prevention. The fuel consisted of coke breeze and Pittsburgh run of mine coal. The breeze was of two sizes, one passing through a $^3/_4$-in. to 1-in. screen and the other through a ½-in. screen. The coke breeze weighed 48 lb. per cu. ft. and gave heating values between 9500 and 10,000 B.t.u. per lb. The coal contained 10 per cent ash and 3 per cent moisture and had a heating value of about 13,000 B.t.u. per lb. With equal weights of coal and breeze the heating value of the mixture varied from 11,300 and 11,800 B.t.u. per lb. The tests showed that mixtures of coarser coke breeze with Pittsburgh coal gave less than one half the smoke given out by the Pittsburgh coal alone. It produced 20 per cent less steam and required a stronger draft. The finer coke breeze gave about the same amount but required a much stronger draft. Bureau of Mines, Washington, D. C. Address H. Foster Bain, Director.

Fuels, Gas, Tar and Coke A11-21. COAL-DUST HAZARD. Coal-Dust Hazard in Industrial Plants is the title of report 2246 by L. D. Tracey to the Bureau of Mines. The report discusses the various causes of explosions and ignition and concludes with a number of observations to be used in designing apparatus for the use of pulverized coal. Bureau of Mines, Washington, D. C. Address H. Foster Bain, Director.

Heat A10-21. PYROMETRY. Technologic Paper No. 170 on Pyrometric Practice from the Bureau of Standards is now available from the Superintendent of Documents, Government Printing Office, Washington, D. C. Price 60 cents a copy.

Light A2-21. RULING SCALES BY LIGHT WAVES. The Bureau of Standards has made for and delivered to the Brown and Sharpe Company a 6-in. scale, the rulings of which have been made by using the light waves from a tube containing neon (wave length = 5800 to 6600 A). No intermediary standard was used. Bureau of Standards, Washington, D. C. Address S. W. Stratton, Director.

Lubricants A1-21. EFFECT OF PARAFFIN WAX UPON VISCOSITY. The Effect of Crystalline Paraffin Wax upon the Viscosity of Lubricating Oil is the subject of Report 2249 by E. W. Dean and L. E. Jackson to the Bureau of Mines. Tests were made on 5-gal. samples of Pennsylvania crude petroleum by distilling at various temperatures and determining the viscosities of various fractions which were subsequently subjected to treatment which removed successive percentages of paraffin wax by chilling and filtering. The conclusions are:

1 Changes of content of paraffin wax up to a maximum of approximately 9 per cent have been shown to cause negligible variation of viscosity of the fractions cut between 250 deg. cent. and 275 deg. cent. and 276 deg. cent. to 300 deg. cent. at 40 mm. reduced pressure.

2 The value of the Bureau of Mines method for determining viscosity of vacuum-distillation fractions is not affected apparently by the fact that paraffin wax is not separated from the products that are tested.

3 Variations of paraffin wax content have negligible effect on viscosity.

4 Present results are not sufficient to prove a general rule.

Bureau of Mines, Washington, D. C. Address H. Foster Bain, Director.

Properties of Engineering Materials A5-21. ALUMINUM SOLDERS. The Bureau of Standards has recently completed tests on aluminum solders and the results will be found in the revised edition of Circular 78 on Solders for Aluminum. No solder has been found which will stand the corrosion test, although fused zinc chloride solders will stand corrosion for the greatest length of time. Bureau of Standards, Washington, D. C. Address S. W. Stratton, Director.

Transportion A1-21. FIBER BOXES. In the manufacture of fiber boxes made of laminated or corrugated paper board, silicate of soda has been used to form the adhesive substance employed. Silicate of soda may be so made that a small difference in concentration produces a large change in viscosity. Solutions may be prepared which change from a sirupy liquid to a solid by the loss of as little as 10 per cent of the moisture. This behavior is closely related to the ratio of alkali to silica in the silicate solutions. In practice silicates containing more than three molecules of SiO_2 to each molecule of Na_2O are used. The absorption of moisture from the solution by the paper board produces the setting. The bond strength exceeds 500 lb. per sq. in. The silicate of soda does not attract vermin, being a mineral product. Philadelphia Quartz Company, Philadelphia, Pa. Address James G. Vail, Chemical Director.

B—Research in Progress

The purpose of this section of Engineering Research is to bring together those who are working on the same problem for coöperation or conference, to prevent unnecessary duplication of work, and to inform the profession of the investigators who are engaged upon research problems. The addresses of these investigators are given for the purpose of correspondence.

Fuel Utilization B2-21. Texas Lignite. An investigation on the method of handling Texas lignite under hand-fired boilers. University of Texas, Austin, Texas. Address Prof. Hal C. Weaver.

Heat B19-21. Heating and Ventilation. Prof. R. W. Noland is investigating the steam traps and vacuum valves used on radiators, utilizing new and original equipment for this purpose. Address Dean A. A. Potter, Purdue University, Lafayette, Ind.

Heat B20-21. Heat Transfer. A determination of constants of heat transmission for new materials as well as the study of surface and humidity effects. Address Prof. A. J. Wood, Pennsylvania State College, State College, Pa.

Hydraulics B4-21. Hydraulic Jump Below Overflow Dams. A state of conditions determining the formation of the jump, its control and its utilization for useful purposes. Address Prof. S. M. Woodward, State University of Iowa, Iowa City, Ia.

Internal-Combustion Engines B6-21. Mixture Requirements. Prof. G. A. Young and C. S. Kegerreis have investigated the effect of speed on mixture requirements of an internal-combustion engine. Previous experiments showed that load has no effect on mixture ratio. The effect of speed is investigated in this research. Address Dean A. A. Potter, Purdue University, Lafayette, Ind.

Lubricants B4-21. Viscosity. Experimental Study of the Variation of Absolute Viscosity of Oils with Temperature is the subject of a thesis by A. R. Albouze. This will cover a large number of different oils with temperature variation from 60 to 320 deg. fahr. and incorporate all published data of other investigators. Address Prof. W. F. Durand, Leland Stanford Junior University, Stanford University, California.

Metallurgy and Metallography B9-21. Ingot Casting. A study of the difficulties in making ingots of nickel and monel metal which are similar to those encountered in making steel ingots. These difficulties are due to the peculiar relation between metals and their oxides. Address John F. Thompson, Manager, Technical Dept., International Nickel Company, 43 Exchange Place, New York.

Properties of Engineering Materials B2-21. Constantan. A study of the possibility of producing copper-nickel metal directly from the furnace, using different thermoelectric specifications to eliminate subsequent selection and testing of wire. Address John F. Thompson, Manager, Technical Dept., International Nickel Company, 43 Exchange Place, New York.

C—Research Problems

The purpose of this section of Engineering Research is to bring together persons who desire coöperation in research work or to bring together those who have problems and no equipment with those who are equipped to carry on research. It is hoped that those desiring coöperation or aid will state problems for publication in this section.

D—Research Equipment

The purpose of this section of Engineering Research is to give in concise form notes regarding the equipment of laboratories for mutual information and for the purpose of informing the profession of the equipment in various laboratories so that persons desiring special investigations may know where such work may be done.

State University of Iowa D1-21. The College of Applied Science of the State University of Iowa is just putting into use its recently completed Hydraulic Laboratory. This includes a concrete flume 130 ft. long and 10 ft. wide, so arranged that it can be supplied with water to a depth of 7 or 8 ft.; a small laboratory building in which hydraulic turbines up to 51 in. in diameter can be installed for testing and experimental purposes, under a head not exceeding 10 ft. A water supply is constantly available which is never less than 100 to 200 cu. ft. per sec. and during most of the year exceeds 1000 cu. ft. per sec. In conjunction with the laboratory a recording register is in use in the Iowa River and a cable gaging station across the river, which is about 300 ft. wide at this point. It is planned to have ultimately a full equipment available for studying the rating of current meters for all kinds of weir experiments and investigation of hydraulic apparatus and machinery. Address Prof. S. M. Woodward, State University of Iowa, Iowa City, Ia.

University of Pennsylvania D1-21. The Equipment of the Mechanical Engineering Laboratory of the University of Pennsylvania contains the following apparatus:

Boilers, Etc.

A 90-hp. B. & W. boiler for 200 lb. per sq. in. working pressure with Warren Webster open feedwater heater with Lea recorder and Wainwright closed feedwater heater. Foster independently fired superheater.

Steam Engines, Condensers, Etc.

- $10^1/_4$-in. by 24-in. Corliss with surface condenser
- 8-in. by 16-in. Porter-Allen with surface condenser
- 7-in. by 13-in. by 10-in. Reeves compound with surface condenser and air pump
- $6^1/_2$-in. by 10-in. Buckeye with surface condenser and air pump
- 6-in. by 6-in. Harrisburg with surface condenser
- 8-in. by 10-in. Kingsford vertical unaflow with condenser
- Two 8-in. by 10-in. Metropolitan
- 7-in. by 7-in. Fairbanks
- Extra 515 sq. ft. surface condenser for miscellaneous testing
- 8-in. by 10-in. Ames engine.

Turbines

- 15-hp. DeLaval single-stage turbine and reduction gear
- 25-kw. Kerr turbine direct-connected to d.c. generator with condenser and air pump
- 22-hp. Terry turbine direct-connected to 4-in. Worthington centrifugal pump.

Compressors

- 8-in. by 8-in. by $9^1/_4$-in. by $14^1/_4$-in. by 8-in. two-stage air, duplex simple steam-driven Ingersoll-Sergeant air compressor with air-measuring tanks and surface condenser
- 6-in. by 11-in. by 6-in. two-stage air compressor belt-driven by 10-hp. motor
- No. 4 Sturtevant air blower belt-driven by 5-hp. motor.

Pumps

- 8-in. by 12-in. by 7-in. by 12-in. Worthington duplex compound direct-acting pump
- $7^1/_2$-in. by $10^1/_4$-in. by 10-in. vertical duplex steam pump
- 5-in. centrifugal pump direct-driven by 20-hp. motor
- 4-in. American volute pump direct-driven by 20-hp. motor
- $1^1/_4$-in. Tacony three-stage centrifugal pump direct-driven by 2-hp. motor
- 4-in. by 4-in. Deming triplex pump direct-driven by 3-hp. motor.

Hydraulic Motors

- 12-in. Doble wheel
- 12-in. Pelton wheel.

Hydraulic Measuring Apparatus

- One V-notch weir
- Two 10-in., one 15-in. and one 18-in. contracted weirs
- Two 2-in. venturi meters with manometers
- Two 5-in. venturi meters with manometers
- Numerous hook gages, tanks, platform scales and manometer for measurement of discharge from orifices and nozzles.

Stationary Gas, Gasoline and Oil Engines

- $9^1/_8$-in. by $17^1/_2$-in. Otto with suction producer and scrubber
- 6-in. by 9-in. Warren single-cylinder horizontal
- $7^1/_2$-in. by 14-in. Springfield single-cylinder horizontal
- 8-in. by 10-in. Westinghouse two-cylinder vertical
- 10-in. by 16-in. Burger single-cylinder horizontal
- $7^5/_8$-in. by $10^7/_8$-in. Foos single-cylinder horizontal
- 6-in. by $6^1/_2$-in. Mietz single-cylinder horizontal
- 5-hp. Thermoil (semi-Diesel)
- 5-hp. New Way (air-cooled).

Automobile and Airplane Engines, Etc.

- 4-in. by 5-in. four-cylinder Teetor
- $3^1/_2$-in. by $5^1/_4$-in. six-cylinder Continental
- $3^1/_4$-in. by 5-in. eight-cylinder Peerless
- 80-hp. LaRhone airplane engine
- 150-hp. six-cylinder Hall-Scott airplane engine
- 8-cylinder Hispano-Suiza airplane engine
- 12-cylinder Liberty airplane engine
- 75-hp. Sprague electric dynamometer with test stand
- Fan dynamometer
- Detroit hydraulic dynamometer
- American balanced diaphragm high-speed indicator
- Midgely optical high-speed indicator
- Schultz manograph.

Fuel and Gas Testing

- Two analytical balances
- Complete apparatus for proximate coal analysis
- Emerson bomb calorimeter
- Parr bomb calorimeter
- Junker calorimeter for gas and liquid fuels
- Two Orsat flue-gas apparatus
- Two Franklin flue-gas apparatus
- Hempel gas-analysis apparatus
- Open-cup flash-point apparatus
- Closed-cup flash-point apparatus
- Saybolt viscosimeter
- Westfals balance
- Electric furnace.

Material Testing

- Two 30,000-lb. Riehlé tension and compression machines
- Two 30,000-lb. Olsen tension and compression machines
- One 50,000-lb. Olsen tension and compression machines
- One 60,000-lb. Riehle torsion machine
- One 6,000-lb. Thurston autographic torsion machine.

Conference on Present State of Knowledge of Properties of Steam

AT an informal conference held in Cambridge, Mass., on June 23, 1921, at the instance of Mr. Geo. A. Orrok,[1] fourteen gentlemen were present, including several representing important users of steam, several makers of steam tables, several experimental experts in the heat-measurement field, and the chairmen of the three A.S.M.E. committees most directly interested.

The following facts were presented as to the range and reliability of the experimental data on which the steam tables now in use are based:[2]

Vapor pressures are apparently satisfactorily known over the whole range up to the critical point, except for some slight uncertainty below 70 deg. fahr. This uncertainty might perhaps trouble designers of cooling towers or of air-conditioning apparatus. Otherwise it is unimportant. Incidental checks on the vapor-pressure curve are always desirable, but not at present greatly needed.

Our knowledge of the heat of the liquid is most unsatisfactory. Between 32 deg. fahr. and 212 deg. fahr. the great need is for a better determination of the mean heat unit now commonly used as the fundamental heat unit of our tables. Both the mechanical equivalent of the mean heat unit and its ratio to the heat units ordinarily employed in precision calorimetry are uncertain by at least two-tenths of one per cent. While this uncertainty seems small from an engineering point of view, it appears in so basic a place that it can hardly be ignored. The corresponding fundamental units of electrical engineering are experimentally reproducable to at least ten times this accuracy.

Above 212 deg. fahr. there are only two determinations of the variation of the specific heat of water with temperature, one of which is seventy-two years old and the other sixteen. Both are, for various reasons, unsatisfactory.

The density of water under the pressure of its saturated vapor is fairly well known up to 600 deg. fahr. It is not an important quantity in engineering computations. Further measurements might therefore be considered unnecessary, were it not for the fact that substantially equivalent work must apparently be done in any case in connection with the calibration of the apparatus for other highly important work.

Latent or total heats of saturated steam have been directly measured up to about 380 deg. fahr. (181 lb. gage saturation pressure) with probable errors, which, although small from the percentage point of view, are nevertheless large from the point of view, for example, of the turbine designer. This sort of measurement is very difficult to make with the desired accuracy, and total heats along the saturation line are best determined by other means.

In the superheated region three sorts of measurements can be made, namely, measurements of the specific volume, measurements of the specific heat at constant pressure, and measurements of the Joule-Thomson "cooling effect," each being determined as a function of pressure and temperature over any desired range of the variables. Theoretically, any one of these kinds of measurement, if made with sufficient accuracy, would suffice for the computation of a complete steam table (provided that various functions which appear as constants of integration were known, as is now largely if not wholly true). If, then, two of these quantities are measured, there is a check on the experimental work. If all three are measured, there is a triple check. Considering the difficulty of the precise experimentation in the whole field, such a multiple check is highly desirable.

On volumes, the Munich experiments are generally regarded as the best available. Their range is from atmospheric pressure up to about 150 lb. gage, and from saturation to a superheat that is sometimes as low as 20 deg. fahr. and is never as high as 100 deg. fahr. Their accuracy is good enough from the practical point of view, but neither accuracy nor range is sufficient for any check on rates of change of either specific heats or Joule-Thomson coefficients.

On specific heats, there is the large group of Munich experiments published in three instalments and from about half an atmosphere absolute (saturation temperature about 177 deg. fahr., to about 270 lb. gage (saturation tempe ature about 413 deg. fahr). As to temperature, these experiments cover, at all the above pressures, the range from saturation to about 725 deg. fahr., and up to about 100 lb. gage they run up to 1100 deg. fahr. This range covers admirably present commercial conditions, but should be supplemented at the high pressure end to provide for the pioneer development work now contemplated by many designers. Except near saturation, the accuracy of these experiments is probably good enough for our present needs, although there is still room for personal judgment in fitting smooth curves to the experimental points. There are also some experiments by Thomas. At least near saturation, they are seriously affected by priming. Callendar apparently believes that this can be corrected for, and much dependable information obtained from this work. The more generally held opinion seems to be that this work requires confirmation.

On the Joule-Thomson cooling effect, there are the classical papers of Grindley, of Griessmann, and of Peake that have been discussed by everybody for about fifteen years. These experiments do not show unmistakably even the sign of the pressure coefficient of the Joule-Thomson effect, to say nothing of the magnitude of this coefficient. And when plotted against temperature, the band of points that these experiments yield is from 15 to 40 per cent wide. There is also an isolated va'ue by Trueblood which is too lonesome to be important. And finally, in his recent book, Callendar casually introduces a dozen values, mostly at comparatively low pressures, "selected so as to cover the experimental range as evenly as possible," from a set of observations "most" of which "were taken between 150 deg. and 120 deg., and between 15 and 50 lb. pressure." The reliability of this work still rests solely on his previous reputation, since he has published no details.

The present experimental situation can, then, be summed up as follows: Vapor pressures and possibly liquid volumes are well enough known for the present; superheated specific heats are fairly well known except at pressures above 270 lb. gage; specific volumes are known directly only below 150 lb. gage and at low superheats; latent and total heats of the vapor are known directly but not entirely satisfactorily up to about 190 lb. gage; above that pressure they are not known directly at all; Joule-Thomson coefficients (from which total heats can best be determined) are scarcely known at all above 50 lb. gage; and finally, our knowledge of the heat of the liquid and of the fundamental heat unit on which the whole table is based is most unsatisfactory.

In the light of these facts, the conference agreed unanimously that the chief need at present is not so much for further discussion or study of the existing data, or even for an agreement among those interested in a "standard" table, as for more and better experimental work, especially at high pressures. They therefore outlined the appended experimental program which, in its present form, is in some ways a compromise between the best that could be wished for and what the apparatus and personnel in sight seem fitted to give. For example, the proposed work on the Joule-Thomson effect is limited to 600 lb. and 600 deg. fahr. because that is all that can be hoped for with the apparatus now available at Harvard without extensive changes and considerable delay. On the other hand, no limits are set to the range over which vapor and liquid volumes are desired, because the apparatus now available at the Massachusetts Institute of Technology is good up to the critical pressure, and at least up to the critical temperature. On the other hand, no limits are set to the range of the proposed experiments on liquid and vapor specific heats, because, although a considerable part of the development work on the necessary apparatus has already been done at the Bureau of Standards in connection with their ammonia work, the steam apparatus will have to be modified to cover any part whatever of the temperature range desired, and the efficient range of the new apparatus cannot be wholly foreseen until some work has been done on designing it. It was understood at the conference that the Bureau work could probably be pushed to 600 lb. and 600 deg. fahr., and perhaps even further in one or both directions.

The Present State of Knowledge of the Properties of Steam

THE report of a conference which was held at Pierce Hall, Harvard University, in Cambridge, Mass., on June 23, for the consideration of the present state of knowledge of the properties of steam, is published on page 553 of this issue.

Geo. A. Orrok

During the last five years, while the divergences of the steam tables in this country have been small, we have been hearing of developments in England both in the superheated range and also with regard to supersaturation. Abstracts of a number of articles on the subject have appeared from time to time in Mechanical Engineering, including Martin's article on the new theory of turbine design (page 784, September 1918) which deals with supersaturation. Callendar's new steam tables which have been recently brought out differ widely from the more commonly used tables of Marks and Davis and of Goodenough, and these differences are of the order of one part in one hundred or larger. (A review of Callendar's book was published on page 259 of the April issue.) The minor differences between Marks and Davis and Goodenough have been covered in a paper by Professor Heck which was presented at the last Annual Meeting of the Society and was widely discussed.

It was brought out at the Cambridge conference that our heat unit is accurately known only to about one part in 300, while our electric units are known to at least one part in ten thousand. It appears that the range from 80 to 350 deg. fahr is fairly well covered. but our determinations are from fifteen to seventy-two years old and there are many minor differences. Pressures up to 160 lb. are fairly accurate, but our points in the superheated field are apparently doubted by more than one authority, the actual point and trend of the curves being problematical. Various explanations have been offered for these divergences, the latest theory being that supersaturation is responsible for most of the discrepancies.

Meanwhile, the march of progress is accelerating. Power plants using steam at 250 lb. pressure are common; 300 lb. is not unusual and at least one plant is operating at 400 lb. gage pressure. The use of even higher steam pressures is projected, and in the near future we may expect to see the use of 800 to 1000 lb. as common as is 250 lb. today. Steam temperatures are only limited by the nature of our materials of construction and 700 to 750 deg. fahr. are common, while superheater manufacturers are talking of 800 to 1000 deg. fahr. It is apparent that at the present time most of our data above 360 deg. are extrapolated and the location of the curves is a matter of personal opinion rather than of scientific fact.

The conference agreed that the only thing to do was to secure more data in the higher and lower ranges, carrying the work as far as possible but restricting it so that the results would be available in a reasonable time. From the nature of some of the apparatus available it is thought that the upper limits may be extended to 600 lb. and somewhere between 600 and 700 deg. fahr. The determination of the Joule-Thomson coefficient will determine the trend of the curves in the upper ranges, and the amount of extrapolation will be greatly reduced.

The conference expressed the belief that it will be possible to so conduct the various lines of experimentation that three independent checks on the pressure-temperature-volume relation will be obtained and many of the mooted questions which now appear in the discussion of this subject can be definitely settled for all time with an accuracy suitable to the purpose in view. The Council of The American Society of Mechanical Engineers has approved this program and the Research Committee of the Society will be charged with its administration. The results of the conference have attracted widespread interest among the manufacturers and users of steam apparatus. Geo. A. Orrok.[1]

Opportunity for Engineering Service

ABOUT February 20, 1921, New York experienced a heavy fall of snow. On Washington's Birthday, the 22nd, I was at home trying to take advantage of the holiday to catch up with my work. My attention, however, was continually distracted by the efforts at snow handling and removal going on outside. There seemed to be little planning behind the work, and much of the effort was misdirected and often harmful. Emergency work can never be highly efficient, and while this particular snowfall was handled better than had ever before been done in New York, it nevertheless left much to be desired.

Acting largely upon impulse, I sat down and dictated a letter to Mr. Calvin Rice suggesting that the Society take up the problem at a special meeting. In due time I received a reply from Mr. W. S. Finlay, Jr., saying that a meeting of the Metropolitan Section had previously been planned to be held in the fall for the consideration of the snow problem. This meeting has now been scheduled for September 23, and I have been asked to present the subject briefly in the columns of Mechanical Engineering to induce fellow-members to give it serious thought and demonstrate how much can be accomplished in solving our public problems by arousing widespread interest on the part of our Society members.

Few people realize what a vast weight and bulk is represented by a 12-inch snowfall. Possibly in New York this amounts to as much as 1,000,000 tons and more than 300,000,000 cubic feet. Calculations showing the quantity and weight will be both interesting and valuable.

The known cost of snow handling is very large,and the unknown cost due to lack of prompt removal and the impediment to traffic is perhaps much larger. Actual figures on the known cost and calculations on the unknown cost will be interesting and valuable. Listing all of the methods of handling or removing snow, and then giving comparative costs, will also be valuable.

For instance, snow can be scraped from narrow streets into nearby squares or parks. Much of it is now hauled away by trucks and wagons. It is so bulky that un'ess a special body is used a 10-ton truck with a body designed for construction material would probably be filled when it had a ton of snow on it. Query: How much weight can be loaded on a truck, and how shall we adapt the ordinary truck or wagon body to carry snow?

Special loading devices are being experimented with. Sug-

[1] Consulting Engineer, N. Y. Edison Co.

gested improvements will be in order for these devices, also for trucks with self-loading attachments.

Water is often used to flush the snow into the sewers. Except under special conditions this probably represents a very costly method of snow removal. Actual and calculated costs by this method will be valuable.

New York is using motor-driven scrapers. Suggested improvements of these machines will be valuable.

To create interest in the subject I gave to the newspapers a copy of my letter to Mr. Rice, and received a great many letters on the subject—some from engineers, but mostly from non-engineers. These letters showed how little the layman knows about the physical constants that underlie the problem—and I am sorry to say that some of the engineers showed little knowledge of the value of these physical constants and the quantities to be dealt with.

For instance, a general line of attack seems to be that of melting the snow to water and running it into the sewers. If New York has 1,000,000 tons of snow to deal with for every 12-inch snowfall, this would require greatly in excess of 10,000 tons of coal—and would still leave much labor expense to handle the snow, as it would be difficult to melt it in place.

I made a number of suggestions in my letter to Mr. Rice of methods of handling our snow, but as the space here available will not permit very extended treatment, I will have some of the correspondence printed and sent to the headquarters of the Society so that any one especially interested in the subject can send for copies.

I think the most promising suggestion I was able to make was to briquet the snow, thus compressing it to a much smaller volume and permitting it to be put in piles having vertical sides and thereby taking up very little of the width of the street. Several inventors have already gone to work to design automatic briquetting machines that will gather up the snow, briquet it and stack it. One engineer connected with a machinery-manufacturing concern of this character told me that he had worked out a preliminary design, and had made some preliminary figures on speed and cost, and that he was inclined to think that snow handling by briquetting and stacking would prove so efficient and economical that it would supersede all other methods and therefore would be applied universally.

The officers of the Metropolitan Section want to demonstrate that the big public problems can be best solved by the engineer, and to do this they must bring out at this meeting means for dealing with our snow problem vastly better than anything we now have. Will you help?

Henry L. Doherty.

A.A.A.S. Plans Engineering Activity

Mr. L. W. Wallace has recently accepted the appointment as secretary of the Engineering Section of The American Association for the Advancement of Science for the term ending with the Toronto Meeting of the Association in December.

The American Association for the Advancement of Science is organized in sixteen sections, such as mathematics, physics, medicine, astronomy, engineering, etc., each of which holds its own session at the annual meeting of the Association. The American Society of Mechanical Engineers, and the other leading national engineering bodies are affiliated with the Engineering Section and nominate annually two honorary councilors. Dr. Ira N. Hollis and Prof. Robert W. Angus are the nominees this year.

Mr. Wallace, Secretary of the American Engineering Council of The Federated American Engineering Societies, which organization embraces the whole profession, will bring to his new work a keen understanding of the needs of the engineering profession in developing contacts that will add to it dignity and usefulness. The activity of the Engineering Section of the American Association for the Advancement of Science leading up to the convention in Toronto next December should be productive of greater understanding, not only between the branches of pure and applied science but between the various branches of engineering represented in the Engineering Section. In other words, another link has been added to the chain of engineering and professional coöperation.

To achieve the true ideal of service the engineering professions should have many professional alliances. Although the engineer may occupy a strategic position of service to the public, he can accomplish little alone. The true ideal can be attained only by coöperation of the broadest nature.

Frederick F. Sharpless Elected New Secretary of the Mining Engineers

At a meeting of the Board of Directors held on June 24, Frederick Fraley Sharpless, mining engineer and metallurgist, educator and editor, was unanimously elected secretary of the American Institute of Mining and Metallurgical Engineers, to succeed Bradley Stoughton, whose resignation was noted in our July issue.

Frederick F. Sharpless

Mr. Sharpless is a native of Pennsylvania and a graduate of the University of Michigan, class of 1888. He was professor of metallurgy at the Michigan School of Mines for five years and American representative of the Consolidated Mines Selection Co., Ltd., London, for fourteen. He has traveled widely throughout the United States, as well as in Alaska, Canada, Mexico, Central and South America, Asia and Africa.

In addition to having been a member of the A.I.M.E. for thirty-two years, Mr. Sharpless holds membership in the Mining and Metallurgical Society of America and the Institution of Mining and Metallurgy of London. His varied experience and wide travels make him especially well fitted for the office.

War-Invention Disclosures

Since the armistice there has been a flood of information published as to war inventions made by the various military agencies of the United States, and this flood is still continuing.

In Great Britain a similar policy was followed at first, but as time goes on less and less information is being published, considerable secrecy being maintained in regard to really important things. Thus, for example, while a very large volume of data is available in print as to the production of military gases by the Chemical War Service of the United States Army, comparatively little is known as to what similar agencies have done in England.

Only driblets of information regarding the military secrets of the French Army have become available through French sources, and next to nothing has been made public by the Germans as to their technical achievements during the war.

A New Management Magazine

The first issue of management engineering, styled "The Journal of Production," appeared July 1. It is published by the Ronald Press Company, under the direction of Leon P. Alford, Vice-President A.S.M.E., a technical editor of experience who served in that capacity on the *American Machinist* for nine years and on *Industrial Management* for two years. Mr. Alford is assisted by E. W. Tree, formerly associate editor of Mechanical Engineering.

The July number contains articles on a number of the fundamentals of management engineering, such as, The Training of Foremen, Responsibilities of Management, Educational Courses in Management Engineering, Cost Accounting, and Storeskeeping. The leading article is a contribution from Edwin S. Carman, President A.S.M.E., entitled The Pioneer Spirit in Engineering.

Each of the articles is indexed according to the Brussels classification of the Dewey decimal system, and Harrison W. Craver, director of the Engineering Societies Library, presents a method

by which this system of classification may be utilized to advantage by the engineer in connection with his own library.

Dr. Philip B. Woodworth New President of Rose Polytechnic Institute

Rose Polytechnic Institute has selected as its president Dr. Philip B. Woodworth, to succeed Dr. C. L. Mees who resigned in 1919 upon the completion of twenty-seven years of service.

Dr. Woodworth was graduated from Michigan State Agricultural College in 1886 with the degree of B.S.; he received the degree of Master of Engineering in electrical engineering from Cornell University in 1890. The year of 1891–92 he spent as a student of engineering and science at the University of Berlin. In 1920 his alma mater conferred upon him the honorary degree of Doctor of Science. Dr. Woodworth began his teaching experience in the Michigan public schools before entering college; in 1892, when he returned from abroad, he became professor of physics and engineering in Michigan Agricultural College. Seven years later he became professor of engineering in Lewis Institute, Chicago, and later dean, which position he held until 1917 when he was called into Government service. There he was successively executive secretary of the National Council of Defense and regional director for the North Central States, in charge of vocational training work for enlisted men.

In addition to that gained through his teaching Dr. Woodworth has had wide experience in engineering. He served as designing and consulting engineer for the Piatt Power Co. in the construction of a dam at Lansing, Mich., and for three years as superintendent of operation. He was also managing superintendent of the Lansing Street Railway for two years. He has been retained in the capacity of expert consultant by the Chicago surface lines, the Peoples Gas, Light and Coke Co., the Chicago Elevated Railway, the Chicago Telephone Co., the Commonwealth Edison Co., the Western Electric Co., the Aeolian Co., New York, the Christensen Air Brake Co., Milwaukee, and numerous other smaller corporations. The greater part of the work was done under the firm name of Rummler, Rummler & Woodworth, attorneys and engineers.

Dr. Woodworth is the author of numerous technical and education papers and of a textbook on Engineering Principles. He is a member of the American Institute of Electrical Engineers, the Western Society of Engineers, the Society of Automotive Engineers, the Society of Industrial Engineers, the Engineers' Council (Masonic organization) and also of the Chicago Electric Club.

Francis Bacon Crocker Dies

Francis Bacon Crocker, eminent electrical engineer, died on July 9, 1921, at his home in New York City, at the age of sixty-one. Born in New York City, he was educated in the city schools and attended the School of Mines, Columbia University, from which he was graduated in 1882. Later he organized the school of electrical engineering at Columbia and served as its head for twenty years, when he retired because of ill health. His most important contribution to the electrical industry was the commercial motor, the first of which was put into use in 1886. This was produced in conjunction with Charles G. Curtis and Schuyler S. Wheeler as the C. & C. Co. and later the Crocker-Wheeler Co., of which he was a director at the time of his death.

Professor Crocker was one of the two American delegates to the International Electrotechnical Commission in London, and at its most important session was able to insure the standardization necessary to make worldwide electrical manufacturing successful. For this work Lord Kelvin described him as one of the world's two greatest electricians. During the war Professor Crocker acted as adviser to the Naval Consulting Board. With Peter Cooper Hewitt he developed the first successful helicopter in this country, which was taken over by the Government and put into manufacture shortly before the armistice came. He was also the author of a number of standard treatises on electric lighting and electrical machinery.

Samuel Storrow Webber

Samuel Storrow Webber, life member of The American Society of Mechanical Engineers since 1880 and manager from 1902 to 1905, died on April 27, 1921. Mr. Webber was born in Springfield, Mass., on March 31, 1854. When sixteen years of age he entered the drafting department of the Rogers Locomotive Works, Paterson, N. J. He was next associated with the Blood Manufacturing Works at Manchester, where he became acquainted with the practical side of the business. As mechanical engineer, Mr. Webber accompanied several expeditions for gold dredging in California and South America. He was connected with the Trenton, N. J., Iron Works for twenty-five years, retiring in 1914.

Samuel S. Webber

Mr. Webber became a member of the Society in 1880. He was a member of the Engineers' Club of New York.

James Prentice Sneddon

James Prentice Sneddon, general superintendent of The Babcock & Wilcox Co., Bayonne, N. J., died at the Johns Hopkins Hospital, Baltimore, on June 11, 1921. Mr. Sneddon was born on July 7, 1863, in Wishaw, Scotland. He came to this country at the age of thirteen and for three years attended the public schools of St. Louis, Mo. At the end of that time he entered the employ of the Carbondale Coal & Coke Co., Carterville, Ill. So successful was his work there that he was given charge of the construction of a forty-mile railroad for the company. Convinced that he possessed engineering ability, he returned to St. Louis to serve an apprenticeship as machinist with the Rankin-Fritsch Foundry & Machine Co.

Toward the end of his apprenticeship he was sent to Indian Territory as erecting engineer, and later to the Tennessee Brewery at Memphis to install power-plant and refrigerating equipment built by his company. When the plant was put in operation he was asked to assume charge and for the next four years held the position of plant engineer. In 1889 he became master mechanic for the Pittsburgh Plate Glass Co. at their works in Crystal City, Mo., with charge of installation of all equipment. Four years later the Rankin-Fritsch Foundry & Machine Co. tendered him the position of general manager with stock interest, which he accepted, assuming full responsibility for the design and building of their line of Corliss engines and other equipment for power plants.

In 1899 he became superintendent in charge of manufacturing of the Stirling Boiler Co., Barberton, Ohio. In 1906 the company had enlarged greatly and the boiler department of Aultman-Taylor Co. was absorbed, at which time Mr. Sneddon became general manager, in charge of all manufacturing, of the Stirling Consolidated Boiler Co. In 1907 a further consolidation was made with The Babcock & Wilcox Co., and Mr. Sneddon assumed the position of general superintendent with headquarters at Bayonne, N. J. Later his duties were broadened to include the vice-presidency of the Pittsburgh Seamless Tube Co., a subsidiary of The Babcock & Wilcox Co., with full charge of all manufacturing operations for these associated companies.

The war interrupted this service in 1915, at which time he was technical adviser to the British Mission in the U. S. During the following year he was a member of the staff of J. P. Morgan & Co., export department, when they were buying and furnishing supplies for the Allied Forces. When the United States entered the war he returned to his regular duties and continued his war activities in manufacturing shell forgings, boilers and tubes for the U. S. Navy Shipping Board and essential industries.

Mr. Sneddon was a member of the Engineers' Club of New York, the Machinery Club, and the Masonic Order. He became a member of the Society in 1891.

ENGINEERING RESEARCH

(*Continued from page 552*)

E—Research Personnel

The purpose of this section of Engineering Research is to give notes of a personal nature regarding the personnel of various laboratories, methods of procedure for commercial work or notes regarding the conduct of various laboratories.

International Nickel Company E1-21. The Research Department of the International Nickel Company is located at the Orford Works at Bayonne, N. J. The department occupies over 5000 sq. ft. of floor space. It is under the direction of Dr. P. D. Merica. The work of the department is along a number of lines including the following:

The possible use of non-metallic compounds such as black nickel sulphide, black nickel hydrate and nickel chromate as paint or printing pigments. Compounds of nickel oxide with zinc oxide for body colors in ceramic ware and solid nickel compounds for fungacides. Many nickel compounds are not thoroughly known by chemists. Investigations are made of their properties for use in the arts.

The laboratory is also working on the properties of monel metal, constantan, soda glass with approximately 30 per cent of sodium oxide, and black glass for table tops. A study is also being made of the properties in production of ingots in casting. Address John F. Thompson, Manager, Technical Department, International Nickel Company, 43 Exchange Place, New York.

Massachusetts Institute of Technology E1-21. The various laboratory facilities at the new plant of the M.I.T. have been increased materially since the original installation. The Road Materials Testing Laboratory has been increased and the laboratory dealing with heat treatment has been doubled in size, while the Metallographic Laboratory under the immediate charge of Dr. Fay has been made much larger. Prof. Cowdray has been specializing in the cellular structure of wood and has found that there is a great demand for information regarding this matter. Address Prof. Edward F. Miller, Massachusetts Institute of Technology, Cambridge, Mass.

Ohio State University E1-21. The Engineering Experiment Station is about to issue a bulletin on the Economy in Liquid Fuel Utilization by Professor Norman. Professor Judd is continuing his work on pulsating flow in pipes. Theses regarding the strength of fillets, friction in bearings and on the strength and elasticity of indicator cords have been completed, although they are not ready for publication. Address Prof. W. T. Magruder, Ohio State University, Columbus, Ohio.

Pennsylvania State College E2-21. The Experiment Station of the Pennsylvania State College will be engaged during the summer on investigations of heat transfer, using a new hot plate for determining constants of new materials and studying surface and humidity effects. Dr. P. Nicholls of the Franklin Manufacturing Company will work in the laboratory during the summer. The laboratory will also investigate oxy-acetylene welding and will make a preliminary study of fuels for house-heating boilers. Address Prof. A. J. Wood, Pennsylvania State College, State College, Pa.

State University of Iowa E1-21. During the next twelve months Prof. Floyd A. Nagler and two research assistants, appointed and paid by the University, will devote half of their time to the conduct of original research in the recently completed hydraulic laboratory belonging to the University. It is expected that this research will deal largely with fundamental principles regarding the flow of water over weirs. These studies will take such special direction as may seem of most immediate practical use to the engineering profession. The laboratory will welcome suggestions from engineers as to immediate needs in this direction. Address Prof. Floyd A. Nagler, State University of Iowa, Iowa City, Ia.

F—Bibliographies

The purpose of this section of Engineering Research is to inform the profession of bibliographies which have been prepared. In general this work is done at the expense of the Society. Extensive bibliographies require the approval of the Research Committee. All bibliographies are loaned for a period of one month only. Additional copies are available, however, for periods of two weeks to members of the A.S.M.E. These bibliographies are on file at the office of the Society.

Petroleum, Asphalt and Wood Products F2-21. Recent Articles on Petroleum and Allied Subjects. The Bureau of Mines issued each month a bibliography on Recent Articles on Petroleum and Allied Subjects prepared by E. H. Burroughs. Bureau of Mines, Washington, D. C. Address H. Foster Bain, Director.

University of Pennsylvania E1-21. Among the investigations made at the University of Pennsylvania during the past year have been those relating to the efficiency of operation and mechanical construction of hoisting apparatus and the efficiency and conductivity of pipe. Address Prof. R. H. Fernald, University of Pennsylvania, Philadelphia, Pa.

CONFERENCE OF PRESENT STATE OF KNOWLEDGE OF STEAM PROPERTIES

(*Continued from page 553*)

The conference also discussed at some length the question of supersaturation, and its bearing both on turbine design and on the form of future steam tables. Some gentlemen felt strongly that an experimental study of this question should be added to the proposed program. All agreed that this would be highly desirable if practicable. No such action was finally agreed upon, however, partly because a definite suggestion worthy of unanimous approval as to just what ought to be attempted in a laboratory or experimental plant failed to materialize, and partly because the personnel question seemed difficult. The whole matter was therefore reluctantly laid aside for the present. It deserves thoughtful consideration by all who may by any chance be able to contribute to the desired solution.

REPORT OF THE CONFERENCE

We the undersigned, having met in informal conference in Cambridge Massachusetts, on June 23, 1921, have discussed at some length the present situation with respect to steam tables in the United States.

We feel strongly that it is of great importance to all users of steam in the United States that the properties of steam should be known with reasonable accuracy at pressures considerably higher than those at which any reliable experimental data are at present available.

After canvassing the situation we believe the following experimental program should be undertaken:

1 The specific heat of water should be determined with the greatest possible accuracy up to the boiling point of water at atmospheric pressure for the more accurate determination of the mechanical equivalent of the mean heat unit. The specific heat of water should also be determined at higher temperatures for the better determination of the heat of the liquid.

We believe that this work can best be done at the United States Bureau of Standards.

2 The pressure-temperature-volume relation of superheated steam should be determined experimentally at high pressures and over as wide a range of superheats as possible.

We believe that this work can best be done at the Massachusetts Institute of Technology under direction of Prof. Frederick G. Keyes.

3 The density of liquid water should be redetermined accurately over a wide temperature range above that at which satisfactory data are now available.

We believe that this work can best be done at the Massachusetts Institute of Technology under the direction of Prof. Frederick G. Keyes. We understand that in this connection Professor Keyes will be able to check the vapor-pressure curve of Holborn and Baumann.

4 The Joule-Thomson cooling effect in superheated steam should be determined at pressures up to 600 lb. and at temperatures up to 600 deg. fahr.

We believe that this work can best be done at the Harvard Engineering School under the direction of Prof. Harvey N. Davis.

5 Independent measurements of the specific heat at constant pressure of superheated steam should be made at higher pressures than those covered by the Munich experiments as a check on the volume and Joule-Thomson measurements. This work should be undertaken at the earliest possible moment. At present no one seems willing to undertake this work.

We believe that it could best be done at the United States Bureau of Standards, and that they should be requested to undertake it as soon as other conflicting work can be finished.

We estimate that this program could be undertaken at a cost of about $35,000 a year, and we hope that it could be completed in about three years.

We earnestly recommend that The American Society of Mechanical Engineers undertake the furtherance of this research program through its Research Committee, and that the Society undertake to receive and administer the necessary funds. We wish to recommend this program to the favorable consideration of the various interests concerned with the use of steam and to request their financial coöperation in making its realization possible.

John Fritz Medals Presented at International Gatherings

Representatives of Four National Engineering Societies Visit England and France—Sir Robert Hadfield and Eugene Schneider Recipients of John Fritz Medals—Engineering Institutions of England Confer Honorary Memberships on Visiting American Engineers

AMERICAN engineers have felt a great admiration and gratitude for the work performed by the engineers of England and France during the war and their activities in reconstruction since. The desire to convey these sentiments in a personal manner to those of the profession allied with them in the war, together with the inability of Sir Robert Hadfield, the recipient of the 1921 John Fritz Medal, to come to this country to receive the medal in person, led to the development of a plan to send a delegation of representative American engineers to England. The anticipation of the 1922 award to Eugene Schneider by the John Fritz Medal Board of Award broadened the plan so that similar ceremonies were carried out in France.

Organizers of the expedition, feeling that the scientific and technical coöperation built up during the war was a very solid foundation on which to build wider sympathies and better understandings between these three countries, therefore included the presentation of the John Fritz Medals for 1921 and 1922 as a feature of international ceremonies of marked importance in the beginning of an era of closer association of the ideals and activities of the engineers of the United States, Great Britain, and France.

Robert A Cummings Charles T. Main Jesse Merrick Smith F B Jewett William Kelly
Ira N Hollis Arthur S Dwight Ambrose Swasey Charles F Rand John R Freeman

The deputation consisted of twelve distinguished engineers representing the four national engineering societies of America. Their names and the societies they represented are as follows:

John Fritz Medal Board of Award:
AMBROSE SWASEY, *Chairman*

American Society of Civil Engineers:
CHARLES T. MAIN
ROBERT A. CUMMINGS
JOHN R. FREEMAN.

American Institute of Mining and Metallurgical Engineers:
COL. ARTHUR S. DWIGHT
CHARLES F. RAND, Secretary John Fritz Medal Board of Award
WILLIAM KELLY.

The American Society of Mechanical Engineers:
DR. IRA N. HOLLIS
JESSE M. SMITH.

American Institute of Electrical Engineers:
DR. F. B. JEWETT
DR. A. E. KENNELLY
MAJOR-GENERAL G. O. SQUIER.

The John Fritz Medal Fund was established in 1902 by friends and associates of John Fritz as a means of perpetuating the memory of his achievements in industrial progress, and the medal itself is one of the highest honors conferred by American engineers. It is awarded annually for scientific and industrial achievement in any field of pure or applied science, the first award being made in 1902 to John Fritz, and the second in 1905 to Lord Kelvin. Others among those who have since received the medal are George Westinghouse, Dr. Alexander Graham Bell, Thomas A. Edison, Sir William H. White, Robert W. Hunt, Elihu Thomson, Dr. James Douglas, Prof. H. M. Howe, Gen. Geo. W. Goethals, and Orville Wright. The Board of Award is made up of representatives of the four national engineering societies, one member of each society being elected annually to serve for a period of four years. The present board consists of the following men:

A.S.C.E.	Geo. H. Pegram F. S. Curtis Arthur N. Talbot Arthur P. Davis	A.I.M.E.	Herbert Hoover C. R. Corning Charles F. Rand Benj. B. Thayer
A.S.M.E.	Ambrose Swasey Henry B. Sargent F. J. Miller W. M. McFarland	A.I.E.E.	E. Wilbur Rice Calvert Townley Comfort A. Adams A. W. Berresford

Sir Robert Hadfield, the recipient of the 1921 medal, has taken a prominent part in the development of the steel industry. In addition to the invention of manganese steel, for participation in which he was awarded the medal, he has invented a magnetic steel of high permeability and other valuable steel alloys. During the war he was one of the largest producers of munitions for the British Navy. As a member of various scientific societies of Great Britain he has contributed largely to their growth; he is also an honorary member of the American Institute of Mining and Metallurgical Engineers. He is a pioneer in advocating in Great Britain the getting together of the engineering societies of the kingdom just as they have done in the United States, with common headquarters, a joint library, etc.

Eugene Schneider was awarded the 1922 medal for "achievement in metallurgy of iron and steel; for development of ordnance, especially the 75-mm. gun, and for notable patriotic contribution to the winning of the war." He has been head of the Creusot engineering and steel works of France since the death in 1898 of his father, who in his lifetime was an Hon. Mem. Am.Soc.M.E., and has given a great deal of attention to the well-being of his employees, as well as leading in the development of the steel and engineering industries of France. He is a member of various French clubs and societies and has been the recipient of many honors at home and abroad. M. Schneider is the first engineer outside the English-speaking world to receive the medal.

The presentation of the medal to Sir Robert took place at the opening conference of the British Institution of Civil Engineers in London on June 29. The meeting was attended by many eminent British engineers and scientists and also by the American ambassador and Viscount Bryce, representing Mr. Lloyd George. The president, Mr. J. A. Brodie, welcomed the deputation to the institution and to the country. Dr. Ira N. Hollis, representing the four American national engineering societies, delivered an address in which he conveyed the best wishes of the engineers of the

United States to those of Great Britain and expressed the hope that eventually engineers not only in the United States but in Canada, Great Britain and South Africa—all speakers of the same language—would be banded together for the welfare of the world. He spoke at some length on the admiration of engineers of this country for the achievements of British engineers during the war and the advantages to be gained by close coöperation between engineers of the two nations. He outlined the problems of the day in which engineers should take a leading part and closed by presenting an engrossed message to the engineers of Great Britain from the members of the four American national engineering societies in which these sentiments of admiration and good will were set forth.

Following the address by Dr. Hollis, Col. Arthur S. Dwight, representing the American Engineering Council of The Federated American Engineering Societies, as well as the American Institute of Mining and Metallurgical Engineers, presented the greetings of American engineers in the form of a resolution adopted by the Council expressing appreciation of the achievements of British engineers during the war and sympathy for the sacrifices involved, and a desire for close coöperation and mutual interest among the members of the engineering profession in England and the United States in the problems of reconstruction.

Dr. W. C. Unwin, who was asked to reply on behalf of the British engineers, spoke in appreciation of the assistance rendered by the United States in the war and of the engineering work in which engineers of the two countries are working together. He felt that the attendance of the delegation to the Conference was an indication of the better human relations spreading through the United States and Britain.

Lord Bryce, on behalf of those present who were not engineers, welcomed the delegation and shared the sentiments expressed by Dr. Hollis. He emphasized the international character of the engineering profession and congratulated members of the profession on their opportunities.

Ambrose Swasey, as chairman of the John Fritz Medal Board of Award, then presented the medal for 1921 to Sir Robert Hadfield, sketching briefly the history of the medal and the attainments of Sir Robert for which it was presented to him.

Sir Robert, in accepting the award, said that he regarded it not only as an honor conveyed upon him but as an expression to the British nation, on the part of the engineers of the United States, of their high regard and appreciation of the work of the British engineer in the war.

In connection with the award made to him Sir Robert submitted an address covering the history of the John Fritz Medal, the work of the United Engineering Societies in the United States, references to manganese steel and its applications, a general statement concerning his own research work, with a final section dealing with the history and work of the Royal Society. He has also presented a set of engineering papers and presidential and other addresses to the Engineering Societies Library, New York, to be permanently available for inspection and reference.

Other events participated in by the American delegation during its visit in England include a dinner party on the evening of June 27 given by Mr. Swasey, also one on June 28, at which the president and council of the British Institution of Civil Engineers were hosts; and an inspection of the National Physical Laboratory on June 28. On June 30 the deputation attended general meetings in the auditorium of the Institution of Mechanical Engineers, and in the evening were dinner guests of the president and council of the Institution of Electrical Engineers.

On July 8 the deputation went to Paris to present the 1922 medal to M. Schneider. The ceremonies followed the general plan of those in England. Greetings were extended to the engineers of France through La Société des Ingénieurs Civils de France in a resolution of the American Engineering Council similar to that presented to the British engineers.

The party was conducted through the Eiffel Tower by its builder, Alexandre Gustav Eiffel, who was afterward host at a luncheon which was served on the uppermost platform of the tower structure.

It is to be hoped in connection with these events bringing together engineers of Great Britain and the United States that a movement may be developed to bring into still closer coöperation the engineering societies of the British Empire according to the general plan of the American engineering societies.

During the visit of the American engineers to England and France leading engineering institutions of England conferred honorary membership upon four of the group and at a special session of the French Society of Civil Engineers, Ambrose Swasey was made an officer of the Legion of Honor and an honorary member of the Société. He also became an honorary member of the British Institution of Mechanical Engineers, the British Institution of Mining Engineers, the British Institution of Mining and Metallurgy and the Athenæum Club. The two mining institutions, the Athenæum Club, and the Iron and Steel Institute of Great Britain, conferred honorary membership upon Charles F. Rand, and the Institution of Mining Engineers honored Col. Arthur S. Dwight and William Kelly in a similar manner.

Ambrose Swasey is well known in the mechanical world and scientific circles on both sides of the Atlantic. His first inventions were the epicycloidal milling machine and a new process for generating and cutting spur gears. The Warner and Swasey Company, formed in 1880 for the manufacture of machine tools, was soon engaged also in the design and manufacture of astronomical instruments, and has been largely responsible for the development of the world's largest telescopes from the time of the 36-in. Lick refractor constructed in 1886 to the 72-in. reflecting telescope completed in 1916 for the Dominion Astronomical Observatory at Victoria, Canada.

Dr. Swasey has taken a large part in the design of these telescopes and of many other astronomical instruments, including an extremely accurate dividing engine for graduating astronomical circles. He has also developed instruments for seacoast defense and the Swasey range finder.

Dr. Swasey's efforts have ever been toward the advancement of the engineering profession and education in general, and among his many gifts for this purpose are the observatory at Denison University; the science building at the University of Nanking, China; the Y. M. C. A. building at Nanking; and $500,000 for the establishment of the Engineering Foundation.

The honorary degree of doctor of engineering was conferred upon him in 1905 by the Case School of Applied Science, and that of Sc.D. by Denison University five years later. He became a chevalier in the Legion of Honor in 1900.

Dr. Swasey has been a member of the A.S.M.E. since its organization in 1880 and was its president in 1904. He was made an honorary member in 1916. He is a member and past-president of the Cleveland Engineering Society, a member of the Institution of Mechanical Engineers of Great Britain and the British Astronomical Association, and a fellow of the Royal Astronomical Society. He was recently made an honorary member of the American Society of Civil Engineers.

Charles F. Rand, a leading figure in industrial research and a prominent mining engineer of New York City, is director and a past-president of the American Institute of Mining and Metallurgical Engineers and secretary of the John Fritz Medal Board of Award. Mr. Rand is also a member of the American Iron and Steel Institute, the National Research Council, and the American Society for Testing Materials. He is a past-president of the United Engineering Societies and chairman of the Executive Board of Engineering Foundation.

Mr. Rand is identified with the construction of railways and the opening and operation of iron mines in Cuba, and with the iron ore mining industry in the Lake Superior District, besides being largely interested in mines of manganese and copper ores.

In 1913 Mr. Rand was decorated by King Alfonso of Spain with the Grand Cross of Knight Commander (Comendador con Placa) of the Order of Isabella Catolica, for distinguished services to Spain and to mining. He now becomes one of five honorary members of the Iron and Steel Institute, the others being the Prince of Wales, King Albert of Belgium, and Dr. Richard Akerman and Baron Gustaf Tamm of Stockholm.

Col. Arthur S. Dwight, consulting mining and metallurgical engineer of New York, is vice-president of the American Institute of Mining and Metallurgical Engineers and a member of the American Electrochemical Society and the Institution of Mining and

Metallurgy (London). He is a former trustee of Columbia University and one of its leading alumni; he is actively interested in the development of the university's engineering school.

Colonel Dwight has engaged in mining and smelting in the United States and Mexico and is a patentee of the Dwight and Lloyd system of blast roasting of fine ores. He served continuously in France throughout the war, receiving the D.S.O. and other recognition for service.

William Kelly is a member and former director of the American Institute of Mining and Metallurgical Engineers. He is also a member of the Mining and Metallurgical Society of America, the Lake Superior Mining Institute (of which he was president in 1899), and the Institution of Mining and Metallurgy (London), and a fellow of the American Association for the Advancement of Science.

Mr. Kelly has had wide experience as chemist, manager and superintendent in various mining undertakings in Pennsylvania, Ohio and Michigan. He was president of the Board of Examining Engineers for Bituminous Mines Inspectors for Pennsylvania from 1885 to 1889. He has also acted as a member and as chairman both of the Public Domains Commission of Michigan and of the Board of Michigan College of Mines.

NEWS OF OTHER SOCIETIES

American Institute of Electrical Engineers

Annual convention at Salt Lake City, Utah, on June 21 to 24. Water power and long-distance transmission of electric power were the subjects of the principal papers. John L. Harper and J. A. Johnson of the Niagara Falls Power Co. surveyed the progress in the development of water power at Niagara Falls. A continuous flow of 200,000 cu. ft. per sec. passes through the Niagara River. Of the total fall of 336 ft. between Lakes Erie and Ontario, there is a head of 314 ft. that may be developed within about five miles. By an international treaty entered into in 1906 between the governments of the United States and Canada it has been agreed not to divert for power purposes more than 20,000 cu. ft. per sec. on the American side and 36,000 cu. ft. per sec. on the Canadian side. The entire amount of 20,000 cu. ft. per sec., which is available in the United States under the existing treaty, has been utilized, but with varying efficiency. One of the early plants obtains 12.1 hp. per cu. ft. per sec., while in Station No. 3 Extension, completed in 1920, 21 hp. per cu. ft. per sec. is developed. The total power generated in the five plants on the American side is 385,000 hp. If the five plants would operate at the efficiency of Station No. 3 Extension their combined power would be 420,000 hp. Thus, a loss of 34,500 hp. is traceable to inefficient utilization.

W. M. White, of the Allis-Chalmers Co., spoke on Advances in the Art of Water-Wheel Designs and Settings. The present tendency in hydroelectric practice, he said, is to develop each power site completely and to use larger units that will permit the maximum utilization of water power available. The working speed of units is increasing steadily. The best material for runners, according to Mr. White, is bronze without any zinc.

Long-Distance Transmission of Electric Energy was discussed by L. E. Imlay of the Superpower Survey, New York, N. Y. This paper was based on studies made in connection with the development of a superpower system for the industrial district along the Atlantic seaboard. In Voltage Regulation and Insulation for Large Power, Long-Distance Transmission Systems, Frank G. Baum, consulting engineer, San Francisco, Cal., proposed 220,000 volts as standard for national transmission systems. Two other papers on long-distance transmission of power were presented: Some Transmission Line Tests, by W. W. Lewis; and Notes on the Operation of Large Interconnected Systems, by L. L. Elden.

Numerous committee reports were submitted. The committee on the iron and steel industry reported progress in the simplification of control equipment for reversing-mill and finishing-mill drives. The committee on power stations pointed out developments in the design of large power stations such as the Colfax Power Station in Pittsburgh, the Hell Gate Station in New York City, the Delaware Station in Philadelphia and the Calumet Station in Chicago. Increased activities in research work in the colleges were reported by the committee on technical education.

American Society for Testing Materials

Annual meeting at Asbury Park, N. J., on June 20–24. More than 150 specifications were discussed. Of these, 71 were presented for the first time, 63 were revised, and others finally adopted as standard. Steel standards were changed to permit acceptance of steel made by duplex or more complicated processes. The provision adopted as a war emergency permitting the increase by one per cent of the sulphur and phosphorus limits on a considerable number of steel standards was removed from ten of the fourteen specifications on which it still remained. The society, however, is conducting in coöperation with other technical organizations numerous experiments to determine the effect of residual sulphur and phosphorus in otherwise normal open-hearth rolled steel products. The results thus far obtained led to the decision that it would involve no danger to extend permanently the sulphur limits from 0.05 to 0.06 per cent on structural steel for locomotives, cars and ships, owing to the heavy tonnages involved and to the continued difficulty in obtaining low-sulphur fuels and melting stock.

The phosphorus and sulphur limits were both extended 0.01 per cent for steel castings for the same reason. The sulphur limit is thus now reduced on all materials that are to be worked hot and increased on structural materials that are to be fabricated cold.

The committee on corrosion of iron and steel reported that the results of exposing uncoated sheets to atmospheric action indicated that copper-bearing metal is markedly superior in rust-resisting properties to non-copper-bearing metal of the same composition.

A preliminary specification for concrete was submitted by a joint committee composed of 25 members, five each from the American Society of Civil Engineers, the American Railway Engineering Association, the American Concrete Institute, the Portland Cement Association and the American Society for Testing Materials. The specification takes up the subject under the headings: materials, proportioning and mixing concrete, depositing concrete, forms, details of construction, waterproofing and protective treatment, surface finish, and design.

Facts regarding the testing and proportioning of concrete brought out through numerous tests conducted in various laboratories were presented by the committee on concrete and concrete aggregates. The cylindrical shape has been found to be the best for concrete specimens. A specimen having a height twice the diameter is recommended. Specimens of concrete stored in dry air from the time of mixing were found to gain but slightly in strength from 28 days up to a period of several months or even years.

R. S. MacPherran recorded tests made in the laboratory of the Allis-Chalmers Manufacturing Co. to determine the comparative properties of various alloy steels at high temperatures. The work was undertaken with a view to obtaining information as to the best material for use under operating conditions of 600 to 1000 deg. fahr. No temperature was found at which all steels showed a decided change in physical properties. The maximum tensile strength for rolled carbon steel, annealed, and forged 3.25 per cent nickel steel, annealed, occurred at between 600 and 650 deg. fahr. The maximum tensile strength usually occurred at a higher temperature than the minimum ductility. Other technical papers were: Impact Tests on Cast Steel, by F. C. Langenberg; Magnetic Spring Testing, by T. Spooner and I. F. Kinnard; A Test for Shock Strength of Hardened Steel, by C. E. Margerum; Improvements in Apparatus for Testing Petroleum Products, by T. G. Delbridge; and Some Mechanical Properties of Hot-Rolled Monel Metal, by P. D. Merica.

American Society of Heating and Ventilating Engineers

Semi-annual meeting in Cleveland on June 14 to 17. An experimental study on the resistance of materials to the flow of air was presented by A. E. Stacey, Jr. The following conclusions were formulated: (1) That the resistance of air filters varies directly with the velocity of the air through the material; (2) that the resistance is not affected by variations in relative humidity; (3) that the resistance of cotton felt is approximately 100 per cent greater than wool felt of the same weight.

A paper on By-Product Coke Ovens and Their Relation to Our Fuel Supply was read by E. B. Elliott. After reviewing the decreasing reserves of coal, petroleum, natural gas and wood and the

possibilities of conserving these fuels, Mr. Elliott pointed out the unlimited capabilities of the coking process in by-product recovery. He detailed the construction and operation of coke ovens, coke preparation and yields from a ton of coal, and studied the utilization of coke as domestic fuel. The society went on record as favoring a greater production of coke and its increasing use for domestic purposes.

Information on the application of gas to heating residences and commercial buildings was given by Thomson King. A survey of developments in the design of centrifugal fans, together with a description of a new type of multi-blade fan with double-curved blades, was presented by F. W. Bailey and A. A. Criqui (see p. 542 ante).

American Boiler Manufacturers' Association

Annual convention at Bedford Springs, Pa., on June 20 to 22. Progress was reported on the work being undertaken jointly by the Association and the Uniform Boiler Law Society in preserving unity among the states that have already adopted boiler legislation and in urging others to do so.

E. R. Fish reported as the representative of the association on the Boiler Code Committee of The American Society of Mechanical Engineers. A subcommittee was appointed by the Boiler Code Committee to consider the question of Rules for Inspection. Differences of opinion arose particularly in regard to the tolerances that an inspector may make in enforcing the Code. The apprehensions of boiler manufacturers were aroused in consequence of a questionnaire sent out to them soliciting their views. In order to assure the Association that nothing was to be done without their knowledge and coöperation, the Boiler Code Committee asked the Association to suggest some of its members to be added to the Sub-committee, and Starr H. Barnum, R. G. Cox, and Lawrence Connelly were named for that purpose. The report of the subcommittee will have to be discussed at a public hearing before it can be made a part of the Code.

F. R. Low, editor of *Power*, spoke on the Duties and Possibilities of a National Board of Boiler Inspectors. H. L. Parks, of Arthur G. McKee & Co., Cleveland, read a paper on the Proper Method of Filing and Numbering Drawings.

LIMITATIONS OF STOKERS USING MID-WEST COALS

(Continued from page 537)

high capacity. This is on account of the necessity, even with the so-called clinker grinder, of getting the clinker loosened up and into the ashpit by the use of bars in the side doors of the furnace. The ironwork at the rear of the stoker, under conditions just mentioned, comes in for very severe service, and the repairs thereto are likely to be excessive.

Some types of overfeed stokers have been used with good success in this section; and where only a limited capacity is required and suitable coal is available, results that will compare favorably with those from other stokers can be obtained.

The necessity of securing improved refractories, as well as improving the furnace design, is emphasized by the difficulties encountered with the brickwork when high boiler capacities are obtained. While this condition is probably in no way peculiar to stokers using coal from this section, it is possible that it may prove to be one of the factors governing the capacity which will be obtained in future installations.

One condition of primary importance to the stoker manufacturer has come about in the past few years, and that is that the class of help in the boiler room has improved to such an extent that a piece of equipment is not barred from consideration on the ground that it requires intelligence to operate it.

Engineering and Industrial Standardization

Elevator Standardization

The Plan and Scope Committee of the Sectional Committee on the Standardization of Elevators has completed its work and submitted its report to the Sectional Committee. The following are a few extracts from the report which it is believed will be of general interest.

The value of standardization as applied to elevators has been unanimously attested to by the representatives of all the organizations from which the members of the Sectional Committee have been selected. (See March 1921 issue of Mechanical Engineering, p. 218.) In fact, there has been a natural process of standardization as to type throughout the evolution of the modern elevator.

While it is generally recognized that the elevator has been perhaps the most important factor in the development of high buildings, very few appreciate the fact that in large centers of population in this country more passengers are carried by vertical means of transportation than by horizontal means. To give an idea of the extent of elevator traffic, it may be stated that in the Borough of Manhattan there are approximately 23,000 elevators, of which about 12,000 are passenger elevators. From data collected it has been calculated that the latter carry over 12,000,000 persons per day, which is approximately twice the number of passengers carried by the railroads and other horizontal transit facilities of Manhattan Island.

Considering the importance of vertical transportation, it is manifestly well worth while to make an earnest effort to improve the instrumentality for such service—the modern elevator. Some of the specific benefits of this standardization are as follows:

a It will give increased safety and better service to elevator users, the passengers

b It will make it possible for the owner to select an installation suitable for his purpose

c It will reduce first cost, as well as the time required to complete the elevator installation

d It will reduce the cost of maintenance and facilitate securing spare parts.

These values cannot be realized, however, unless the standards are accepted and intelligently used by producers and consumers. Hence it seems advisable that means should be provided immediately for informing both producers and consumers concerning the work which is being done, and ultimately as to the use of the proposed standards. Full publicity following careful standardization will not only tend to bring the manufacturer to a realization of the faults or incompleteness of his apparatus, but it will educate the consumer so that there will be less insistence than at present on the installation of inefficient or inadequate apparatus. To accomplish this end it is proposed to give the subject publicity in the technical press and in the publications of the organizations represented in the Sectional Committee.

The work of the Committee comprises the setting up of standards for both passenger and freight services, and their application not only to the elevator mechanism but also to the hoistway structure as an integral part of the means for vertical transportation. The result of the work should be the following:

Standards. The presentation in suitable form of—

- *a* Fundamental principles governing elevator service
- *b* Technical information sufficient for at least a general determination of elevator plants
- *c* Technical information sufficient for the formulation of specifications covering elevator plants.

Standardization of Design. The presentation in suitable form of—

- *a* Description in general of the design of the several types of hoistway structure and elevator mechanism conforming to the standards promulgated
- *b* Description in detail of the design of such parts of hoistway structure and elevator mechanism as are necessary to make them "fit" together
- *c* Description in detail of the design of such parts of both the hoistway structure and the elevator mechanism as

it may be practicable to standardize dimensionally.

In setting up the standards and in the standardization of design all of the following elements should be considered in the sequence of importance as given: (1) Safety; (2) Maintenance of Operation; (3) Quality of Service; (4) Quantity of Service; (5) Cost of Maintenance; (6) Initial Cost of Elevator Installation; (7) Depreciation and Amortization.

The Report proposes the organization of the following sub-committees to carry on this work:

1 A committee on engineering standards for passenger traffic
2 A committee on engineering standards for freight traffic
3 A committee whose problem will be the standardization of hoistway construction
4 A committee whose problem will be the standardization of elevator construction
5 A consulting committee to pass on the work of the other committees.

Copies of the complete Report may be obtained on application to the A.S.M.E. Standards Department.

A.I.E.E. Standards Submitted for Approval

The American Institute of Electrical Engineers has submitted its Standards (1921 edition) to the American Engineering Standards Committee for approval as an American Standard. This is done in accordance with the special provision in the procedure of the Committee under which important standards adopted or in process prior to 1920 may be approved without passing through the regular procedure. The standards submitted represent the latest revision of the A.I.E.E. standardization rules, revised during 1919 and 1920. These rules were first issued in 1899, so that they may be considered in truth a standard which has by actual practice proved its right to become an American Standard.

The American Engineering Standards Committee would be very glad to learn from those interested of the extent to which they make use of these specifications and to receive any other information regarding the manner in which the specifications are meeting the needs of the industry.

Standards Recently Approved by the A.E.S.C.

Standards recently approved by the American Engineering Standards Committee include four copper specifications submitted by the American Society for Testing Materials as Tentative American Standards, as follows:

Soft or Annealed Copper Wire
Lake Copper Wire, Bars, Cakes, Slabs, Billets, Ingots, and Ingot Bars
Electrolytic Copper Wire Bars, Cakes, Slabs, Billets, Ingots, and Ingot Bars
Battery Assay of Copper.

Sectional Committees Recently Designated by the A.E.S.C.

In compliance with the request of the American Institute of Electrical Engineers, the American Engineering Standards Committee has designated the A.I.E.E. sponsor for the formation of a sectional committee on Standard of Aluminum for Conducting Purposes.

In conformity with the request of a conference of interested national organizations, the American Engineering Standards Committee has designated the American Institute of Architects, the American Institute of Electrical Engineers, and the National Association of Electrical Contractors and Dealers joint sponsors for a sectional committee on Symbols for Electrical Equipment of Buildings and Ships.

Upon recommendation of its General Correlating Committee for Mining Standardization, the American Engineering Standards Committee has authorized the organization of sectional committees on Safety Rules for Installing and Using Electric Equipment in Bituminous Coal Mines· Portable Electric Mine Lamps; and Storage-Battery Locomotives for Use in Gaseous Mines. The U. S. Bureau of Mines has been designated as sponsor for each of these sectional committees.

Boiler Code Committee Meets in Rochester

The June meeting of the Boiler Code Committee of the A.S.M.E. was held in Rochester, N. Y., where the Committee members were the guests of S. W. Miller, member of the Sub-Committee on Welding, F. A. Collins, Jr., Secretary of the Rochester Local Section of the Society, Roger DeWolf of the Rochester Railway Light Company, A. I. Jones and W. B. Miller of the Pfaudler Company. Through the courtesy of the Pfaudler Company, the library of their office in the Cutler Building was utilized for the Committee meetings which were held in two sessions, June 23 and 24, and the hotel headquarters of the meeting was at the Hotel Seneca.

The purpose of the meeting was to consider a report of the Sub-Committee on Miniature Boilers and a number of communications which were acted upon as formal interpretations. This report however, was tentative and the Sub-Committee received instructions from the Committee for the continuation of its work. In addition to the above proceedings, on June 23 hearings were granted to inquirers who came personally before the Boiler Code Committee.

The second day of the meeting, June 24, was devoted to revision work and excursions to a number of mechanical plants in Rochester.

TECHNICAL PROBLEMS IN AERONAUTICS

(Continued from page 528)

Captain Stevens also explained the need for oblique and vertical pictures which, viewed through the proper apparatus, cause the ground detail to stand out in relief. The two aerial photographs shown on page 528 illustrate oblique views at different heights.

Machine-Gun Synchronizers

In his remarks on machine-gun synchronizers H. O. Russell emphasized the need of a synchronizing gear to control machine-gun fire to prevent bullets from striking the propeller blades, especially with the high-powered engines of today where one shot through the propeller may splinter it sufficiently to unbalance the engine, thus causing it to tear itself loose from the bed.

The synchronizing gear is essentially a mechanism connecting the engine and the trigger of the machine gun. The machine-gun fire is interrupted when the blade of the propeller is opposite the bore of the gun. The original patent taken out by the Germans in 1913 consisted of a tappet rod operating from a cam on the engine and extending to the rifle trigger. The French overcame the difficulties of wear, whip and chatter of this mechanism by utilizing an oscillating rod. The English developed the C. C. Hydraulic Gear which maintained communication between the engine and trigger by means of compressional waves in oil. Leaks and air pockets affect the proper functioning of this gear.

In the Nelson gun control the impulse from the engine is transmitted to the machine gun by a pull on a wire. This scheme has operated satisfactorily, but the wire cable must be led from the engine to the machine gun in a straight path, which limits the variety of installations possible.

Three systems have been designed and have been tested out to eliminate the defects of the Nelson gun control. One utilizes a flexible brass tube carrying the impulse cable from the engine to the machine-gun trigger through a flexible shaft. This requires a large shaft so that it will come up to speed within one-half revolution and stop within one-half revolution. Considerable work has been done upon electrical mechanisms, and although a satisfactory one has been developed, it is quite heavy and complicated. Some further advances are contemplated on the electric gear.

A Correction

In the discussion on the paper by W. M. White on the Hydraucone Regainer published in the July issue of Mechanical Engineering, the remarks made by M. Spillman, chief engineer of the Worthington Pump and Machinery Corporation, Harrison, N. J., were in error, credited to C. B. Spellman of Philadelphia, Pa.

THE ENGINEERING INDEX

(Registered U. S. Patent Office.)

THE ENGINEERING INDEX presents each month, in conveniently classified form, items descriptive of the articles appearing in the current issues of the world's engineering and scientific press of particular interest to mechanical engineers. At the end of the year the monthly installments are combined along with items dealing with civil, electrical, mining and other branches of engineering, and published in book form, this annual volume having regularly appeared since 1906. In the preparation of the Index by the engineering staff of The American Society of Mechanical Engineers some 1200 technical publications received by the Engineering Societies Library (New York) are regularly reviewed, thus bringing the great resources of that library to the entire engineering profession.

Photostatic copies (white printing on a black background) of any of the articles listed in the Index may be obtained at a price of 25 cents per page, plus postage. A separate print is required for each page of the larger periodicals, but wherever possible two small or medium-sized pages will be photographed together on the same print. The bill will be mailed with the print. When ordering photostats identify the article by quoting from the Index item: (1) Title of article; (2) Name of periodical in which it appeared; (3) Volume, number, and date of publication of periodical; (4) Page numbers. Orders should be sent to the Engineering Societies Library, 29 West 39th Street, New York.

ACCIDENT PREVENTION

Steel Erection. Instructions to Foreman for Prevention of Accidents in Steel Erection. Eng. & Contracting, vol. 55, no. 21, May 25, 1921, pp. 518–521. Prepared by erection department of McClintic-Marsball Co., Pittsburgh, Pa.

AERODYNAMICS

Motion in a Resisting Medium. Motion of the Center of Gravity of a Symmetrical Solid with Relation to a Vertical Plane Moving in a Resisting Medium (Mouvement du centre de gravité d'un solid symétrique par sapport à un plan vertical se déplaçant dans un milieu résistant), M. Alayrac. Comptes rendus des Séances de l'Académie des Sciences, vol. 172, no. 18, May 2, 1921, pp. 1089–1092, 1 fig. Study of mechanical problem involved and its application to aeroplane in flight.

AERONAUTICAL INSTRUMENTS

Anschutz Horizon. German Gyro Gauges, Alfred Gradenwitz. Aeronautics, vol. 20, no. 398, June 2, 1921, pp. 390–391, 5 figs. Anschutz gyrocompass for determining angle of inclination of aeroplane in regard to horizon.

Speed Indicators. The Altitude Effect on Air Speed Indicators, Mayo D. Hersey, Franklin L. Hunt and Herbert N. Eaton. Nat. Advisory Committee for Aeronautics, report no. 110, 1921, 27 pp., 8 figs. Theoretical study of experiments with venturi tubes.

AEROPLANE ENGINES

Fuels. Fuels Used in Aeroplane Engines (L'essence et les combustible employés en aviation), M. P. Dumanois. Aérophile, vol. 29, nos. 7–8, April 1–15, 1921, pp. 110–114. Utilization of other fuels than gasoline in aeroplane engines. Tests conducted by French Aeronautical Technical Service.

Liberty. Induction System Pressures in Liberty Twelve and 300 H.P. Hispano-Suiza Aeronautical Engines, U. S. War Dept., Air Service Information Circular, vol. 3, no. 223, May 1, 1921, 12 pp., 7 figs. Determination of manifold, carburetor choke and float chamber depressions in standard Liberty twelve and 300-hp. Hispano-Suiza engines.

Performance Test of G.A.X. with Two 400 H.P. Liberty "12" Engines. U. S. War Dept., Air Service Information Circular, vol. 2, no. 193, Mar. 25, 1921, 8 pp., 5 figs. Endurance, full throttle at 10,000 ft. including climb was 1 hr. 48 min.; minimum speed at sea level, lowest throttle, 63.6 m.p.h.

Packard. The Packard "Altitude" Aero Engine, J. G. Vincent. Flight, vol. 13, no. 22, June 2, 1921, pp. 371–373, 7 figs. Engine designed for use at high altitudes. Standard compression ratio is 6½ to 1, but pistons giving 5½ to 1 ratio can be fitted for low-altitude work.

Performance. Experimental Study of Performance of Aeroplane Engines in Rarified Atmosphere (Étude expérimentale du fonctionnement des moteurs en atmosphère raréfiée), Mortinot-Lagarde. Aéronautique, no. 23, April 1921, pp. 175–177, 1 fig. Experiments with Lorraine-Dietrich engine.

Radiators. Turbulence in the Air Tubes of Radiators for Aircraft Engines, S. R. Parons. Nat. Advisory Committee for Aeronautics, report no. 106, 1921, 13 pp., 12 figs. Investigation of characteristics of flow in air passages of aircraft radiators.

Superchargers. Aeroplane Superchargers, W. G. Noack. Aerial Age, vol. 13, nos. 12, 13 and 15, May 30, and June 13 and 20, 1921, pp. 272–275, 5 figs.; 322–325, 23 figs. and 347–349, 18 figs. Technical study. Design of superchargers and effect of supercharging aeroplane engines. Swiss and German types. Translated from Zeitschrift des Vereines deutscher Ingenieure.

AEROPLANE PROPELLERS

Super-Speed. Super-Speed Propellers. Sci. Am., vol. 124, no. 22, May 28, 1921, p. 430, 3 figs. Air propellers with blade-tip velocity above that of sound.

AEROPLANES

Aerofoils. Report of Wind-Tunnel Test of U.S.A. 27 A, B, and C Airfoils. U. S. War Dept., Air Service Information Circular, vol. 3, no. 224, May 10, 1921, 12 pp., 10 figs. Tables giving lift, drag, lift-drag ratio and other characteristics of various types of aerofoils.

Wings. Ground-Plane Influence on Aeroplane Wings, A. F. Zahm and R. M. Bear. Aerial Age, vol. 13, no. 13, June 6, 1921, pp. 299–301, 5 figs. Technical study discloses material ground-plane influence at small incidence and ground gap. Life is augmented drag diminished; lift-drag may be increased 30 to 40 per cent.

PW-1. U.S.A. 27 Wings. U. S. War Dept., Air Service Information Circular, vol. 3, no. 225, May 5, 1921, 4 pp. Necessary changes to make in strut locations and sizes of members when span is reduced.

AIR COMPRESSORS

Piston. The Air Losses in Piston Compressors (Die Luftverluste bei Kolbenverdichtern), Arthur Balog. Fördertechnik u. Frachtverkehr, vol. 14, no. 9, Apr. 29, 1921, pp. 99–100, 2 figs. Equations for approximate determination of losses.

Lighthouses. Aerial Lighthouses (Le balisage lumineux), Edmond Marcotte. Aerophile, vol. 29, nos. 7–8, April 1–15, 1921, pp. 99–107, 6 figs. Notes on design of aerial lighthouses.

Soaring Flight. Experimental Studies of Soaring Flight (Études expérimentales sur le vol à voile), M. Idrac. Comptes rendus des Séances de l'Académie des Sciences, vol. 172, no. 19, May 9, 1921, pp. 1161–1164, 1 fig. Graphical record of vertical components of forces acting on flying kite.

Soaring—A New Theory of Flight. (Der Segelflug, eine neue Flugtheorie), Gustav Lilienthal. Annalen für Gewerbe u. Bauwesen, vol. 88, no. 8, Apr. 15, 1921, pp. 67–71, 10 figs. Investigation of the soaring flight of birds with regard to its application to aeroplanes; possibility of eventual flight without engine.

Speed of Flight. Obtaining Very High Speeds in Aviation by Using Constant Power Engines (Les très grandes vitesses en aviation par les moteurs à puissance constante), Auguste Forissier. Génie Civil, vol. 78, no. 15, April 9, 1921, pp. 138. Reference is made to note presented by M. Rateau before Academy of Sciences on June 23, 1919 where he discussed the maximum obtainable speed under present conditions. Present writer computes that it is now possible to fly with speed of 500 km. per hr.

Weather Reports. Daily Weather Report for Aviators by Radio. Aerial Age, vol. 13, no. 13, June 6, 1921, pp. 298–299. Explanation of bulletin issued by U. S. Weather Bur. in coöperation with Office of Communications of Navy Dept. Bulletin, which is intended for benefit of marine and aviation interest, began June 1, 1921.

B

BEAMS

Concrete. Design of Simple Reinforced Concrete Structural Members—II, Harold W. Barker. Concrete, vol. 18, no. 6, June 1921, pp. 285–287, 3 figs. Formulas for computing shear and bond stresses in beams.

BEARING METALS

Genelite. Self-Lubricating Bearings. Sci. Am., vol. 124, no. 24, June 11, 1921, p. 467, 3 figs. Bearing material, termed genelite, developed by Gen. Elec. Research Laboratory. Material is mixture of graphite and high-grade synthetic bronze.

BEARINGS

Anti-Friction. A New Patent Anti-Friction Bearing. Practical Engr., vol. 63, no. 1788, June 2, 1921, pp. 347–348, 5 figs. Roller bearing manufactured by Chain Roller Bearing Co., Stockport, England. Feature is employment of endless and detachable chain as separating and guiding means for rollers.

BEARINGS, BALL

Electric Cars. Destructive Effect of Current on Ball Bearings of Electric Cars, Hilding Angstrom. Elec. Ry. Jl., vol. 57, no. 21, May 21, 1921, pp. 941–944, 13 figs. Tests made under various conditions show that very rapid destruction of ball bearings results from electric current which flows through them. Types of construction are suggested for overcoming trouble and testing apparatus is described for reproducing conditions as they occur in service.

Railway Cars. Ball and Roller Bearings and their Use in Railroad Operation (Wälzlager und ihre Verwendung im Eisenbahnbetrieb), H. Heberling. Fördertechnik u. Frachtverkehr, vol. 14, no. 5, Mar. 4, 1921, pp. 58–60, 5 figs. Longitudinal and transverse bearings; advantages of ball and roller bearings over sliding bearings; their introduction into railroad practice; Swedish tests.

Standardization. International Ball Bearing Standardization, R. S. Burnett. Jl. Soc. Automotive Engrs., vol. 8, no. 6, June 1921, pp. 577–578. Proposed international standardization.

BENZENE

Still. A New Type of Benzene Still in European Operation, A. Thau. Chem. & Metallurgical Eng., vol. 24, no. 23, June 8, 1921, pp. 1013–1017, 11 figs. Tubular type Bamag benzene still. Still consists of number of horizontally arranged cylinder sections joined by flanged branches.

BENZOL

Recovery. A Benzol Factory of New Design at the Coking Plant of the Oxelösund Iron Works (Die Benzolfabrik neuer Bauart auf der Kokerei des Oxelösunder Eisenwerkes), A. Thau. Glückauf, vol. 57, nos. 1 and 2, Jan. 1 and 8, 1921, pp. 4–11 and 25–31, 13 figs. Factory constructed by the Berlin-Anhalt Machine-Construction Corp. (BAMAG in Sweden, in operation since beginning of 1920 including description of apparatus with which a continuous separation of the raw products in two fractions is effected. Table showing distillation of the raw products, etc., determined during period of measurements.

Recovery of Benzol from Gas (La récupération du benzol). Génie Civil, vol. 78, no. 20, May 14, 1921, pp. 409–414, 5 figs. Scheme for recovering benzol from city gas. Paper read before Société d'Encouragement pour l'Industrie nationale.

BLAST-FURNACE GAS

Cleaning. Notes on the Cleaning of Blast-Furnace Gas, S. H. Fowles. Iron & Steel Inst., annual meeting, May 5–6, 1921, advance paper no. 4, 21 pp. 7 figs. Calculations involved in design of Halberg-Beth dry-gas-cleaning plant. Comparison of Halberg-Beth plant with other plants.

BLAST FURNACES

Auxiliary Equipment. Machinery for Pig-Iron Beds at Blast Furnaces, F. W. Broy. Iron & Coal Trades Rev., vol. 102, no. 2777, May 20, 1921, pp. 689–690, 7 figs. Deals with pig breakers, crane for carrying breaking hammer and delivery magnets, and utilization of crane equipment. Translated from Zeit. des Vereines deutscher Ingenieure.

Cowper Stoves. Regulation of Pressure in Cowper Apparatus (Du regime des pressions dans les appareils Cowper), M. J. Seigle. Revue de Métallurgie, vol. 18, no. 3, Mar. 1921, pp. 140–146, 11 figs. Graphs for determining air pressure at various points of apparatus.

Hot-Blast Stoves. Design and Proportions of Hot Blast Stoves, W. E. Groume-Grjimailo. Iron Age, vol. 107, no. 23, June 9, 1921, pp. 1527–1530, 15 figs. Consideration of laws governing circulation of gases while heating and cooling. Historical designs reviewed.

Heat Distribution in Hot Blast Stoves, W. E. Groume-Grjimailo. Iron Age, vol. 107, no. 24, June 16, 1921, pp. 1613–1616, 3 figs. Hot-blast temperature equalizers. Analysis of performance results. Calculations of convection velocities.

Slags. Blast-Furnace and Cupola Slags, J. E. Fletcher. Iron & Steel Inst., annual meeting, May 5–6, 1921 advance paper no. 3, 20 pp., 12 figs. Their composition and graphic methods for determining their constitution.

BOILER FEEDWATER

Treatment. New Boiler Feed Water System. Blast Furnace & Steel Plant, vol. 9, no. 6, June 1921, pp. 392–394, 2 figs. We-Fu-Go system, which consists of two reaction-settling tanks holding 80,000 gal. each, equipped with mechanically operated stirring devices, driven by individual motors.

BOILER FURNACES

Improvements. Improvements in Furnace Installations for Solid Fuels (Neuerungen an Feuerungsanlagen für feste Brennstoffe), H. Pradel. Feuerungstechnik, vol. 9, no. 15, May 1, 1921, pp. 133–137, 10 figs. Details of recent German patents.

Phillips-Badenhausen-Stephens. Vertical Process of Combustion. Power, vol. 53, no. 22, May 31, 1921, pp. 875–876, 2 figs. Fuel is introduced at front of chamber, mixed with air and cast downward building up and thereafter maintaining incoherent, incandescent bed of fuel particles on furnace bottom. In downward movement dust and fine particles are burned before reaching bed.

BOILER OPERATION

Boiler Capacity. Burning More Coal to Increase Boiler Capacity, Thomas Wilson. Power, vol. 53, no. 23, June 7, 1921, pp. 924–927, 2 figs. Increasing boiler capacity by enlarging grate area, by adding to length or width of stoker, or by using forced-draft stokers. Practice of Commonwealth Edison Co.

Feeding. Boiler Feeding by Gravitation. Engr., vol. 131, no. 3410, May 6, 1921, pp. 491–492, 4 figs. Auto-thermal feeding system.

Stoker Firing. Changing a Hand-Fired to a Stoker-Fired Plant, Charles T. Main. Power, vol. 53, no. 24, June 14, 1921, pp. 954–957, 4 figs. Installation of twelve 3500-sq. ft. water tube boilers.

BOILER PLANTS

Oil-Burning. Automatic Oil-Burning Plant at Sugar Refinery, Claude C. Brown. Power Plant Eng., vol. 25, no. 12, June 15, 1921, pp. 599–602, 2 figs. Boiler plant consists of ten 600-hp. horizontal water-tube boilers.

Steel Mills. Cambria Steel Company New Boiler Plant, E. W. Trexler. Blast Furnace & Steel Plant, vol. 9, no. 6, June 1921, pp. 389–392, 4 figs. Plant consists of six 655-hp. water-tube boilers equipped with underfeed stokers, superheaters, soot blowers, automatic feed-water regulators, fuel economizers, draft regulators, forced-draft and induced-draft fans.

BOILERS

Bettington. Pulverized Fuel Boiler. Eng. Rev.,

vol. 34, no. 11, May 1921, pp. 288–289, 2 figs. Bettington boiler designed to burn pulverized coal.

Efficiency. Arrangements for Improvement of the Efficiency of Steam-Heating Boilers (Einrichtungen zur Verbesserung des Wirkungsgrades von Zentralheizungskesseln), Jos. Fichtl. Gesundheits-Ingenieur, vol. 44, no. 18, Apr. 30, 1921, pp. 201–208, 9 figs. Details of various German coke-saving devices, including firebrick furnace linings, bridge walls and other devices.

Electrically Operated. Electrically Heated Steam Boilers, Eric A. Lof. Gen. Elec. Rev., vol. 24, no. 6, June 1921, pp. 515–518, 3 figs. Comparison of relative heating values of fuel and electric heat. Installation of electrically operated boilers in Sweden.

Marine. See MARINE BOILERS.

BOILERS, WATER TUBE

Yarrow. The Water Drums of Yarrow Boilers. Engr., vol. 131, no. 3413, May 27, 1921, pp. 566–567, 6 figs. Types recently developed.

BOLTS

Industry. Development of the Bolt and Nut Industry. F. H. Chapin. Iron Age, vol. 107, no. 24, June 16, 1921, pp. 1609–1610. First machine-fabricated product made in this country only 80 yrs. ago.

BONUS SYSTEMS

Railway Work. Piece-Work, Bonus Systems and Higher Efficiency, C. C. Cook. Ry. Age, vol. 70, no. 22, June 3, 1921, pp. 1263–1264. Experience of Baltimore & Ohio Railroad.

BRAKES

Cranes, Tests. Testing Equipment for Pneumatic Motors, J. V. Hunter. Am. Mach., vol. 54, no. 21, May 26, 1921, pp. 894–896, 4 figs. Importance of performance records for portable air motors. Examples of testing equipment in several railroad shops.

Double-Capacity. Virginian Demonstration of Double-Capacity Brake. Ry. Age, vol. 70, no. 24, June 17, 1921, pp. 1407–1410, 8 figs. Brakes for 120-ton cars. Characteristic is that equipment provides for same percentage of braking force (ratio of total shoes pressure to car weight) on loaded car as on empty car.

Stresses. Piston Travel and Shoe Clearance, H. M. P. Murphy. Elec. Ry. Jl., vol. 57, no. 25, June 18, 1921, pp. 1119–1122, 10 figs. Study of forces developed in brake riggings. Determination of relation between piston travel and shoe travel.

BRASS

Cracks. Annular Cracks, R. R. Clarke. Metal Industry (N. Y.), vol. 19, no. 6, June 1921, pp. 243–244, 2 figs. Discussion of various theories accounting for their formation. (Concluded.)

Nickel. Brasses Containing Nickel, L. Guillet. Iron Age, vol. 107, no. 21, May 26, 1921, pp. 1380. Mechanical tests and microscopic examination of copper-nickel-zinc alloys. Translated from Revue de Métallurgie.

Scrap. The Use of Scrap of New Material in Rolled Brass Foundry Work, L. Kroll. Metal Industry (Lond.), vol. 18, no. 19, May 13, 1921, pp. 364–365. Laboratory experiments. Translated from Giesserei Zeitung.

Season Cracking. Season-Cracking of Brass, H. Moore, S. Beckinsale and Clarice E. Mallinson. Chem. & Metallurgical Engr., vol. 24, no. 22, June 1, 1921, pp. 976–980, 7 figs. Investigation at Woolwich Arsenal, England, on action of corrosive agents on stressed brasses and determination of minimum loads required to produce corrosion cracks. Chemical action was found to be necessary for season cracking. (Abstract.) Paper read before Inst. of Metals.

BUILDING CONSTRUCTION

Labor Hours. Labor Hours Per Output Unit in Building Construction, Frank E. Barnes. Eng. News-Rec., vol. 86, no. 21, May 26, 1921, pp. 888–891. Tables showing time required to accomplish unit of carpenter work, masonry, excavation, painting, plastering and sheet metal work.

BUILDING MATERIALS

Research. The Utility of Research on Building Materials, Alan E. Munby. Jl. Royal Inst. British Architects, vol. 28, no. 13, May 7, 1921, pp. 373–382, and (discussion) pp. 383–390, 13 figs. Progress achieved by Science Standing Committee of Royal British Architects.

BUILDINGS

Concrete, Surface Treatment. Treatment of Exterior Surfaces of Industrial Buildings. Concrete vol. 18, no. 6, June 1921, pp. 263–265. Classification of surface treatments and suggestions in regard to method to follow in a given case. Committee Report of Am. Concrete Inst.

C

CARBURETORS

Heavy-Fuel. The Carburation Phenomena of Heavy Fuels (Zur Kritik der Vergasungsvorgänge schwerer Brennstoffe), Carl Wirsum. Motorwagen, vol. 24, no. 13, May 10, 1921, pp. 257–259. Results of experiments.

CAR DUMPERS

Gravity. Rotary Car Dump that Operates Solely by Gravity. Coal Age, vol. 19, no. 24, June 16, 1921, pp. 1074–1076, 4 figs. Gravity, springs and flywheels discharge cars by revolving them through approximately 135 deg. Cars can be dumped in full trips, hence swivel couplings are not needed.

CAR WHEELS

Cast-Iron. Proposed Tentative Specifications for Cast-Iron Car Wheels. Am. Soc. for Testing Matls., paper of annual meeting, June 21–24, 1921, 4 pp.

CARS

Repair Shops. C. I. & L. Builds Modern Car Repair Shop. Ry. Age, vol. 70, no. 23, June 10, 1921, pp. 1325–1327, 4 figs. Steel-frame structure of longitudinal type 440 ft. long, 85 ft. wide and 40 ft. high.

Repairs. Scheduling Car Repairs Increases Shop Output, E. T. Spidy. Ry. Mech. Engr., vol. 95, no. 6, June 1921, pp. 349–352, 2 figs. Outline of schedule applicable to passenger or freight car repair work in large or small shops.

CARS, COAL

Hopper. A 70-Ton Hopper Car that can be Repaired in any Shop, H. Idoine. Ry. Rev., vol. 68, no. 24, June 11, 1921, pp. 894–899, 14 figs. Steel hopper car of 70-tons capacity built with interchangeable sheets and stakes.

100-Ton. Development of Coal Cars on the Norfolk & Western. Ry. & Locomotive Eng., vol. 34, no. 6, June 1921, pp. 160–163, 7 figs. Details of construction of 100-ton coal car.

New Norfolk & Western 100-Ton Coal Cars, John A. Pilcher. Ry. Mech. Engr., vol. 95, no. 6, June 1921, pp. 367–370, 10 figs. Tests to determine load on springs due to irregular track and clearance for curves.

Six-Wheel Trucks. New Designs of Buckeye Six-Wheel Trucks. Ry. Age, vol. 70, no. 22, June 3, 1921, pp. 1269–1270, 3 figs. Equalization of load is accomplished by use of equalizer casting which engages center journal.

CARS, PASSENGER

Design. On the Question of Passenger Carriages (Subject VII for discussion at the Ninth Congress of the International Railway Association), F. de Vargas. Bul. Int. Ry. Assn., vol. 3, no. 5, May 1921, pp. 461–506, 18 figs. Trend of developments in design of passenger cars by European and American railways since 1914.

Steel. The Steel Passenger Cars of the Prussian-Hessian State Railways—II, (Die eisernen Personenwagen der preussisch-hessischen Staatsbahnen), H. Speer. Zeit. des Vereines deutscher Ingenieure, vol. 65, nos. 20 and 21, May 14 and 21, 1921, pp. 511–516 and 549–552, 42 figs. Present practice in construction of steel passenger cars; basic principles underlying design; construction of express-train, mail and baggage cars, and slow-train cars; recommendations for new construction of latter; repair of steel passenger cars.

CENTRAL STATIONS

Developments. Central Stations Lead in Showing Spirit of Progress, Samuel Insull. Elec. Rev. (Chicago), vol. 78, no. 23, June 4, 1921, pp. 887–890, 1 fig. Developments and possibilities of interconnected power plants and superpower zones in U. S. Paper read before Nat. Elec. Light Assn.

Electric-Furnace Load. The Electric Melting Furnace as a Central Station Load, H. A. Winne. Gen. Elec. Rev., vol. 24, no. 6, June 1921, pp. 510–514, 6 figs. It is estimated from past growth in installation of electric steel furnaces that in 1925 power consumption by them will total 500,000,000 kw-hr.

France. Project for the Distribution of Electrical Energy in France by Means of High-Tension Electric Networks (Projet de répartition de l'énergie électrique en France au moyee des réseaux électriquee à haute tension), Ch. Lavanchy. Revue générale de l'Electricité, vol. 9, no. 21, May 21, 1921, pp. 727–733, 1 fig. Scheme for interconnection of hydroelectric and steam power plants. Energy to be transmitted at 150,000 volts.

Industrial Heating. Industrial Heating and the Central Station, E. H. Horstkotte. Gen. Elec. Rev., vol. 24, no. 6, June 1921, pp. 579–582, 8 figs. Survey of progress in utilization of electric heating in industry.

Load Equalization. Load Equalization, F. L. Stone and T. W. Kennedy. Gen. Elec. Rev., vol. 24, no. 6, June 1921, pp. 501–504, 6 figs. Study based on typical cases, notably power house supplying five mines.

Operation. Three Years Operation at Windsor, E. H. McFarland. Gen. Elec. Rev., vol. 24, no. 6, June 1921, pp. 572–578, 8 figs. Central station operated jointly by American Gas & Elec. Co. and West Penn Power Co.

Steel Mills. Steel Mill Power-Factor and the Central Station, A. K. Bushmand and A. L. Lemon. Gen. Elec. Rev., vol. 24, no. 6, June 1921, pp. 483–486, 5 figs. Relation between full-load power factor on number of poles of induction motor.

The Use of Central Station Power in Mines and Steel Plants, K. A. Pauly. Gen. Elec. Rev., vol. 24, no. 6, June 1921, pp. 479–483. Notes on choice of frequency.

Superpower. Clydes Mill Station of the Clyde Valley Power Co. Elecn., vol. 86, no. 2246, June 3, 1921, pp. 686–689, 5 figs. Interconnection of steam-electric plants in and around Glasgow, Scotland.

The Superpower System—Its Scope and Relation to the United States Government, S. W. Murray. Nat. Elec. Light Assn. Bul., vol. 8, no. 6, June 1921, pp. 335–341, 1 fig. Legal, financial and economical considerations.

CHUCKS

Magnetic. Magnetic Chucks—VIII, Ellsworth Sheldon. Am. Mach., vol. 54, no. 22, June 2, 1921, pp. 945–948, 9 figs. Description of Persons-Arter chuck.

COAL

Carbonization. The Assay of Coal for Carbonization Purposes: A New Laboratory Method, Thomas Gray and James G. King. Dept. Sci. & Indus. Research (Fuel Research Board) technical paper no. 1, 1921, 12 pp., 3 figs. 1 on supp. plate. Includes table giving results of duplicate distillations of ten samples of coal, illustrating difference between yields of various products from different classes of coal.

Low-Grade. Australia's Brown-Coal Power Scheme. U. S. Dept. of Commerce, Commerce Reports, no. 117, May 20, 1921, pp. 1029–1031. Steaming value of brown coal is estimated at 50 per cent of that of black coal. Investigation of briquetting processes.

COAL BREAKERS

6000-Ton. Woodward Breaker Sizes and Prepares Six Thousand Tons of Anthracite Per Day, Dever C. Ashmead. Coal Age, vol. 19, no. 19, May 12, 1921, pp. 851–856, 10 figs. Types for sprinkling shakers and guarding shafts. Steel frame and glass walls. Chestnut washed in two sizes.

COAL CLEANING

Dry Process. Dry Cleaning of Coal by Means of Tables, Edward O'Toole. Am. Iron & Steel Inst., advance paper, May 27, 1921, 28 pp., 23 figs. Results of table tests of Indiana and Illinois coals.

[See also COAL WASHING.]

COAL STORAGE

Railways. Railways Lack Policy Toward Coal Storage Development. Ry. Rev., vol. 68, no. 22, May 28, 1921, pp. 810–819, 4 figs. Report of committee on coal storage submitted at Thirteenth Annual Convention of Int. Ry. Fuel Assn.

COAL TIPPLES

Steel. Hillsboro Wood Tipple Replaced by Steel While Shaft is Hoisting Coal, John A. Garcia. Coal Age, vol. 19, no. 19, May 12, 1921, pp. 857–860, 6 figs. Steel structure equipped with pendulum-hung three-track shaker screen, weigh pan, picking table, loading boom and like equipment.

COAL WASHING

Froth Flotation. Froth Flotation as Applied to the Washing of Industrial Coal, Ernest Bury, Walter Broadbridge and Alfred Hutchinson. Can. Min. Jl., vol. 42, no. 20, May 20, 1921, pp. 405–410, 4 figs. Also in Iron & Steel of Canada, vol. 4, no. 4, May 1921, pp. 112–119, 4 figs. Results of tests. Economic aspect of process. Paper read before Instn. Min. Engrs.

In Flotation Process Fine Coal Attaches Itself to Oil and Bubbles, Thus Floating Away with Froth, E. G. Hill. Coal Age, vol. 19, no. 22, June 2, 1921, pp. 993–995, 3 figs. Cleaning of coal by froth flotation.

COKE

Briquets. Tests with Substitute Fuels. (Versuche mit Ersatzbrennstoffen), W. Grunow. Gesundheits-Ingenieur, vol. 44, no. 18, Apr. 30, 1921, pp. 208–212, 1 fig. Results of heating tests carried out with coke briquets made from cinder and admixture of tar showed them to be poorly adapted to house-heating boilers but well adapted to Dutch-tile stoves.

Metallurgical. Study of the Efficient Use of Metallurgical Cokes (Contribution a l'étude de la valeur des cokes métallurgiques), G. Deadrière. Revue universelle des Mines, vol. 9, no. 2, April 15, 1921, pp. 93–107. Writer terms "use value" of a fuel the price which must be paid for fuel when it is substituted by another fuel, in order to effect with the former the same industrial operation that is performed with latter. Formula for use values of metallurgical cokes is developed.

COKE BREEZE

Utilization. Value of Mixtures of—Coke Breeze and Bituminous Coal as Fuel for a Hand-Fired Boiler, John Blizard and James Neil. U. S. Dept. of Interior, Reports of Investigations, Bur. of Mines, serial no. 2244, May 1921, 27 pp., 3 figs. Tests carried out at request of Chamber of Commerce of Pittsburgh in order to determine steaming value of coke breeze as fuel when mixed with Pittsburgh coal and fired by hand, and to see whether mixture when burnt would give off an objectionable quantity of smoke.

COKE OVENS

By-Product. By-Product Coke Ovens and Their Relation to our Fuel Supply, E. B. Elliott. Jl. Am. Soc. Heat. & Vent. Engrs., vol. 26, no. 4, May 1921, pp. 381–400, 6 figs. Relative efficiencies in furnaces of coke and coal.

By-Products of Coal Distillation. Process of Extraction and Installations of Marine and d'Homécourt, Forging and Steel Manufacturing Co. at Boucau Works, France (Les produits de distillation de la houille. Procédés d'extraction et installations de la Cie des Forges et Aciéries de la Marine et d'Homécourt aux usines du Boucau (Basses-Pyrénés), A. Grebel. Génie Civil, vol. 78, no. 22, May 28, 1921, pp. 449–454, 15 figs. partly on supp. plate. Benzol recovery and tar distillation.

The Piron By-Product Coke Ovens. Iron Age, vol. 107, no. 23, June 9, 1921, pp. 1531–1533, 3 figs. Italian vertical downward combustion type. Installation at plant of Woodward Iron Co., Woodward, Ala.

COKE PLANTS

By-Products of. Developments in the Recovery and Treatment of By-Products from Carbonization of Coal (L'évolution dans la récupération et le traitement des sous-produits de la carbonisation de la houille), Ch. Berthelot. Chimie & Industrie, vol. 5, nos. 4 and 5, April and May 1921, pp. 384–397, 23 figs., and 508–517, 12 figs. Study of recent developments and possibilities in increasing recovery of ammonia sulphate and benzol. Methods for recovery and treatment of benzol.

COMBUSTION

Control. Exhibition of Apparatus for Controlling Combustion (Compte rendu de l'exposition d'appareils servant au controle de la chauffe), Pierre Appell. Chaleur et Industrie, vol. 2, no. 4, April 1921, pp. 177–183, 10 figs. Classification and description of principal types. Exposition was organized under auspices of Société des Ingenieurs civils de France and Société d'Encouragement pour l'Industrie nationale. (To be continued.)

Measuring Combustion (La comburimétrie industrielle), M. Andre Grebel. Chaleur et Industrie, vol. 2, no. 4, April 1921, pp. 191–195, 2 figs. Description of Grebel-Velter comburimeter. (To be continued.)

The Scientific Control of Combustion, H. T. Ringrose. Iron & Steel Inst., annual meeting, May 5–6, 1921, advance paper no. 8, 9 pp., 5 figs. Use of recording apparatus for controlling combustion.

Draft Influence. Draft and CO_2 Influence on Evaporation, James T. Beard, Jr. Power, vol. 53, no. 20, May 17, 1921, pp. 775–777, 3 figs. Graphs showing relation between combustion rate and draft for various fuels.

COMPRESSED AIR

Measurement. Measuring Compressed Air Consumption in Pneumatic Tools, M. Piette. Colliery Guardian, vol. 121, no. 3149, May 6, 1921, p. 1315, 3 figs. Apparatus consisting of a venturi tube 1 in. in diameter and provided with constriction. For measuring compression of air differential gage is mounted on venturi tube.

Metering. The Metering of Compressed Air, John L. Hodgson. Mech. World, vol. 69, no. 1794, May 20, 1921, pp. 387–388, 10 figs. Installation in gold mines at Witwatersrand, So. Africa. Paper read before Midland Inst. Min., Civil & Mech. Engrs.

CONCRETE

Alkali Action. Progress in Investigation of Alkali Action on Concrete, E. C. Bebb. Eng. World, vol. 18, no. 6, June 1921, pp. 391–393. Investigations of advisory committee appointed by Bur. of Standards Reclamation Service, Drainage Investigations Office of Dept. of Agriculture and Portland Cement Assn.

Consistency. A Comparison of the Results of the Slump Test and the Flow Table in the Measurement of the Consistency of Concrete, W. L. Schwalbe. Am. Soc. for Testing Matls., paper of annual meeting, June 21–24, 1921, 6 pp., 4 figs. It is concluded that relative consistencies are more truly indicated by flow table for greater range of consistencies than by slump test.

Crusher Screenings. Effect of Crusher Screenings in Concrete. Can. Engr., vol. 40, no. 21, May 26, 1921, pp. 500–502, 1 fig. Tests carried out by Milton Hersey Co., Montreal, for Crushed Stone Corporation Dundas, Ont. Increase in strength of concrete through use of up to 20 per cent of crusher screenings is reported.

Mixer. Pneumatic Concrete Mixer for Jap Tunnel. Public Works, vol. 50, no. 22, May 28, 1921, pp. 452–454, 1 fig. Special compressed-air machine designed for lining Imperial Japanese Government Railways tunnel.

Porete. Porete—A New Kind of Concrete, E. Walter. Concrete Products, vol. 20, no. 5, May 1921, pp. 19–21, 5 figs. Building product developed by Porete Mfg. Co. which is much lighter in weight than ordinary concrete, weighing from 50 to 55 lb. per cu. ft.

Proportioning Aggregates. A Proposed Method of Estimating the Density and Strength of Concrete and of Proportioning the Materials by the Experimental and Analytical Consideration of the Voids in Mortar and Concrete, Arthur N. Talbot. Am. Soc. for Testing Matls., paper of annual meeting, June 21–24, 1921, 29 pp., 9 figs. Characteristic mortar curves giving relation between mortar voids and ratio of fine aggregate to cement, both for basic water content and for water contents in excess of this. Analytical relations developed from characteristic curves for determining proportions of cement, fine aggregate and coarse aggregate for concrete of required density and strength.

Sea-Water Action. Effect of Sea Water on Concrete Structures. Cement & Eng. News., vol. 33, no. 5, May 1921, pp. 29–30, 1 fig. Experience with piers at Annapolis Royal, Nova Scotia.

Specifications. German Specifications for Concrete (Die Gütevorschriften für Beton), B. Löser. Bauingenieur, vol. 2, no. 9, May 15, 1921, pp. 229–233, 5 figs. From results of investigations writer concludes that officially prescribed testing method for soft and liquid concrete is unsuitable and leads to false conclusions.

Strength. Effects of Organic Impurities on Concrete. Public Works, vol. 50, no. 21, May 21, 1921, pp. 425–426. Investigations at Lewis Inst., Chicago. Minute quantities of tannic acid reduce strength one half. Surface loam always reduces strength. From proceedings Am. Soc. for Testing Matls.

Testing. Report of Committee C-9 on Concrete and Concrete Aggregates. Am. Soc. for Testing Matls., paper of annual meeting, June 21–24, 1921, 19 pp. Proposed tentative methods for making compression tests of cement concrete, test for organic impurities in sands, test for sieve analysis of aggregates, and for securing specimens of hardened concrete from structure; also proposed tentative specifications for concrete aggregates.

Tests. Influence of the Grain Composition of the Aggregates of Gravel-Concrete Mixtures on Compressive Strength and Elasticity (Der Einfluss der Kornzusammensetzung der Zuschlagstoffe von Kiesbeton-Mischungen auf die Druckfestigkeit und -Elastizität), Josef Kortlang. Bauingenieur, vol. 2, no. 9, May 15, 1921, pp. 239–243, 5 figs. Results of experiments show that compressive strength is dependent upon water cement and cement ratios and the total surface of aggregates per unit.

Water Content. Mathematical Determinations of Water Content of Mortars and Concrete, According to the New Theories on Their composition and on the Rôle Played by Their Various Elements (Le dosage mathématique, en eau, des mortiers et bétons, d'après les nouvelles théories sur leur composition et sur le rôle de leurs divers éléments), J. Boudet. Vie technique & industrielle, vol. 2, no. 19, April 1921, pp. 39–45, 4 figs. Graphs.

CONCRETE CONSTRUCTION

Developments. New Methods Relating to Concrete Construction. Concrete & Constructional Eng., vol. 16, no. 5, May 1921, pp. 311–317, 15 figs. Inventions relating to construction of walls, wall ties, slabs, etc.

Technology. Some Problems in Concrete Construction, W. K. Hatt. Mun. & County Eng., vol. 60, no. 5, May 1921, pp. 182–187. Review of principles developed from results of various investigators.

CONCRETE, REINFORCED

Wood Reinforcement. Wood Reinforcements of Cement (Le béton armé de bois), M. Levatel. Outillage, vol. 5, no. 10, Mar. 10, 1921, pp. 283–284, 10 figs. Experiments show that wood reinforcements are effective, wood being preserved perfectly for indefinite time.

CONDENSERS, STEAM

Water Films. The Water Film on Evaporating and Condensing Tubes, P. H. Parr. Engr., vol. 131, no. 3413, May 27, 1921, pp. 559–561. Internal resistance of water film.

CONDUITS

Steam Pipe. Steam Conduit for Toronto's New Union Station. Contract Rec., vol. 35, no. 22, June 1, 1921, pp. 551–552, 4 figs. Two pipe lines in concrete tunnel convey steam from power house, several blocks distant. Provision for removal of seepage.

CONNECTING RODS

Machining Operations. Machining Connecting Rods. Eng. Production, vol. 2, no. 35, June 2, 1921, pp. 681–683, 6 figs. Jigs and tools for accurate production.

Rolls-Royce. The Rolls-Royce Connecting Rods, Ferd H. Colvin. Am. Mach., vol. 54, no. 24, June 16, 1921, pp. 1041–1043, 7 figs. Machining methods.

COOLING TOWERS

New Type. A New Type of Water Cooling Tower. Beama, vol. 8, no. 5, May 1921, p. 418. Tower recently erected at government electric station in Dresden, Germany. Air and water do not flow on counter-current principle, but air enters cooler horizontally while water falls vertically.

COPPER

Thermal Expansion. Thermal Expansion of Copper and Some of Its Important Industrial Alloys, Peter Hidnert. U. S. Dept. of Commerce, Scientific Papers of Bur. of Standards, no. 410, Mar. 21, 1921, pp. 91–159, 43 figs. Data on thermal expansion of 128 samples of copper and its important industrial alloys of various compositions, heat treatments, mechanical treatments, etc. Samples were examined from room temperature to about 300 deg. cent.

CORES

Core Oils. Tests Show the Quality of Core Oils, R. F. Harrington. Foundry, vol. 49, no. 11, June 1, 1921, pp. 447–448, 3 figs. Tests used by manufacturers of core oil to determine character of various ingredients are described. Effect of core oil varied by use of dry or wet sand.

CORROSION

Iron in Concrete. The Corrosion of Iron and Steel with Special Reference to Reinforced Concrete, J. Newton Friend. Concrete Inst. Trans., vol. 9, Apr. 1921, pp. 1–15 and (discussion) pp. D15–D20, 3 figs. It is shown that preservation of iron in concrete may be effected in one or more of three ways, namely by complete exclusion of air, of water, and by rendering concrete sufficiently alkaline to place it within the protective area. Suggestions are offered.

CRANES

Locomotive. Electrically Driven Locomotive-Lifting Crane (Elektrisch betriebene Lokomotivhebekrane), Ernst Schwarz. Zeit. des Vereines deutscher Ingenieure, vol. 65, no. 22, May 28, 1921, pp. 574–576, 4 figs. Crane of Hungarian Car & Machine Factory in Györ and AEG Union Electrical Co., Vienna, consisting of two coupled traveling cranes, each having two hoist trolleys. Details of mechanical and electrical equipment; control; original form of connection plug.

CUTTING TOOLS

Design. Metal Cutting Tools—X and XI, A. L. DeLeeuw. Am. Mach., vol. 54, nos. 21 and 23, May 26 and June 9, 1921, pp. 897–902, 13 figs., and 985–990, 13 figs. May 26. Notes on design of milling cutters, gear cutters, duplex cutters and various types of hobs. June 9: Cutter sharpening; characteristics of cup and disk wheels; importance of correct angles; cutter grinders; hob grinding.

Working Pressures. Origin and Calculation of Working Pressure with Single-Cutter Tools Based on Results of Recent Experiments (Entstehung und Berechnung der Zerspannungswiderstände bei einschneidigen Werkzeugen auf Grund der Ergebnisse neuerer Versuchsreihen), Ernst J. Wild. Betrieb, vol. 3, no. 16, May 10, 1921, pp. 467–472, 5 figs. Critical investigation of results of experiments carried out in recent years on the behavior of single-cutter tools in turning and planing. Based on conclusions reached, new formulas are derived for the exact precalculation of the cutting forces, taking into consideration the shape of tool.

D

DIESEL ENGINES

Compression. The Compression Line in Diesel-Engine Cards (Ueber den Verlauf der Kompressionslinie bei Dieselmotoren), Arthur Balogh. Wirtschaftsmotor, no. 3, Mar. 1921, pp. 19–20, 8 figs. Results of experimental tests carried out on a single-cylinder Diesel engine to determine course of compression line of indicator cards.

Oil-Fuel Injection. Injection and Combustion of Fuel-Oil, C. J. Hawkes. Motorship, vol. 6, no. 6, June 1921, p. 483, 3 figs. Experiments with solid injection and air-blast in marine Diesel engines. (Continuation of serial.)

Standardization. Standardized Diesel Engines—IV, H. R. Setz. Mar. Eng., vol. 26, no. 6, June 1921, pp. 471–476, 11 figs. Description of engine with automatic valve-port scavenging arrangement.

Tar Oil as Fuel. The Use of Tar Oil in Diesel Engines (Die Verarbeitung von Teeröl im Dieselmotor), W. Riehm. Zeit. des Vereines deutscher Ingenieure, vol. 65, no. 20, May 14, 1921, pp. 522–526, 18 figs. Means whereby safe starting up of cold engine, reliable ignition and complete combustion under all load conditions can be obtained.

DRAWINGS

Filing. Indexing and Filing Industrial Drawings, L. H. Park. Iron Age, vol. 107, no. 22, June 2, 1921, pp. 1447–1449, 1 fig. Systems used by prominent engineers and manufacturers.

DREDGING

Tests. Tests of Dredge Pump Operation for Hydraulic Fill, Ivan E. Houk. Eng. News-Rec., vol. 86, no. 24, June 16, 1921, pp. 1034–1037, 3 figs. Velocities and power consumption decreased as friction head and solids increased.

DRILLING MACHINES

Radial. Carlton Heavy-Duty Ball Bearing Radial Drill Machine, J. V. Hunter. Am. Mach., vol. 54, no. 21, May 26, 1921, pp. 908–911, 6 figs. Heavy-duty, geared radial drilling machine made by Carlton Machine Tool Co., Cincinnati.

Tests. Investigations on Drilling Machines (Untersuchungen an Bohrmaschinen), S. ter Ohanessian. Werkstattstechnik, vol. 15, no. 9, May 1, 1921, pp. 241–244, 12 figs. Tests carried out at laboratory of Technical Academy of Charlottenburg with two motor-driven bench, two hand and one upright drilling machines, for determination of efficiency, etc.

DRILLS

Twisted vs. Twist. The Strength of Twisted Drills. Machy. (Lond.), vol. 18, no. 452, May 26, 1921, pp. 244–247, 15 figs. Data, comprising a series of micro-etchings and test results, obtained by J. Beardshaw & Sons, Ltd., Baltic Steel Works, Sheffield and representing outcome of extensive investigation to ascertain strength of twisted drills as compared with ordinary twist drills.

DROP FORGING

Plants. Fuel Economy of a Drop Forge Plant, N. A. Craigue and C. H. L. Thompson. Iron Age, vol. 107, no. 23, June 9, 1921, pp. 1521–1525, 6 figs. Tests on steam consumption of drop-forging hammers.

DUST

Cloud-Condensation Apparatus. The Shimizu-Wilson Cloud Condensation Apparatus. Engineering, vol. 111, no. 2892, June 3, 1921, p. 692, 2 figs. Apparatus for measuring dustiness of air.

E

EDUCATION, ENGINEERING

Industrial Training. Requirements of the Engineering Industries and the Education of Engineers, Magnus W. Alexander. Mech. Eng., vol. 43, no. 6, June 1921, pp. 391–395 and 397. Developments in organization of coöperative engineering courses in connection with manufacturing plants. Plan organized at Mass. Inst. of Technology and Lynn Works of Gen. Elec. Co. During their assignments at works, students are subject to usual rules and regulations applying to employees of Gen. Elec. Co.

EDUCATION, INDUSTRIAL

Steel Industry. Educational Work in the Wire Industry, Charles R. Sturdevant. Iron Age, vol. 107, no. 22, June 2, 1921, pp. 1460–1462. Courses

on salesmanship, Americanization and for foremen, being given by Am. Steel & Wire Co., Cleveland. Paper read before Am. Iron & Steel Inst.

ELECTRIC DRIVE

Air Compressors. Electrically Driven Centrifugal Compressors, R. S. Sage. Gen. Elec. Rev., vol. 24, no. 6, June 1921, pp. 559–553, 6 figs. Suitability of this load for central stations.

Motor Drives for Air Compressors, Gordon Fox. Power, vol. 53, no. 20, May 17, 1921, pp. 778–779, 3 figs. Types of air compressor, their limitations. power requirements and operating characteristics. Motors to use for different applications.

Slow Speed Motors and Their Application to Reciprocating Air Compressors, R. O. Joslyn. Armour Engr., vol. 12, no. 4, May 1921, pp. 226–239, 6 figs. Operation characteristics of typical installation.

Flour Mills. Electric Drive for Flour and Grist Mills, W. T. Edgell, Jr. Gen. Elec. Rev., vol. 24, no. 6, June 1921, pp. 542–546, 3 figs. Operating data obtained in existing installations.

Machine Shops. Electric Drive for Machine Shops, B. S. Pero. Gen. Elec. Rev., vol. 24, no. 6, June 1921, pp. 528–529, 2 figs. Types of motors used.

Machine Tools. Installation of Motor Drives on Old Tools, J. H. Vincent. Am. Mach., vol. 54, no. 23, June 9, 1921, pp. 100–1001, 3 figs. Expedients resorted to in railroad shop to provide individual motor drive for old planer and boring mill.

Oil Fields. Extension of Electric Power Service Into the Oil Fields, W. G. Taylor. Gen. Elec. Rev., vol. 24, no. 6, June 1921, pp. 535–538, 5 figs. Survey of developments.

Refrigerating Plants. Refrigeration Load. A. R. Stevenson, Jr. Gen. Elec. Rev., vol. 24, no. 6, June 1921, pp. 569–571, 2 figs. Typical load curves of ice plants.

Rolling Mills. Sheet Rolling Mills at Baltimore. Iron Age, vol. 107, no. 23, June 9, 1921, pp. 1535–1538, 7 figs. Top rolls of roughing mills driven by independent motor.

Skip Hoists. Electric Drive for Small Automatic Self-Dumping Skip Hoists, R. H. McLain and C. B. Connely. Gen. Elec. Rev., vol. 24, no. 6, June 1921, pp. 530–535, 13 figs. Notes on design of installations.

Steel Mills. Blooming Mill Motor Drive, B. M. Jones. Iron Age, vol. 107, no. 21, May 26, 1921, pp. 1386–1387, 2 figs. Replacing steam by electric drive on large reversing blooming mill at plant of Bethlehem Steel Co.

Load Conditions in Steel Mills, J. D. Wright and L. C. Moseley. Gen. Elec. Rev., vol. 24, no. 6, June 1921, pp. 487–490, 8 figs. Typical load curves.

Woodworking Industry. Motor Drive in the Woodworking Industry, F. H. Penney and E. L. Bamforth. Gen. Elec. Rev., vol. 24, no. 6, June 1921, pp. 554–557, 5 figs. Types of electrically driven machines used in wood-working industry.

ELECTRIC FURNACES

Crucible vs. Electric vs. Crucible Furnaces, H. W. Gillet and T. H. A. Eastick. Metal Industry (N. Y.), vol. 19, no. 6, June 1921, pp. 240–242. Opinions of Bur. of Mines experts on opposite sides of question.

ELECTRIC PLANTS

Interconnection. Interconnection Problems and Economies, E. P. Peck and Harry J. Burton. Elec. World, vol. 77, no. 22, May 28, 1921, pp. 1238–1240. Symposium. Titles of papers are: Charts for Quick Solution of Line-Drop Problems; Conditions that Must Be Watched When Inter-connecting Small Plants; and Economic Benefits Derived from Energy Interchange.

Protective Equipment. Protection of Power-Station Equipment, Edgar P. Slack. Power, vol. 53, no. 23, June 7, 1921, pp. 920–923, 3 figs. National Electrical Code as applied to power-station equipment.

ELECTRIC WELDING

Cast Steel. Repairing a Gold Dredge Bull Gear, C. M. Romanowitz. Eng. & Min. Jl., vol. 111, no. 25, June 18, 1921, pp. 1030–1031, 3 figs. Repairing cast-steel gear of about 14 ft. 2 in. in diameter and 15-in. face.

ELECTRIC WELDING, ARC

Automatic. Automatic Arc Welding, H. L. Unland. Gen. Elec. Rev., vol. 24, no. 6, June 1921, pp. 583–586, 5 figs. Apparatus developed for automatic welding by electric arc.

Kjellberg Process. Electric Arc Welding (La soudure électrique à l'arc), M. Lebrun. Revue de Métallurgie, vol. 18, no. 4, April 1921, pp. 201–212, 11 figs. Tests of Kjellberg process at Naval College of Greenwich by Anglo-Swedish Elec. Welding Co. Kjellberg process consists in stabilizing direction of arc by surrounding electrode with non-conducting slightly fusible material. Arc is thus prevented from flickering.

ELECTRIC WELDING, RESISTANCE

Modern Machines. Recent Progress in the Construction of Electric Welding Machines (Neuere Fortschritte im Bau elektrischer Schweissmaschinen), Albert Neuburger. Werkstattstechnik, vol. 15, no. 9, May 1, 1921, pp. 250–255, 8 figs. Details of various improved types of machines for spot, butt and seam welding.

Tests. Resistance Electric Welding (La soudure électrique par résistance), J. Paturel. Vie technique & industrielle, vol. 2, nos. 19 and 20, April and May 1921, pp. 24–26, 5 figs., and 137–139, 11 figs. Tests on aluminum and steel articles.

ENAMELS

Copper. Some Data on the Composition of Arsenic Enamels for Copper, B. T. Sweely. Jl. Am. Ceramic Soc., vol. 4, no. 5, May 1921, pp. 350–356. Methods of application by wet slushing.

EVAPORATORS

Regenerative Compressor. G-R Regenerative Compressor. Power, vol. 53, no. 20, May 17, 1921, p. 777, 1 fig. Apparatus designed for installation on Reilly evaporators. Compressor is essentially jet flow compressor that entrains and compresses by means of live steam part of vapor produced by evaporator, and this entrained vapor is in turn led to evaporator coils together with boiler steam.

F

FABRICS

A.S.T.M. Committee Report. Report of Committee D-13 on Textile Materials. Am. Soc. for Testing Matls., paper of annual meeting, June 21–24, 1921, 8 pp. Proposed tentative definitions of terms relating to mechanical fabric and proposed tentative specifications for imperfections and tolerances for square-woven tire builder fabric.

FACTORIES

Building Construction. Can I Put Up That Building More Cheaply? J. Morrow Oxley. Contract Rec., vol. 35, no. 9, Mar. 2, 1921, pp. 218–222, 8 figs. Cost analysis of structural design of standard factory type.

FACTORY MANAGEMENT.

See INDUSTRIAL MANAGEMENT.

FANS, CENTRIFUGAL

Design. Some Developments in Centrifugal Fan Design, F. W. Bailey and A. A. Criqui. Jl. Am. Soc. Heat. & Vent. Engrs., vol. 27, no. 4, May 1921, pp. 375–380, 7 figs. Comparison of static efficiencies of forward and double-curved-blade types of fans.

FATIGUE

Industrial. Fatigue and Efficiency in Iron and Steel Works—VII, H. M. Vernon and E. A. Rusher. Eng. & Indus. Management, vol. 5, no. 18, May 5, 1921, pp. 519–522. Health of steel workers. Abstract from Report No. 5 of British Indus. Fatigue Research Board.

Fatigue in the Boot and Shoe Industry, J. Loveday and S. H. Munro. Eng. & Indus. Management, vol. 5, no. 19, May 12, 1921, pp. 541–543, 10 figs. Records given in report to British Indus. Fatigue Research Board.

FIREBRICK

Spalling. Report of Committee C-8 on Refractories. Am. Soc. for Testing Matls., paper of annual meeting. June 21–24, 1921, 4 pp. Proposed tentative method of test for resistance of fireclay brick to spalling action.

FLAX

Scutching Machine. Flax Scutching Machine. Engineering, vol. 111, no. 2890, May 20, 1921, pp. 614–616, 7 figs. Combined flax-breaking and scutching machine invented by M. Swynghedauw of Motteville, France.

FLOW OF OIL

Pipes. The Flow of Petroleum Oils Through Pipes, W. A. Thomas. Oil News, vol. 9, no. 10, May 20, 1921, pp. 33–34. Tables of coefficients in formulas.

FLUE-GAS ANALYSIS

Excess-Air Determination. Determination of Excess Air from Flue Gas Analysis, R. Brown. Combustion, vol. 4, no. 6, June 1921, pp. 24–25, 2 figs. Chart and derivation of formula used in making it.

FORGE PLANTS

Erie. War Plant of Erie Forge & Steel Co., Sidney G. Koon. Iron Age, vol. 107, no. 24, June 16, 1921, pp. 1595–1603, 12 figs. Plant developed and built by U. S. Navy Dept. under emergency legislation of Oct. 1917.

FOUNDRIES

Layout. Completes Revision of Foundry, George H. Manlove. Foundry, vol. 49, no. 11, June 1, 1921, pp. 426–429, 8 figs. Layout of Chicago Steel Foundry Co. providing for straight-line traveling of products.

Power Plants. Power for the Toledo Machine and Tool Co. Power Plant Eng., vol. 25, no. 12, June 15, 1921, pp. 595–599, 8 figs. Plant furnishes power, light and heat necessary for operation of large foundry.

FUELS

Garbage. The Economic Utilization of House Garbage as Fuel (Die Vorbedingungen für die wirtschaftliche Verwertung des Hausmülls als Brennstoff), Jakob Bodler. Zeit. des Bayerischen Revisions Vereins, vol. 25, nos. 7 and 8, Apr. 15 and 30, 1921, pp. 49–52 and 57–62, 5 figs. Suggestions for preliminary treatment of garbage with view to obtaining a good combustion.

FURNACES

Flame Propagation. Examination of Theory of Flame Furnaces Based on Laws of Hydraulics (Essai d'une théorie des fours a flammes basée sur les lois de l'hydraulique), W. E. Groume-Grjimailo. Revue universelle des Mines, vol. 9, no. 2, April 15, 1921, pp. 132–144 15 figs. Fundamental idea is that circulation of flames in furnace is identical with movement of light liquid in heavy liquid.

G

GAGES

Screw. The Manufacture of Hardened Screw Gauges. Eng. Production, vol. 2, no. 34, May 26, 1921, pp. 644–645, 3 figs. Machines and processes employed.

GAS ENGINES

Measurement of Gas and Air. Measurement of the Suction Gas and Air Volumes in Gas Engines (Messung der von Gasmaschinen angesaugten Gas- und Luftmengen), K. Schreber. Oel- u. Gasmaschine, vol. 18, no. 5, May 1921, pp. 72–73. Results of investigation show that, with use of certain precautionary measures, it is possible with aid of a nozzle to carry out measurements for determining economy of gas engines.

GASOLINE

Cracking Processes. Manufacture of Motor Spirit by "Cracking" Processes. Chem. Age (Lond.), vol. 4, no. 101, May 21, 1921, pp. 578–580. Manufacture of gasoline by pyrolitic decomposition of higher boiling hydrocarbons.

Specifications. Report on Low Test Gasoline Specifications. U. S. War Dept., Air Service Information Circular, vol. 2, no. 165, May 1, 1921, 4 pp.

GEARS

Blank Manufacture. An Improved Method of Making Steel Gear and Wheel Blanks, George Atwell Richardson. Am. Mach., vol. 54, no. 23, June 9, 1921, pp. 981–984, 13 figs. Manufacture of high-grade steel gear blanks in hydraulic ram for production work.

Design. Odontograph for Layout of 20-Degree Gear Teeth, J. L. Williamson. Machy. (N. Y.), vol. 27, no. 10, June 1921, pp. 929, 1 fig. Table giving calculated valuation of constant.

Involute. Slip of Involute Gear Teeth. A. B. Cox. Am. Mach., vol. 54, nos. 21 and 22, May 26 and June 2, 1921, pp. 913–917, 4 figs., and 951–955, 9 figs. Gear efficiency increased and wear decreased by using large numbers of teeth. Shorter addendum reduced slip. Friction losses increase with increases in angle of obliquity. Graphs. Diagrams for internal-gear formulas. (To be continued.)

The Evolution of the Involute Gear Tooth—V, A. Fisher. Machy. (Lond.), vol. 18, no. 453, June 2, 1921, pp. 273–276, 8 figs. Study of contact conditions.

Laminated. The Manufacture of Laminated Gears. Eng. Production, vol. 2, no. 34, May 26, 1921, pp. 653–655, 7 figs. Practice at works of Laminated Gears, Ltd., Sheffield, England.

Machining Operations. Machining a Large Gear Blank on the Automatic, J. H. Moore. Can. Machy., vol. 25, no. 21, May 26, 1921, pp. 71–74, 12 figs. Attachments used. Tool layouts for gear blanks, hubs and spark-plug shells.

Spiral. Chart for Selecting Spiral Gears. Machy. (Lond.), vol. 18, no. 449, May 5, 1921, pp. 141–143, 1 fig. Chart prepared from standard formulas.

GRINDING MACHINES

Cylinder. Cylinder Grinding Machine. Engineering, vol. 111, no. 2892, June 3, 1921, pp. 676–678, 20 figs. Machines manufactured by Heald Machine Co., Worcester, Mass.

GUN METAL

Properties. Reviews Properties of Gunmetal, Joseph Horton. Foundry, vol. 49, no. 11, June 1, 1921, pp. 436–439. Compositions and physical properties called for in different specifications are compared and views of number of investigators on effects of various metals and heat treatments are cited.

GUNS

Radially Expanded. Elastic Strength of Radially Expanded Guns, W. H. P. Blandy. U. S. Naval Inst. Proc., vol. 47, no. 220, June 1921, pp. 883–908, 14 figs. Process of gun construction by radial expansion was described in U. S. Naval Inst. Proc. for Dec. 1920. In present article elastic strength of radially expanded gun is computed analytically and compared with similarly computed strengths of other guns.

H

HANGARS

Reinforced-Concrete. Reinforced Concrete Hangars. Concrete Constructional Eng., vol. 16, no. 5, May 1921, pp. 318–320, 4 figs. Hangar recently built at Lucon Vendée, France. Design consists of arch 176 ft. high internally, 186 ft. externally, 362 ft. wide and 733 ft. long. Translated from Génie Civil.

HEAT TRANSMISSION

Research. Apparatus for Testing Insulating Materials, F. B. Rowley. Jl. Am. Soc. Heat. & Vent. Engrs., vol. 26, no. 4, May 1921, pp. 469–474, 8 figs. Adaptations of hot-box methods of testing heat transmission.

Heat Transmission Investigations, A. J. Wood and E. F. Grundhofer. Jl. Am. Soc. Heat. & Vent. Engrs., vol. 26, no. 4, May 1921, pp. 453–462, 1 fig. Results of study and experimentation on heat transmission through corkboard and air spaces. Work undertaken at Engineering Experiment Station, Pennsylvania State College.

HEATING, ELECTRIC

Factories. Air Heating by Electricity in Swiss Fac-

tory (Réchauffeur d'air électrique, à accumulation). Génie Civil, vol. 78, no. 18, April 30, 1921, pp. 376–377, 2 figs. Heater has capacity of 3300 kw.

HEATING, GAS

Coal versus. The Application of Gas to Space Heating, Thomson King. Jl. Am. Soc. Heat. & Vent. Engrs., vol. 26, no. 4, May 1921, pp. 421–434, 10 figs. Comparative costs of heating by gas and by coal.

HEATING, HOT-WATER

Piping. Circulation Problems in Hot-Water Heating, A. W. Luck. Jl. Am. Soc. Heat. & Vent. Engrs., vol. 26, no. 4, May 1921, pp. 409–416, 7 figs. Typical piping methods.

HEATING, STEAM

Gravity Systems. Fractional Distribution in Two Pipe Gravity Steam-Heating Systems, Alphonse A. Adler and James A. Donnelly. Jl. Am. Soc. Heat & Vent. Engrs., vol. 26, no. 4, May 1921, pp. 437–452, 4 figs. Typical devices for gravity return.

HOISTING ENGINES

Mine. A Large American Mine Winding Engine. Engr., vol. 131, no. 3412, May 20, 1921, pp. 540–542 and 544, 7 figs. Four-cylinder cross-compound condensing machine with drum 30 ft. diameter for raising 10-ton loads with rope speed of 3200 ft. per min. from depths of 6600 ft. to 8600 ft.

HOUSES

Stucco. Back-Plastered Stucco House Construction Concrete, vol. 18, no. 6, June 1921, pp. 274–278, 12 figs. Recommendations prepared by Committee of Am. Concrete Inst.

HOUSES, CONCRETE

Economic Construction. "Double C" Elements for Economic Construction of Buildings (Agglomérés en éléments dits "double C" pour la construction economique des bâtiments). Génie Civil, vol. 78, no. 18, April 30, 1921, p. 379, 3 figs. Concrete slabs with projecting members. In erecting wall projecting members are placed end to end and fastened together by suitable reinforcing bar.

England. The Development of Concrete for Housing in England. Concrete, vol. 18, no. 6, June 1921, pp. 279–281, 6 figs. Systems of constructing cavity walls. From Concrete & Constructional Eng.

Unit Dwellings. The One-Piece House, Harry A. Mount. Sci. Am., vol. 124, no. 22, May 28, 1921, pp. 424–425, 4 figs. Simon Lake's scheme for producing ready-to-live-in concrete unit dwellings and transporting them to site.

HOUSING

Industrial. The Present Housing Crisis and Suggested Way Out, John Ihlder. Jl. Engrs. Club of Phila., vol. 38, no. 197, May 1921, pp. 210–205. Government house building in England adopted as necessary for future. Political and economic aspect of housing shortage in U. S.

Mines. Rosita, Mexico, a Carefully Planned City; Pleasing, Comfortable and Hygienic—I, Hjalmar E. Skougor. Coal Age, vol. 19, nos. 22 and 23, June 2 and 9, 1921, pp. 983–987, 8 figs., and 1037–1040, 9 figs. Village for employees at coal mines and by-product plant of Am. Smelting & Refining Co. Each family to have lot 50 ft. square and share in a large community farm.

HYDRAULIC TURBINES

Design. A New Type of Water Turbine. Engr., vol. 131, no. 3411, May 13, 1921, pp. 518–519, 6 figs. Suggests use of continuously curved inner and outer surfaces of revolution for turbine water passages, thus avoiding all sudden changes of curvature.

Calculation of the Moment of Inertia of the Flywheel of a Hydraulic Turbine (Calcul du moment d'inertie a donner aux volants des turbines hydrauliques), P. Cayère. Houille Blanche, vol. 20, no. 51–52, Mar.-April 1921, pp. 57–63, 10 figs. Formulas and graphs.

Governors. Improvements in Hydraulic Turbines, H. Donath. (Neuerungen an Wasserturbinen), Elektrotechnischer Anzeiger, vol. 38, nos. 69–70, 71 and 72, May 4, 5 and 7, 1921, pp. 439–442, 447–448 and 453–455, 17 figs. Details of regulating devices.

Regulation. Regulation of Hydraulic Turbines (Les turbines hydrauliques et leur régulation). Revue genérale de l'Électricité, vol. 9, no. 18, April 30, 1921, pp. 616–623, 7 figs. Survey of developments. (Abstract.) Paper read before Société des Ingénieurs civils de France.

HYDROELECTRIC PLANTS

Canada. Hydroelectric Plant at Weedon, P. Q., for City of Sherbrooke. Elec. News, vol. 30, no. 10, May 15, 1921, pp. 30–31, 3 figs. Plant will develop 4000 hp. and deliver energy at 50,000 volts along transmission line 28 mi. long.

Design. Hydro-Electric Practice—Features of Design, C. Voetsch. Power, vol. 53, no. 21, May 24, 1921, pp. 818–823, 12 figs. Overall efficiency of hydroelectric power system. Effects of main unit sizes upon station efficiency. Importance of specific speed in turbine design. Curves given for checking turbine design or laying out preliminary designs.

Efficiency. How to Increase the Efficiency of Existing Water-Power Plants, Charles M. Allen. Jl. Worcester Polytechnic Inst., vol 24, no. 3, April 1921, pp. 192–200, 1 fig. Graph showing best speed for maximum horsepower at any gate for heads from 25 ft. to 33 ft.

Hydraucone Regainer. The Hydraucone Regainer, Its Development and Applications in Hydroelectric Plants, W. M. White. Mech. Eng., vol. 43, no. 6, June 1921, pp. 375–380 and 419, 17 figs. Device for recovering energy discharged from runner for useful effect on water wheel within limited space available in power-house foundations. Method consists in causing stream flow to impinge upon flat, conical or concave shape, thus changing its direction, and then by means of a gradual diverging envelope placed around this shape to change the velocity head of a fluid entering at high velocity into pressure and low velocity at exit. Results of tests are included.

Spain. Hydroelectric Plants of Guadiaro River, Spain (Les usines hydro-électriques du Guadiaro), Adolphe Weber. Schweizerische Bauzeitung, vol. 77, no. 23, June 4, 1921, pp. 257–258, 4 figs. Corshado plant utilizing waterfall of 120 m. (To be continued.)

Sweden. High Power Hydroelectric Installations (Installations hydro-électriques de grande puissance), A. Tétrel. Electricien, vol. 37, no. 1277, June 1, 1921, pp. 241–247, 9 figs. Central station at Trollhättan, Sweden. (To be continued.)

Underground. An Underground Hydroelectric Plant (Un cas particulier d'usine hydroélectrique souterraine), Paul Basiaux. Revue générale de l'Électricité, vol. 9, no. 19, May 7, 1921, pp. 656–657, 1 fig. Tunnel was constructed for diverting flow of water from Diege River, affluent of Dorgogne in France. Total energy utilized is 200,000 hp.

Water-Main Operation. Hydro-Electric Unit Operated from City Water Main, J. B. Holdcroft. Contract Rec., vol. 35, no. 9, Mar. 2, 1921, pp. 207–210, 4 figs. Installation at Port Alberni, B. C., where high pressure and large pipe capacity permitted water-wheel attachment, operating civic lighting plant.

HYDROGLIDERS

Theory. The Hydroglider—Its Theory and Its Future (L'hydroglisseur, sa théorie, son avenir), F. de Pierrefeu. Vie technique & industrielle, vol. 2, no. 18, Mar. 1921, pp. 511–517, 10 figs. Boat gliding along surface of water by action of air propeller.

I

ICE PLANTS

Toronto. Producing Ice in an Up-To-Date Plant, T. H. Fenner. Power House, vol. 14, no. 8, April 20, 1921, pp. 21–24, 7 figs. Toronto plant with output of 80 tons per day.

IGNITION

Theory. Underlying Principles of Electrical Ignition, Benjamin F. Bailey. Jl. Soc. Automotive Engrs., vol. 8, no. 6, June 1921, pp. 570–576 and 607, 8 figs. Formulas and graphs expressing variations in energy supplied by magneto, produced by changes in engine speed.

INDUSTRIAL MANAGEMENT

Chart of. The Chart of Scientific Management, Robert Stelling. Eng. & Indus. Management, vol. 5, no. 22, June 2, 1921, pp. 622–623, 1 fig. Methods by which economic waste can be eliminated.

Control of Functions. The Control of Function in Industry. Eng. & Indus. Management, vol. 5, no. 21, May 26, 1921, pp. 597–599. Essential features to be considered when planning a scheme for controlling functions, or duties, of a worker in large organization.

Distribution of Work. Factory Management (Die Betriebsleitung des Grossbetriebes), Gustav Wedemeyer. Betrieb, vol. 3, no. 16, May 10, 1921, pp. 482–483. Notes on distribution of work among executive heads.

Instruction Sheets. Proposals for New Factory Instruction Sheets (Entwürfe neuer Betriebsblätter). Betrieb, vol. 3, no. 16, May 10, 1921, pp. 120–121. Proposal of Works Department of German Federation of Technical and Scientific Societies for instruction sheet for installation and care of transmissions; and for fire-prevention measures.

Measurement of Labor Losses. Production Hours—A New Measure of Management, William Leavitt Stoddard. Factory, vol. 26, no. 11, June 1, 1921, pp. 1287–1291, 1 fig. Plan for accurate measurement of labor losses.

Production Systems. Modern Production Methods—XVII, W. R. Basset. Am. Mach., vol. 54, no. 24, June 16, 1921, pp. 1032–1036, 4 figs. Illustrates method of handling abnormal expense.

Planning and Controlling Production in a French Shop, E. Julien. Am. Mach., vol. 54, no. 21, May 26, 1921, pp. 889–893, 13 figs. Engineering department responsible for bills of material. Cylindrical control board saves room. Calculagraph used in work-distributing department.

Routing Materials. Works Administration, Cecil F. Hammond. Eng. Production, vol. 2, no. 34, May 26, 1921, pp. 647–652, 11 figs. Progress system and its relation to works costing.

[See also TIME STUDY.]

INSPECTION

Systems. The Delco Inspection System, Louis Ruthenburg and R. A. Crist. Machy. (N. Y.), vol. 27, no. 10, June 1921, pp. 921–926, 4 figs. Methods used by Dayton Eng. Laboratories Co., for inspection of raw materials, purchased parts, tools, equipment and gages, and manufactured product.

INTERNAL-COMBUSTION ENGINES

Cylinder Actions. Cylinder Actions in Gas and Gasoline Engines, Dugald Clerk. Jl. Soc. Automotive Engrs., vol. 8, no. 6, June 1921, pp. 523–539, 24 figs. Account of experiments which have been made to develop theory and establish property of flame-working fluid in internal-combustion engines. Description of Clerk plane-pressure starter.

Detonation. Detonation in Internal-Combustion Engines, H. T. Tizard. Eng. & Indus. Management, vol. 5, no. 18, May 5, 1921, pp. 515–518. Conditions under which different types of fuel ignite. (To be continued.)

The Causes of Detonation in Internal-Combustion Engines, H. T. Tizard. North-East Coast Instn. Engrs. & Shipbuilders, advance paper, 21 pp., 16 figs. From Technical considerations and experimental evidence it is concluded that detonation depends not only on ignition temperature but also on maximum flame temperature and effect of temperature on rate of combustion.

Fuels. The Influence of Various Fuels on the Performance of Internal Combustion Engines—V, H. R. Ricardo. Automobile Engr., vol. 11, no. 151, June 1921, pp. 201–205, 9 figs. Tests on variable compression engines. It was found that when both change in specific heat and dissociation are taken into account maximum temperature obtained with economical mixture strengths is substantially the same of all available hydrocarbon fuels, though it is perceptibly lower in case of alcohol; also that gain in efficiency with increase in compression ratio is very considerably greater than is required by air cycle formula.

Temperature-Entropy Diagrams. Temperature Entropy Diagrams for Gas and Oil Engine Cycles, Guy B. Petter. Engineering, vol. 111, no. 2892, June 3, 1921, pp. 669–670, 9 figs. Examples of method of constructing diagram and notes on its interpretation.

[See also AEROPLANE ENGINES; AUTOMOBILE ENGINES, DIESEL ENGINES; GAS ENGINES; OIL ENGINES; SEMI-DIESEL ENGINES.]

IRON

Basic Open-Hearth. Commercially Pure Iron in the Basic Open-Hearth, W. J. Beck. Chem. & Metallurgical Eng., vol. 24, no. 22, June 1, 1921, pp. 965–968, 3 figs. Notes on development of metallurgical process for producing substantially pure ferrite on tonnage basis, without containing excessive amount of gas. Many modifications in rolling mills and galvanizing department were necessary to make finished sheets. Paper read before Am. Iron & Steel Inst.

Pure Iron from Basic Open-Hearth Furnaces, W. J. Beck Iron Age, vol. 107, no. 22, June 2, 1921, pp. 1462–1464, 3 figs. History of developments in production of very low carbon-manganese metal in open-hearth furnaces. Photomicrographs of ingot iron. Paper read before Am. Iron & Steel Inst.

The Development of Commercially Pure Iron in the Basic Open-Hearth Furnace, W. J. Beck. Am. Iron & Steel Inst., advance paper, May 27, 1921, 14 pp., 6 figs.

Electrolytic. "Slip-Lines" and Twinning in Electro-Deposited Iron, W. E. Hughes. Iron & Steel Inst., annual meeting, May 5–6, 1921, advance paper no. 7, 9 pp., 10 figs. Photomicrographs of etched sections of electrolytic iron, deposited under various conditions, are shown. It is suggested that slip lines are produced in grains by forces of contraction that act during formation.

Oxygen Solution. Cupric Etching Effects Produced by Phosphorus and Oxygen in Iron, J. H. Whiteley. Iron & Steel Inst., annual meeting, May 5–6, 1921, advance paper no. 12, 13 pp., 10 figs. Investigations to determine whether cupric reagents would detect small variations of phosphorus content synthetically produced in samples of electrolytic iron, also variations of oxygen content produced in iron samples.

Solid Solution of Oxygen in Iron, J. E. Stead. Iron & Steel Inst., annual meeting, May 5–6, 1921, advance paper no. 10, 5 pp., 6 figs. It is concluded from experiments that when iron is heated in air or oxidizing gases surface layers absorb oxygen which passes into solid solution. When supersaturated oxide falls out of solution, forming separate globules of free oxide which eventually join to form continuous layers.

IRON CASTINGS

Ice Machines. Making Castings for Ice Machines. Foundry, vol. 49, no. 11, June 1, 1921, pp. 419–425, 11 figs. Dense gray castings produced with iron phosphorus. Foundry of York Mfg. Co., York, Pa.

IRON INDUSTRY

Russia. The Russian Coal and Iron Industry, V. Gudkov. Min. & Metallurgy, no. 174, June 1921, pp. 10–13, 2 figs. Location, size and development of iron and coal fields, blast-furnace practice and special features of iron and steel industry.

J

JIGS

Design. Tool Engineering, Albert A. Dowd and Frank W. Curtis. Am. Mach., vol. 54, nos. 21–24, May 26, June 2, 9 and 16, 1921, pp. 905–908, 10 figs., 939–942, 7 figs., 997–999, 7 figs. and 1037–1040, 9 figs. May 26: Design of drill jigs, leaf jigs, clamps, etc. June 2: Typical design of jigs and components; standardization of jig posts and thumb screws. June 9: Bushings. June 16. Drill templets and plate jigs.

L

LABOR

Spain. Labor Unrest in Spain, Anice L. Whitney.

U. S. Dept. of Labor, Monthly Labor Rev., vol. 12, no. 5, May 1921, pp. 154-165. Labor problem presents serious and even menacing possibilities because of revolutionary tendencies of large part of organized labor movement.

LABORATORIES

Aerodynamic. The Adlershof Altitude Testing Plant (Der Aldershofer Höhenprüfstand), K. Fr. Nägele. Zeit. für Flugtechnik u. Motorluftschiffahrt, vol. 12, no. 9. May 17, 1921, pp. 129-132, 5 figs. Consists of vacuum chamber with cradle dynamometer; cooling plant with pumps and re-cooling apparatus; motor-driven blowers; motor installation room with small workshop; refrigerating plant for furnishing of cold air; and room for attendants and instruments.

The Depression Chamber at Friedrichshafen (La chambre a depression de Friedrichschafen), G. Gilles. Aeronautique, no. 23, April 1921, pp. 177-179, 4 figs. Aeronautical laboratory chamber for testing machines in rarefied atmosphere.

Industrial. A Modern Works Laboratory. Eng. Production, vol. 2, no. 33, May 19, 1921, pp. 620-622, 10 figs. Details of new laboratory buildings and equipment erected and installed by the Rudge-Whitworth, Ltd., adjacent to firm's ball-bearing works at Sparkhill, Birmingham. Describes new measuring instruments, including the millimike, measuring sizes within capacity of micrometer to within 0.00001 in.; the pyromike, an optical pyrometer for measuring all temperatures from red heat upwards; and oxyscope, for measuring effects of oxidizing and reducing furnace gases upon various metals.

LATHE TOOLS

Circular Forming Tools. Circular Forming Tools (Rundstähle), Richard Nerrlich. Werkstattstechnik, vol. 15, nos. 8 and 9, Apr. 15 and May 1, 1921, pp. 212-217 and 244-250, 50 figs. Advantages of circular over straight forming tools.

LATHES

Automatic. The Herbert Auto-Lathe. Engr., vol. 131, no. 3413, May 27, 1921, pp. 574-575, 4 figs. Automatic lathe manufactured by Alfred Herbert, Coventry, England.

The Schütte Four Spindle Automatic Lathe (Der Schütte-Vierspindel-Automat). Der praktische Maschinen-Konstrukteur, vol. 54, no. 18, May 5, 1921, pp. 77-80, 7 figs. Machine brought out by Alfred H. Schütte, Cologne-Deutz, in 1915, which is claimed to surpass any known American types, and is especially adapted to quantity production of parts.

Precision Bench Lathes. Tools and Methods for Manufacturing Precision Bench Lathes—II, Machy. (Lond.), vol. 18, no. 451, May 19, 1921, pp. 204-207, 9 figs. Machining and inspection methods used in manufacture of T.L.M. bench lathe.

LIGNITE

Briquetting. Plants. Modern Lignite Briquetting Plants (Einige neuzeitliche Braunkohlen-Brikett-erzeugungsanlagen), B. Schapira. Feuerungstechnik, vol. 9, nos. 13 and 14, Apr. 1 and 15, 1921, pp. 113-117 and 125-129, 19 figs. Briquet factories constructed by the Zeitz Iron Foundry and Machine Constr. Corp., Germany.

LIME

A.S.T.M. Committee Report. Report of Committee C-7 on Lime. Am. Soc. for Testing Matls., paper of annual meeting, June 21-24, 1921, 32 pp., 1 fig. Specifications for finishing hydrated lime. Comparative tests on effect of hydrated lime on concrete mixtures. Specifications for quicklime for structural purposes. Chemical analysis of limestone, lime and hydrated lime.

LOCOMOTIVE BOILERS

Stay Heads. Renewable Stay Heads for Locomotive Fireboxes. Ry. Engr., vol. 42, no. 496, May 1921, pp. 165-168, 8 figs. Stay heads adopted by London & North Western, Ry.

LOCOMOTIVES

British. Recent British Locomotives for Home and Foreign Service. Ry. Engr., vol. 42, no. 496, May 1921, pp. 175-181, 11 figs New three-cylinder express locomotives used by Great Northern & North Eastern Ry.

Coal Economy. Measures of the Austrian Federal Railway for Reducing the Coal Consumption of Steam Locomotives (Massnahmen der oesterreichischen Bundesbahnen zur Verminderung des Kohlenverbrauches der Dampflokomotiven), J. Rihoschek. Zeitung des Vereins Deutscher Eisenbahnverwaltungen, vol. 61, no. 17, Apr. 28, 1921, pp. 322-323. Account of tests carried out by State Railway Administration. (Abstract.)

Consolidation Type. Consolidation Type Locomotives for the Western Maryland Railway. Ry. & Locomotive Eng., vol. 34, no. 6, June 1921, pp. 164-165, 2 figs. Characteristics: Cylinders, 27 in. by 32 in.; boiler diameter, 88 in.; working pressure, 210 lb. per sq. in.; total heating surface, 3498 sq. ft.; superheater, 945 sq. ft.; diameter of driving wheels, 61 in. Table is included showing comparison with others of heavy consolidation type built by Baldwin Locomotive Works.

High-Capacity. Vitalizing Locomotives to Improve Operation, George M. Basford. Ry. Age, vol. 70, no. 21, May 27, 1921, pp. 1227-1231, 5 figs. Increasing capacity of locomotive suggested as means to meet present conditions successfully.

Internal-Combustion. Modern Internal-Combustion Locomotives (Moderne Motorlokomotiven), H. Sorg. Oel- u. Gasmaschine, vol. 18, no. 5, May, 1921, pp. 73-76, 4 figs. Details of locomotives built by Orenstein & Koppel Corp., Montania Department, Nordhausen, Germany.

Mallet. New Mallets and Switchers, Chesapeake & Ohio Ry., Jno. R. Gould. Railroad Herald, vol. 25, no. 6, May 1921, pp. 21-23, 2 figs. Economical advantages of Mallet type of locomotive.

Mine. Compressed-Air Mine Locomotive (Locomotive de mines, à air comprimé), L. Pierre-Guiédon. Génie Civil, vol. 78, no. 15, April 9, 1921, pp. 312-315, 6 figs. Leroux type permitting triple expansion and energy regeneration.

Oil-Burning. Oil Burning Express Locomotives, Highland Railway. Ry. Gaz., vol. 34, no. 19, May 13, 1921, pp. 726-727, 5 figs. Adoptation of Scarab system to engines of 4-6-0 type.

Pressure on Rails. Note on the Determination of the Stresses at the Point of Contact Between the Tire of a Locomotive Wheel and the Head of the Rail, R. Desprets. Bul. Int. Ry. Assn., vol. 3, no. 5, May 1921, pp. 507-511, 2 figs. Formulas for calculating stresses.

LUBRICATING OILS

Air Compressors. Lubricating Oils for Diesel-Engine Air-Compressors. Motorship, vol. 6, no. 6, June 1921, p. 474. Specifications regarding oils suitable for use for lubricating air compressors adopted by Diesel Engine Users Assn.

Viscosity. The Effect of Crystalline Paraffin Wax Upon the Viscosity of Lubricating Oil, E. W. Dean and L. E. Jackson. U. S. Dept. of Interior, Reports of Investigations, Bur. of Mines, serial no. 2249, May 1921, 3 pp. Changes on content of paraffin wax up to maximum of approximately 9 per cent cause negligible variations in viscosity of two Pennsylvania lubricating oil fractions through considerable range of temperature.

LUBRICATION

Marine Turbines. The Lubrication Problem on Shipboard, P. M. Robinson. Mar. Eng., vol. 26, no. 6, June 1921, pp. 458-462, 6 figs. Oiling system recommended by Westinghouse Elec. & Mfg. Co. for geared-turbine equipment.

M

MACHINE SHOPS

Automobile. Special Machines and Fixtures in the Franklin Plant. Machy. (Lond.), vol. 18, no. 451, May 19, 1921, pp. 193-199, 19 figs. Mechanical equipment designed either to increase production, perform special operations, or maintain established standards of accuracy, in different departments of plant in Syracuse.

Design. A Monitor-Type Shop for Building Lathes, Fred H. Colvin. Am. Mach. vol. 54, no. 24, June 16, 1921, pp. 1030-1031, 6 figs. Monitor type of building with slanting sides and all roof drainage towards center of building.

MACHINE TOOLS

Oil-Grooving Machine. The Haigh Oil-Grooving Machine. Machy. (Lond.), vol. 18, no. 452, May 26, 1921, pp. 234-235, 3 figs. Machine recently developed for rapidly cutting external or internal oil grooves in shafts and bearings.

MALLEABLE CASTINGS

Motorcycles. From the Foundry to the Speedway, Herbert R. Simonds. Foundry, vol. 49, no. 12, June 15, 1921, pp. 459-462, 11 figs. Malleable parts used in motorcycles are brazed to steel tubing. Practice of Hendee Mfg. Co. Springfield, Mass.

MALLEABLE IRON

Melting Furnaces. American Malleable Cast Iron—XII, H. A. Schwartz. Iron Trade Rev., vol. 68, no. 24, June 16, 1921, pp. 1662-1668, 5 figs. Types of air furnaces for melting malleable iron.

MANOMETERS

Differential. Report to Committee of Mechanical Arts on Gaging Apparatus of M. Piette (Rapport présenté par M. Ed. Sauvage au nom du Comité des Arts mécaniques, sur les appareils jaugeurs de M. Piette) Ed. Sauvage. Bulletin de la Société d'Encouragement pour l'Industrie nationale, vol. 133, no. 4, April 1921, pp. 321-324, 5 figs. Differential menometers giving indications by magnetism.

MARINE BOILERS

Construction. Marine Boiler Construction. Machy. (Lond.), vol. 18, no. 453, June 2, 1921, pp. 265-271, 13 figs. Methods and machines employed in modern practice.

Design. Standard Conditions for the Design and Construction of Marine Boilers. Steamship, vol. 32, no. 384, June 1921, pp. 296-299. Conditions as to design, workmanship, hydraulic test, etc., Regulations of British Board of Trade. (Concluded.)

Oil-Burning. Oil-Fuel and Mixed-Fuel Burning in Marine Boilers. Shipbuilding & Shipping Rec., vol. 17, no. 23, June 9, 1921, pp 707-708. Methods of burning oil fuel. Practice in British navy. (To be continued.)

Safety Valves. Marine-Boiler Safety Valves, John G. Hub. Mech. World, vol. 69, no. 1795, May 27, 1921, pp. 408, 1 fig. Graphs for determining size of safety valves. Constructed by rule adopted by British Board of Trade, Lloyd's, British Corporation and Bureau Veritas.

Scotch. Quantity Production of Scotch Marine Boilers. Mar. Eng., vol. 26, no. 6, June 1921, pp. 442-445, 4 figs. Practice at works of Federal Shipbuilding Co., Kearny, N. J.

MARINE STEAM TURBINES

Assembling Methods. Turbine Work at the Puget Sound Navy Yard. Am Mach., vol. 54. no. 24, June 16, 1921, pp. 1044-1045, 7 figs. Methods of boring, blading and assembling ship turbines.

METALS

Fatigue. Investigation of Fatigue of Metals Under Stress, H. F. Moore. Min. & Metallurgy, no. 174, June 1921, p. 47. Damage from localized overstresses suggested as explanation of fatigue. (Abstract.)

Hardening. The Slip Interference Theory of the Hardening of Metals, Zay Jeffries and R. S. Archer. Chem. & Metallurgical Eng., vol. 24, no. 24, June 15, 1921, pp. 1057-1067, 11 figs. Mechanical conception of hardening of pure metals, allotropic and non-allotropic, of solid solutions of constant or variable solubility, and of metallic aggregates. In general, hardness is due to interference with slip characteristic property of ductile crystals.

Testing. Report of Committee E-1 on Methods of Testing. Am. Soc. for Testing Matls., paper of annual meeting, June 21-24, 1921, 8 pp. Developments of standard methods of testing metals, especially iron and steel.

Viscosity. The Effect of Temperature on the Modulus of Rigidity and the Viscosity of Solid Metals, Kei Iokibé and Sukéaki Sakai. Tohoku Imperial University, Science Reports, vol. 10, no. 1, Mar. 1921, pp. 1-27, 17 figs. Experiments showed that internal viscosity of different metals increases with rise of temperature except in case of some metals and ferromagnetic substances. Internal viscosity of wire is greatly reduced by annealing.

METEOROLOGY

Aviation Service. Meteorology in the Service of Aviation, G. Dobson. Aeronautical Jl., vol. 25, no. 125, May 1921, pp. 223-229 and (discussion), pp. 230-236. States that meteorology should be of service in two main ways, namely by providing necessary information regarding all weather conditions likely to be encountered on any journey; and by providing statistical information required to settle certain definite questions and explaining physical causes of various phenomena.

METRIC SYSTEM

Arguments Against Adoption in U. S. Danger of Compulsory Metric Standards, H. S. Demarest. Am. Mach., vol. 54, no. 22, June 2, 1921, pp. 949-950. Report of Standardization Committee of Am. Supply & Mach. Manufacturers Assn. at Atlantic City, May 17. (Abstract.)

Arguments for Adoption in U. S. Report of Metric System Committee. Jl. Indus. & Eng. Chemistry, vol. 13, no. 5, May 1921, pp. 401-402. Committee report submitted to Am. Chem. Soc. More extensive and eventually exclusive use of metric system by chemists of U. S. is recommended.

British Decimal System vs. British Trade and the Metric System, E. A. W. Phillips. Concrete Inst., Trans., vol. 9, Apr. 1921, pp. 1-15 and (addenda and discussion) pp. F2-F18. Writer discusses possibility of making the British decimal system (explained in paper) the international standard for trade, commerce and engineering.

Great Britain. The Metric System and World Trade. Nature (Lond.), vol. 107, no. 2692, June 2, 1921, pp. 417-419. Argument in favor of legal adoption of Metric system in Great Britain.

MILLING MACHINES

Cam Milling. The Garvin 12-in Cam Milling Machine. A Suggested Improvement, J. Blakey and Jas. A. H. Shankley. Eng. & Indus. Management, vol. 5, no. 20, May 19, 1921, pp. 566-568, 5 figs. Improvement by employing tumbler gear device which permits milling double-sided cam.

MOLYBDENUM

Norway. Molybdenum Mines in Norway, Eugene Otto Falkenberg. Eng. & Min. Jl., vol. 111, no. 25, June 18, 1921, pp. 1021-1023. Molybdenite deposits occur in considerable quantities in a number of localities, specially in southern part. Mineral is geologically similar to that found elsewhere in the world. Translated from Teknisk Ukeblad.

Properties. Molybdenum, Arthur H. Hunter. Am. Iron & Steel Inst., advance paper, May 27, 1921, 20 pp. Occurences, manufacture, properties and uses.

MOLYBDENUM STEEL

Properties. Manufacture and Properties of Molybdenum Steels, Arthur H Hunter. Iron Age, vol. 107, no. 22, June 2, 1921, pp. 1469 & 1511-1512. Their adaptability to fabrication and their cost Comparison with other alloy steels. Paper read before Am. Iron & Steel. Inst.

Uses. Molybdenum Steel and Its Application, M. H. Schmid. Trans. Am. Soc. for Steel Treating, vol. 1, no. 9, June 1921, pp. 500-505. Also in Chem. & Metallurgical Eng., vol. 24, no. 21, May 25, 1921, pp. 927-929. Beneficial effect of little molybdenum on physical properties of complex alloys, especially allowing safe use of high working temperatures and wide range of quenching and annealing heats. Uses in automotive forgings and pressed metal parts.

Molybdenum Structural Steels and Their Application, Martin H. Schmid. Iron Age, vol. 107, no. 22, June 2, 1921, pp. 1444-1445. Open-hearth practice. Blooming and finish rolling characteristics. Features in thermal manipulations. Paper read before Am. Soc. for Steel Treating.

MOTORSHIPS

Welded. An Electrically Welded Motor Ship. Ship-

building & Shipping Rec., vol. 17, no. 10, May 12, 1921, pp. 581–583, 4 figs. Dimensions: Length, 52 ft. 6 in.; breadth, molded, 13 ft. 1½ in.; depth, molded 6 ft. 10½ in.

N

NICKEL

Black. Black Nickel Solutions, Joseph Haas, Jr. Metal Industry (Lond.), vol. 18, no. 6, Feb. 11, 1921, pp. 106–107. Description of experiments performed, and results obtained in depositing black nickel without use of copper, arsenic or sulpho-cyanate salts.

Electrolytic. Ductile Electrolytic Nickel, Charles P. Madsen. Chem. & Metallurgical Eng., vol. 24, no. 21, May 25, 1921, pp. 922–924. Outline of experimental work on the electrolytes, cathodes and anodes leading to production of electrolytic nickel of greatly improved mechanical properties.

Properties. Nickel. U. S. Dept. of Commerce, Circular of Bur. of Standards, no. 100, Mar. 21, 1921, 106 pp., 26 figs. Properties, statistics of production, and metallurgy.

NICKEL PLATING

Solutions. The Use of Fluorides in Solutions for Nickel Deposition, William Blum. Brass World, vol. 17, no. 5, May 1921, pp. 121–127, 3 figs. Notes on experiments upon the operation of solutions carried out at Bur. of Standards.

NON-FERROUS METALS

A.S.T.M. Committee Report. Report of Committee B-2 on Non-Ferrous Metals and Alloys. Am. Soc. for Testing Matls., paper of annual meeting, June 21–24, 1921. 14 pp. Proposed tentative specifications, methods for chemical analysis, nomenclature and methods of testing.

O

OIL ENGINES

Bolnes. The Bolnes Marine Oil Engine, Arthur R. Brown. Practical Engr., vol. 63, no. 1788, June 2, 1921, pp. 340–341, 1 fig. Two-cycle engines of hot-bulb type.

Kromhout. Kromhout Motor for the Auxiliary Sailing Ship "Neppo." Engineering, vol. 111, no. 2891, May 27, 1921, pp. 646–648, 9 figs. Two-cycle four-cylinder oil engine developing 180 b.hp. at 300 r.p.m.

Vickers-Petters. Two-Stroke Crude-Oil Engine with Electric Starter. Engineering, vol. 111, no. 2891, May 27, 1921, pp. 656–657, 6 figs. Single-cylinder vertical Vickers-Petters engines of hot-bulb type giving working load brake horsepower of 22½ at speed of 375 r.p.m.

OIL FIELDS

Argentina. The Petroliferous Region of Malargué (La region petrolifera de Malargüé), Guillermo Hileman. Ingenieria Internacional, vol. 5, no. 6, June 1921, pp. 348–350, 2 figs. Geological notes on Argentina oil field.

Bolivia. Petroleum in Bolivia, Arthur H. Redfield. Eng. & Min. Jl., vol. 111, no. 23, June 4, 1921, pp. 955. Developments in exploition of oil fields.

Canada. Mackenzie River Oil Fields, E. A. Haggen. Min. & Eng. Rec., vol. 26, nos. 9 & 10, May 1921, pp. 95–116, 10 figs. Geological and topographical notes. Suggestions to prospectors.

Prospects of Oil at Peace River, Edmund M. Spieker. Min. & Eng. Rec., vol. 26, nos. 9 & 10, May 1921, pp. 116–122. Geological description of foothills of Rocky Mountains in British Columbia.

The Mackenzie Oilfield of Northern Canada, T. O. Bosworth. Petroleum World, vol. 18, no. 249, June 1921, pp. 233–241. Possibility of exploitation, Paper read before Instn. Petroleum technologists.

The Possibilities of the Oil Resources of Canada, D. B. Dowling. Trans. Royal Can. Inst., vol. 13, part 1, no. 29, Feb. 1921, pp. 39–47, 2 figs. Geological study.

Morocco. Petroleum at Morocco (Le pétrole au Maroc), Ed. Legé. Génie Civil, vol. 78, no. 16, April 16, 1921, pp. 331–335, 12 figs. Notes on origin and conservation of petroliferous products in northern Morocco.

Oklahoma. The Relation of Mountain Folding to the Oil and Gas Fields of Southern Oklahoma, Raymond C. Moore. Bul. Am. Assn. of Petroleum Geologists, vol. 5, no. 1, Jan.-Feb. 1921, pp. 32–48, 4 figs.

Oregon. Oil Developments in Rogue River Valley, Oregon, A. E. Kellogg. Eng. & Min. Jl., vol. 111, no. 22, May 28, 1921, pp. 913–914.

Pacific Coast. The Petroleum Field of the Pacific Coast, Earle W. Gage. Oil Field Eng., vol. 23, no. 5, May 1921, pp. 2–6, 4 figs. Notes on production and transportation of oil.

Persian-Mesopotamian. The Persian-Mesopotamian Oilfield. Petroleum World, vol. 18, no. 249, June 1921, pp. 225–232, 6 figs. Geological notes.

South America. Petroleum Production in South America with Relation to Recent Petroleum Legislation, J. W. Thompson. U. S. Dept. of Interior, Reports of Investigations, Bur. of Mines, serial no. 2250, May 1921, 6 pp.

Tennessee. Oil Development and Prospects in Tennessee, L. C. Glenn. Bul. Am. Assn. Petroleum Geologists, vol. 5, no. 2, Mar.-April 1921, pp. 168–172.

Texas. The Cretaceous of West Texas and Its Oil Possibilities. Charles Laurence Baker. Bul. Am. Assn. of Petroleum Geologists, vol. 5, no. 1, Jan.-Feb. 1921, pp. 5–28.

The West Columbia Oil Field, Brazoria County, Texas, Donald C. Barton. Bul. Am. Assn. Petroleum Geologists, vol. 5, no. 2, Mar.-April 1921, pp. 212–251, 13 figs.

United States. Our Future Oil Supply, David White. Eng. & Min. Jl., vol. 111, no. 23, June 4 1921, pp. 951–955. Early exhaustion of U .S. oil fields is considered inevitable.

West Virginia. Oil and Gas Development in West Virginia for the Year 1920, David B. Reger. Bul. Am. Assn. of Petroleum Geologists, vol. 5, no. 1, Jan.-Feb. 1921, pp. 80–84.

Wyoming. The Relative Ages of Major and Minor Folding and Oil Accumulation in Wyoming, Max W. Ball. Bul. Am. Assn. of Petroleum Geologists, vol. 5, no. 1, Jan.-Feb. 1921, pp. 49–63, 5 figs.

OIL SHALES

Bibliography. Oil Shale Industry—Selected Bibliography, Victor C. Alderson. Quarterly of Colorado School of Mines, vol. 16, no. 2, April 1921, pp. 27–38.

Distillation. Plant for Hot-Gas Pyrolytic Distillation of Shale, Louis Simpson. Petroleum Times, vol. 5, no. 122, May 7, 1921, pp. 521–523, 4 figs. Description and plan of a 2000-ton-per-day shale oil plant operating an indirect heating process employing hot gases for conveying reacting heat and resultant oil vapors from pyrolysis of the shale.

OIL WELLS

California. Regularity of Decline of Oil Wells in California, R. P. McLaughlin. Bul. Am. Assn. Petroleum Geologists, vol. 5, no. 2, Mar.-April 1921, pp. 178–185, 10 figs.

OPEN-HEARTH FURNACES

Egler. New Open Hearth Furnaces at Brier Hill, George L. Prentiss. Blast Furnace & Steel Plant, vol. 9, no. 6, June 1921, pp. 368–370, 2 figs. Blair Eng. Co's installation under Egler patents. By this process flame is made blow torch rather than Bunsen burner.

Uses Blow Torch Idea in Furnace, George L. Prentiss. Iron Trade Rev., vol. 68, no. 23, June 9, 1921, pp. 1586–1587, 2 figs. Application of blow-torch principle to open-hearth furnaces. Egler patent.

McKune. The McKune System for Open Hearth, P. S. Young. Blast Furnace & Steel Plant, vol. 9, no. 6, June 1921, pp. 371–374, 2 figs. Typical installations.

OXY-ACETYLENE WELDING

Boilers. Process for the Welding of Plants, Especially for Headers of Steam Boilers. (Verfahren zur Verschweissung von Blechen, insbesondere für Wasserkammern von Dampfkesseln). Autogene Metallhearbeitung, vol. 14, no. 8, Apr. 15, 1921, pp. 115–118, 2 figs. Method is developed based on experience and tests of writer.

P

PEAT

Recovery. The Recovery and Fuel Value of Irish Peat. U. S. Dept. of Commerce, Commerce Reports, no. 121, May 25, 1921, pp. 1150–1151. Report of British Dept. of Scientific & Indus. Research. Irish bogs are estimated to cover about 3,000,000 acres.

Utilization. The Use of Peat in Electrical Works (Torf-Elektrizitätswerke), P. Max Grempe. Elektrotechnische Rundschau, vol. 38, no. 6, Mar. 21, 1921, pp. 33–35, 2 figs. Large power plant in Wiesmoor, Germany, in which peat is burned. Details of equipment for production of peat, including excavators, peat-handling machines, and electrical equipment for drive of machines. Conveyance of the peat into power station. Results of experience and tests with burning of peat.

PETROLEUM

Nomenclature. British Petrographic Nomenclature. Min. Mag., vol. 24, no. 5, May 1921, pp. 278–281. Report of joint committee of Geological and Mineralogical Societies on standardization of petrological terms.

Products. Report of Committee D-2 on Petroleum Products and Lubricants. Am. Soc. for Testing Matls., paper of annual meeting June 21–24, 1921, 76 pp., 12 figs. Proposed tentative methods of testing for distillation of gasolene, naphtha, kerosene and similar products, for viscosity of fuel oils, for detection of sulphur and corrosive sulphur compounds in petroleum products in naphthas and illuminating oils, for open-cup flash and fire test and for cloud and pour points of petroleum products.

PIPE, CONCRETE

Hume. Making Concrete Pipes by Centrifugal Force. So. African Jl. of Industries, vol. 4, no. 3, Mar.-April 1921, pp. 224–235, 13 figs. Description of Hume process.

PIPE, STEEL

Centrifugal Casting. New Process for Automatic Making of Steel Tubing. Iron Age, vol. 107, no. 20, May 19, 1921, pp. 1300. Patented process for centrifugal casting of steel pipe. Process comprehends using electric melting of metal in conjunction with centrifugal casting and making of steel tubes, including those of alloy steels, such as are used for manufacturing ball-bearing races.

PIPING

Layouts. Steam Pipe Sizes, Alfred Cotton. Power, vol. 53, no. 21, May 24, 1921, pp. 832–836, 7 figs. Determination by pressure drop instead of velocity. Charts for 0 to 1,000,000 lb. of steam per hr. at pressures up to 300 lb. per sq. in.

PISTONS

Aluminum. Aluminum Piston Competition in Germany (Zum Aluminiumkolbenwettbewerb). Oel-u. Gasmaschine, vol. 18, no. 4, Apr. 1921, pp. 57–58. Interest centered especially in the light pistons of the Griesheim Chemical Works made of so-called electron metal, and in aluminum pistons made by Rudolph Rautenbach, Solingen. Technical notes on qualities of aluminum pistons.

PLANING

Production Systems. Production Planing in Machine Tool Plants. Machy. (N. Y.), vol. 27, no. 10, June 1921, pp. 966–971, 6 figs. Practice at works of G. A. Gray Co. and of Cincinnati Planer Co.

Production Planing in Machine Tool Plants—. Machy. (Lond.), vol. 18, nos. 449 and 452, May 5 and 26, 1921, pp. 129–134, 11 figs. and 225–229, 4 figs. May 5: Practice of shops engaged in manufacture of drilling and boring machines and heavy lathes. May 26: Efficiency factors in production planing; points to observe in obtaining maximum output from planers.

PLATES

Deflection Under Load. The Equilibrium of Rectangular and Elliptic Plates under a Single Load (Ueber das Gleichgewicht von rechteckigen und elliptischen Platten unter einer Einzellast), Hans Happel. Eisenbau, vol. 12, no. 5–6, May 13, 1921, pp. 107–122. Calculations to determine deformation of plates under various conditions.

Stresses in. Researches on Thin Rectangular Plates (Recherches sur les plaques rectangulaires minces), M. Pigeaud. Annales des Ponts et Chaussées, vol. 60, no. 1, Jan.-Feb. 1921, pp. 5–47, 10 figs. Formulas for determining stresses.

PNEUMATIC TOOLS

Electric. Electrically Driven Riveting and Chisel Hammers (Elektrisch betriebener Niet- und Meissel Hammer). Der praktische Maschinen-Konstrukteur, vol. 54, no. 19, May 12, 1921, pp. 78–80, 8 figs. Arrangement consisting of small portable air pump and percussion type tool holder connected by a hose.

Heat Treatment. Heat-Treatment of Thor Toos Parts, J. V. Hunter. Am. Mach., vol. 54, no. 231 June 9, 1921, pp. 991–996, 20 figs. Efficient method, of heat-treating pneumatic tool parts. Contro system to check workmen.

POWER GENERATION

Industries. Industrial Power Loads, D. B. Rushmore and R. F. Emerson. Gen. Elec. Rev., vol. 24, no. 6, June 1921, pp. 475–478, 8 figs. Power demands of manufacturing industries in U. S. and factors which will govern supply of power in future.

PRESSES

Double-Action Drawing. Double-Action Drawing Press. Machy. (Lond.), vol. 18, no. 451, May 19, 1921, pp. 202–203, 2figs. Press designed by Arnold & Large, Ltd., Wolverhampton, in which a compensating action is incorporated, whereby any variation in thickness of plates above or below that for which machine is set is automatically provided for.

PRESSURE VESSELS

Stresses. Calculating Stresses in Pressure Vessels, William C. Strott. Boiler Maker, vol. 21, no. 6, June 1921, pp. 163–166, 4 figs. Strength of materials used in cylindrical tank construction and allowable external pressures on vacuum tanks. (Concluded.)

PROFIT SHARING

British Works. Profit Sharing in Practice. Eng. & Indus. Management, vol. 5, no. 18, May 5, 1921, pp. 513–514. Scheme of profit sharing adopted at works of W. G. Armstrong, Whitworth & Co., Ltd., Rules of employees' deposit fund in operation at these works.

PROPELLERS, SHIP

Standardization. Propeller Wheel Mold Standardization, Enrique Touceda. Foundry, vol. 49, no. 11, June 1, 1921, pp. 431–435, 7 figs. By employing accurately fitting flasks and rigging, propeller wheels true to size and pitch are turned out in about one tenth of usual time. Molding method of George H. Thatcher & Co., Albany, N. Y. Paper read before Am. Inst. Min. & Metallurgical Engrs.

PROTECTIVE COATINGS

Tests. The Protection of Iron with Paint Against Atmospheric Corrosion, J. Newton Friend. Iron & Steel Inst., annual meeting, May 5–6, 1921, advance paper no. 5, pp. 4. Experiments on value of several protective coatings.

PULVERIZED COAL

Combustion. Effect of Preheat and Excess Air on Combustion of Fuel, A. D. Williams. Power, vol. 53, no. 24, June 14, 1921, pp. 960–962, 3 figs. Graphs showing characteristic combustion of pulverized coal.

Developments. Use of Powdered Fuel Under Steam Boilers, Harlow D. Savage. Am. Iron & Steel Inst., advance paper, May 27, 1921, 41 pp., 18 figs. Also in Iron Age, vol. 107, no. 22, June 2, 1921, pp. 1464–1467, 2 figs. Survey of developments in installation of equipment for burning pulverized coal in steam-power plants. Tests and comparative costs. Paper read before Am. Iron & Steel Inst.

Industrial Heating. Industrial Heating with Pul-

verized Coal (Le chauffage au charbon pulvérisé). Revue générale de l'Électricité, vol. 9, no. 22, May 28, 1921, pp. 768–771. Third report of Committee on Economical Utilization of Fuel appointed by French Minister of Public Works. Report deals with survey of developments and requirements for burning pulverized coal efficiently. (To be continued.)

Tests. Present Status of Powdered Coal, Chas. Longenecker. Blast Furnace & Steel Plant, vol. 9, no. 6, June 1921, pp. 394–397, 1 fig. Tests illustrating results obtained in burning various grades of coal.

Uses. Note on the uses of Pulverized Coal (Quelques considerations sur l'emploi du charbon pulvérisé), M. Bulle. Chaleur et Industrie, vol. 2, no. 4, April 1921, pp. 184–188, 2 figs. Design of furnaces for burning pulverized coal.

PUMPING

Costs. Record System of Steam and Motor Pumping Costs, O. A. Anderson. Power, vol. 53, no. 22, May 31, 1921, pp. 887–892. Tables showing quantities of water required for condensers of steam and refrigerating systems and amount of air per gallon of water in air-lift system.

PUMPS

Rotary. A New Principle of Rotary Pump Construction, S. H. Farkas. Chem. & Metallurgical Eng., vol. 24, no. 23, June 8, 1921, pp. 1025–1026. Description of Exeter rotary pump.

PUMPS, CENTRIFUGAL

Efficiency. Centrifugal Pumps—II. Dependency of Efficiency upon Type, Size and Speed, W. D. Canan. Power, vol. 53, no. 20, May 17, 1921, pp. 780–782, 3 figs. Methods of plotting curves.

Operation. Baltimore Pump Sets New Duty Record for Centrifugals. Eng. News-Rec., vol. 86, no. 22, June 2, 1921, pp. 938–939, 3 figs. Tests showed maximum duty of 1,720,250,000 ft-lb. per 1000 lb. of steam at 175 lb. gage pressure, 60 deg. fahr. superheat and water temperature of 70 deg. fahr.

Wilfley. The Wilfley Centrifugal Pump, John Goodman. Practical Engr., vol. 63, no. 1786, May 19, 1921, pp. 311–313, 4 figs. Extracts from report on series of tests carried out on new type of centrifugal pump produced by Wilfley Co., Ltd., London, having impeller fitted with hollow trunnion through which suction water passes on its way to impeller passages.

R

RADIOMETALLOGRAPHY

Research. Roentgen Spectrographic Investigations of Iron and Steel, Arne Westgren. Iron & Steel Inst., annual meeting, May 5–6, 1921 paper no. 11, 23 pp., 4 figs. Research at Physical Instn. of University of Lund, Sweden. Investigations have shown that atoms of iron at ordinary temperature and at 800 to 830 deg. cent. are oriented in exactly the same way, a conclusion which is held to prove that iron does not undergo any allotropic transformation at 768 deg. cent.

RAILS

Acid Bessemer. Bessemer Acid Steel Rails, Cecil J. Allen. Ry. Engr., vol. 42, no. 496, May 1921, pp. 182–184. Records of tests.

Failures. Punishment of Rails, James E. Howard. Iron Age, vol. 107, no. 21, May 26, 1921, pp. 1375–1376, 3 figs. Report to Interstate Commerce Commission on failure of 75-ton Bessemer steel rail. Attention is drawn to difference, both in original and in effect, of rail hardness produced by cold-rolling action of wheels and by their slipping.

Rerolling. Rerolling Rails in New Ohio Mill, John D. Knox. Iron Trade Rev., vol. 68, no. 20, May 19, 1921, pp. 1384–1387, 6 figs. Rerolling mill containing seven stands of 14-in. rolls.

RAILWAY ELECTRIFICATION

India. The Electrification of Indian Railways. Ry. Engr., vol. 42, nos. 496 and 497, May and June 1921, pp. 185–188, and 1 fig., and 218–222, 14 figs. Advantage of using electric locomotives as compared with steam locomotives in heavily graded sections of North Western Ry. of India.

Switzerland. Electrification of St. Gotthard Line, Switzerland, Hans W. Schuler. Ry. Elec. Engr., vol. 12, no. 6, June 1921, pp. 221–227, 15 figs. Electrified section is 101 miles long and has average grade of 2.6 per cent for 30 miles. Single-phase, 15,000-volt power is used.

The Electrification of the Swiss Railways. Engr., vol. 131, no. 3413, May 27, 1921, pp. 563–564. Survey of developments.

RAILWAY MOTOR CARS

Gasoline-Driven. Gasoline-Driven Motor Omnibus for Railroads. Ry. Age, vol. 70, no. 23, June 10, 1921, pp. 1363–1364, 2 figs. Two car units consisting of motor car and trailer for passenger service on branch lines.

RAILWAY OPERATION

Material vs. Personnel Expenses. How Material Costs Affect Railway Income, Harrington Emerson. Ry. Rev., vol. 68, no. 23, June 4, 1921, pp. 851–854, 2 figs. Material vs. personnel expenses considered upon basis of the equated locomotive day.

Selection and Training of Personnel. The Selection and Training of Personnel for Railroad Service (Auslese und Ausbildung des Personals für den unteren Betriebsdienst), Hans Busse. Archiv für Eisenbahnwesen, no. 3, May-June 1921, pp. 564–581, 2 figs. Recommends following measures for increasing efficiency of operation: Selection and correct classification of employees with aid of psychotechnical adaptability test; improvement in instruction methods; regulation of working conditions according to efficiency; suitable arrangement of working and rest quarters; wide use of technical expedients for facilitating work.

Train Dispatching. New Record Demonstration of Heavy Tonnage Train Handling. Ry. & Locomotive Eng., vol. 34, no. 6, June 1921, pp. 151–155, 7 figs. Experience of Virginian railway in handling trains of 16,000 gross tons on heavy grades in regular train service.

Train Loading. Record Train Loading Features Virginian Operation. Ry. Age, vol. 70, no. 21, May 27, 1921, pp. 1203–1208, 7 figs. Methods used to handle loads of 8000 to 9000 tons in regular course.

RAILWAY REPAIR SHOPS

Welding. Shop Notes from Buffalo. Elec. Ry. Jl., vol. 57, no. 25, June 18, 1921, pp. 1114–1118, 14 figs. Reclamation of material and welding methods at railway repair shop of Int. Ry., Buffalo.

RAILWAY SHOPS

Mechanical Equipment. Revivifying the Railroad Shop, G. W. Armstrong. Ry. Mech. Engr., vol. 95, no. 6, June 1921, pp. 341–345, 8 figs. Notes on installation of mechanical equipment.

RAILWAY SIGNALING

England. Three-Position Signaling in Great Britain Ry. Signal Engr., vol. 14, no. 6, June 1921, pp. 211–216, 10 figs. First installation of this type in England made on Great Western. A. C. apparatus fog repeators and automatic stops used.

RAILWAYS

Narrow-Gage. Development of Narrow-Gage Railways in Prussia (Entwicklung der Kleinbahnen in Preussen). Archiv für Eisenbahnwesen, no. 3, May-June 1921, pp. 607–637. Statistical data.

Short Line Roads. The Transportation Problem and the Short Line Roads. Ry. Rev., vol. 68, no. 23, June 4, 1921, pp. 860–862. Extracts from report of president of American Short Line Railroad Assn.

REAMERS

Manufacture. Solid Reamers for Precision Holes (Feste Reibahlen fur Genaulöcher), Jos. Reindl. Betrieb, vol. 3, no. 16, May 10, 1921, pp. 461–467, 21 figs. As excess of reamer diameter for limit-gage holes, ⅔ to ¾ of the tolerance above lower measurement of hole is accepted as permissible. Writer recommends that hand reamers be tapered at end for a length equal to ¼ the length of flute. Notes on grinding of hand and machine reamers.

Standards. Report of the German Industries Committee on Standards (Mitteilungen des Normenausschusses der Deutschen Industrie), Betrieb, vol. 3, no. 16, May 10, 1921, pp. 227–239, 19 figs. Proposals of Board of Directors for hand and machine reamers (solid adjustable and shell), and pilot shanks.

REDUCTION GEARS

Design. Mechanical Reduction Gears on Warships and Merchant Ships, John H. Macalpine. Engineering, vol. 111, nos. 2890 and 2891, May 20 and 27, 1921, pp. 609–611, and 640–642, 2 figs. Graphs indicating tooth pressure per inch of face. Arguments against introducing flywheel just aft of gear.

REFRACTORIES

Oil-Fired Furnaces. Refractories for Oil-Fired Furnaces and Boilers, W. H. Grant. Jl. Am. Ceramic Soc., vol. 4, no. 5, May 1921, pp. 390–392. Causes of failure of firebrick in oil-fired furnaces.

Tests. Resistance Tests on Refractory Products under Load at Different Temperatures, V. Bodin. Colliery Guardian, vol. 121, no 3151, May 20, 1921, pp. 1454–1455, 3 figs. Account of experiments and table showing resistance figures for various substances tested. (Abstract.) Paper read before Ceramic Soc., Refractory Materials Sect., Paris. See also Iron & Steel Trades Rev., vol. 102, no. 2777, May 20, 1921, pp. 694–695, 1 fig.

REFRIGERATING PLANTS

Steam Engines. Steam Engines for Refrigerating Plants, W. H. Motz. Power, vol. 53, no. 23, June 7, 1921, pp. 916–919, 6 figs. Selection and efficient operation of steam engines for driving ice-making and refrigeration plants. Graphs showing comparative performances of various steam engines.

Wall Insulation. Insulation of Concrete Walls Nolan D. Mitchell. Concrete Age, vol. 34, no. 2, May 1921, pp. 15–17. Tables giving heat conductivity of common wall materials.

Welded Ammonia Containers. Some Tests on Welded Ammonia Containers, E. A. Fessenden. A.S.R.E. Jl., vol. 7, no. 4, Jan. 1921, pp. 281–305, 31 figs. Results of tests made to compare different methods of constructing cylinders for handling anhydrous ammonia in refrigerating plant practice.

RESEARCH

British Association. The British Research Association for the Woolen and Worsted Industries, James P. Hinchliffe. Jl. Royal Soc. of Arts, vol. 69, no. 3575, May 27, 1921, pp. 439–453. Constitution and activities.

Industrial. Governmental Research, George K. Burgess. Trans. Royal Can. Instn., vol. 13, part 1, no. 29, Feb. 1921, pp. 121–132. Discusses organization of industrial research under auspices of government.

Scientific, United States. Funds Available in 1920 in the United States of America for the Encouragement of Scientific Research, Callie Hull. Bul. Nat. Research Council, vol. 2, no. 9, part 1, Mar. 1921, 81 pp.

University of Illinois. The Functions of the Engineering Experiment Station of the University of Illinois, Charles Russ Richards. University of Ill. Bul., vol. 18, no. 24, Feb. 14, 1921, 21 pp.

ROAD CONSTRUCTION

Machinery. Road Building and the Mechanical Engineer, B. H. Piepmeier, R. C. Marshall, Jr. and C. D. Curtis. Mech. Engr., vol. 43, no. 6, June 1921, pp. 386–390, 5 figs. Problems in relation to road-building machinery presented under auspices of Materials Handling Division at Am. Soc. Mech. Engrs. spring meeting. Titles of papers were: Road-Construction Plants; Mechanical Needs in Highway-Construction Machinery; and Planning and Organizing a Road Job for Mechanical Handling of Material.

ROADS, CONCRETE

Reinforced. New Design for Illinois Concrete Highways. Eng. World, vol. 18, no. 6, June 1921, pp. 421–422, 3 figs. Corrugated longitudinal center joint. Bars tie adjacent sections and resist shear.

ROCK DRILLS

Magnetic Analysis. Application of Magnetic Analysis to Rock Drills, Charles W. Burrows. Min. & Metallurgy, no. 174, June 1921, pp. 42–43, 1 fig. Experience in use of magnetic defectoscope. (Abstract.)

Steel. What is the Ideal Drill Steel? Frank H. Kingdon. Min. & Metallurgy, no. 174, June 1921, pp. 47 and 50–51, 1 fig. Answers to questionnaire showed that double-arc, double-taper bit and cross-bit give best service.

Tests. Analysis of Some Drill-Steel Tests, Francis B. Foley. Min. & Metallurgy, no. 174, June 1921. pp. 43 and 46–47, 1 fig. Tests on breakage of shank and bit end. Breakage is attributed to faulty practice in forging and hardening. (Abstract)

ROLLING MILLS

Cost of Rolling Steel. Review of Cost of Rolling Steel in Various Mills, G. E. Stoltz. Assn. Iron & Steel Elec. Engrs., vol. 3, no. 5, May 1921, pp. 99–115 and (discussion) pp. 116–154, 2 figs. 1 on supp. plate. Outlines method of reducing cost of producing steel. Includes tables of power and main drive operating cost of rolling steel, and chart showing comparison of cost of rolling steel on electric and steam-driven reversing blooming mills.

Sheet Mills. Operates Sheet Mill in Indiana, E. F. Ross. Iron Trade Rev., vol. 68, no. 24, June 16, 1921, pp. 1651–1656, 8 figs. Mill galvanizing plant and fabricating shop designed with a view to simplifying handling of materials.

ROPE DRIVE

Belting vs. Manila Rope and the Engineer, Rupert E. Shotts and Harry E. Wade. Eng. World, vol. 18, no. 6, June 1921, pp. 405–409, 4 figs. Graph giving relative cost per foot of drive for rope and belting, using most efficient speeds in each case.

Wire Rope. Power Transmission by Wire Rope, L. J. Dixon. Power, vol. 53, no. 22, May 31, 1921, pp. 893–896, 8 figs. Application and arrangement of system, type and size of sheaves. Rope construction, driving tension, velocities and horsepower transmitted. Idle sheaves and takeup devices.

S

SCALES

Track. 200-Ton Railway Track Scale, Canadian Pacific Railway, H. S. Bare. Can. Ry. & Mar. World, no. 279, June 1921, pp. 289–290, 7 figs. Tapered floor deck is notable feature.

SCIENTIFIC INSTRUMENTS

Design. The Design and Construction of Scientific Instruments, Robert S. Whipple. Engineering, vol. 111, no. 2891, May 27, 1921, pp. 659–662, 12 figs. Presidential address at meeting of British Optical Soc.

SCIENTIFIC MANAGEMENT

See INDUSTRIAL MANAGEMENT.

SCREW THREADS

Standardization. Committee for Standardization of Screw Threads (Commission pour l'unification des filetages). Bulletin de la Société d'Encouragement pour l'Industrie nationale, vol. 133, no. 4, April 1921, pp. 380–383, 1 fig. Table giving standard dimensions of bolts and screws of from 2.5 mm. to 12 mm. diameter. Adopted by Committee of Union of Electrical Syndicates in France.

SEMI-DIESEL ENGINES

Vegetable Oils as Fuel. Vegetable Oils as Fuel for Semi-Diesel Engines, Eugenio Normand. Shipbuilding & Shipping Rec., vol. 17, no. 21, May 26, 1921, pp. 649–650, 2 figs. Experiments carried out by Ansaldo San Giorgio Works on 20 b.hp. semi-Diesel engines.

SHAFTS

Keyways. Influence of Circular Holes and Keyways on the Strength of Shafts (Einfluss von Löchern und Nuten auf die Beanspruchung von Wellen), L. Föppl. Zeit. des Vereines deutscher Ingenieure, vol. 65, no. 19, May 7, 1921, pp. 497–498, 2 figs. Increase

of stress in shafts due to perforations is said to be the same as in a similarly perforated plate. Increase in danger of rupture due to holes and keyways is twice and three times as great.

SHIP PROPULSION

Hernu Propulsion Turbine. Mechanical Propulsion of Ships (Les bateaux a propulsion mécanique), M. Monfier. Nature (Paris), no. 2458, May 14, 1921, pp. 308–310, 2 figs. Description of Hernu propulsion turbine.

Jet Propulsion. The Effective Propulsion of Craft for use on Shallow and Obstructed Waterways, J. H. Gill. Trans. Inst. Mar. Engrs., session 1921–22, vol. 33, Apr. 1921, pp. 57–74, 14 figs. Discussion of jet propulsion.

SHIP PROPULSION, ELECTRIC

U. S. S. Tennessee. Electric Drive and the U. S. S. Tennessee, H. M. Southgate. Elec. Jl., vol. 18, no. 6, June 1921, pp. 239–289, 70 figs. Series of articles describing propelling machinery of U. S. S. Tennessee. Titles are: Motion—$30,000,000 Worth R. A. Bachmann; General Arrangement of Propelling Machinery for the U. S. S. Tennessee, W. E. Thau; The Propelling Motors of the U. S. S. Tennessee, H. L. Barnholdt; The Control Room Circuit Breaker Equipment of the U. S. S. Tennessee, E. K. Read; The Control Equipment for the Propelling Machinery of the U. S. S. Tennessee, M. Cornelius; The Lighting Sets on the U. S. S. Tennessee, J. A. MacMurchy and A. O. Loomis; The Condensing Equipment and Oil Cooling System for the U. S. S. Tennessee, J. H. Smith and A. O. Loomis; The Control of the Secondaries of the Main Propulsion Motors of the U. S. S. Tennessee, W. C. Goodwin; The Stability Indicator, R. T. Pierce; The Main Turbines and Turbine Speed Control for the U. S. S. Tennessee, W. B. Flanders; The Main Generators of the U. S. S. Tennessee, R. E. Gilman and Installation and Maintenance of Automatic Substations, C. A. Butcher.

SOOT BLOWERS

Tests. Some Results with Mechanical Soot Blowers, Robert June. Power House, vol. 14, no. 7, April 5, 1921, pp. 21–24. Survey of recent tests with coal, pulverized fuel and oil.

SPRINGS

Formulas for Design. Formulas for Spring Design. Machy. (Lond.), vol. 18, no. 451, May 16, 1921, pp. 209–211, 4 figs. Formulas used by draftsmen and designers of Briggs Stratton Co., Milwaukee.

SPROCKET CHAINS

Standardization. Proposed Standard Roller-Chain Sprocket. Am. Mach., vol. 54, no. 24, June 16, 1921, pp. 1052–1053, 2 figs. Excerpt from report of Chain Division of Standards Committee of Soc. of automotive Engrs. at West Baden, Ind., May 24, 1921.

SPRUCE

Moduli of Rigidity. The Moduli of Rigidity for Spruce, H. Carrington. Lond., Edinburgh & Dublin Philosophical Mag. & Jl. of Sci., vol. 41, no. 246, June 1921, pp. 848–860, 6 figs. partly on supp. plate. Investigations conducted in College of Technology, Manchester, for British Air Board and Royal Aircraft Establishment.

STACKS

Corrosion. Surrounding Corroded Steel Stacks with Concrete, John V. Schaefer. Power Plant Eng., vol. 25, no. 11, June 1, 1921, pp. 560–561, 2 figs. Experience at South Works, Illinois Steel Co., South Chicago.

STAMPING

Methods. Producing a Stamped Shift Lever Dome, N. T. Thurston. Iron Age, vol. 107, no. 22, June 2, 1921, pp. 1441–1444, 11 figs. Dies and method of production.

STANDARDIZATION

Australia. An Engineering Standards Association for Australia. Sci. & Industry, vol. 2, no. 1, Jan. 1921, pp. 43–44. Scheme of organization for Australian Standards Association. Proposal has been approved by committee appointed by Council of Instn. of Engrs., Australia.

STEAM

Entropy. Entropy of Steam, M. J. Eichhorn. Power vol. 53, no. 24, June 14, 1921, pp. 966–967, 1 fig. Nomogram for entropy of steam.

High-Pressure. The Properties of High-Pressure Steam, M. J. Eichhorn. Power, vol. 53, no. 20, May 17, 1921, pp. 782–783, 1 fig. Nomogram for properties of steam up to critical point.

Properties. Properties of Steam (Ueber einige Eigenschaften des Wasserdampfes), Max Jacob Zeit. des Vereines deutscher Ingenieure, vol. 65, no. 22, May 28, 1921, pp. 568–570. Criticisms of German technical—thermodynamical research made by English journal, Engineering, are refuted. In particular, it is shown that the well-known and established equations of state of steam, including the simple equation of Callendar, in the neighborhood of saturation at high pressures, lead to values of specific heat which are contradictory to the experimental results. On the other hand, the specific volume can be obtained from the experimental values of the specific heat, graphically or as shown by Eichelberg, in form of a broadly applicable equation of state.

Superheated. See SUPERHEATED STEAM.

Total Heat. Total Heat of Steam, M. J. Eichhorn. Power, vol. 53, no. 23, June 7, 1921, pp. 936–937, 1 fig. Nomogram for total heat of steam, computed from heat formulas.

STEAM ENGINES

High-Power. High-Power Engines and Heat Utilization (Grosskraftmaschinentechnik und Wärmeausnutzung), H. Schömburg. Wirtschaftsmotor, no. 3, Mar. 1921, pp. 17–19, 9 figs. Describes several such machines which are among the largest of their kind, including two blast-furnace blowing engines by Ehrhardt & Sehmer, Saarbrücken; the largest steam engine built by same firm and various types of turbocompressors.

Uniflow. Uniflow Steam Engines with High-Lift Conoidal Disk Valve and Layshaft of Double Speed (Gleichstromdampfmaschine mit Hochhub-Düsentellerventil und Steurwelle doppelter Drehzahl), J. Stumpf. Zeit des Vereines deutscher Ingenieure, vol. 65, no. 19, May 7, 1921, pp. 492–494, 7 figs. Discusses diminishing the clearances and surfaces of uniflow engines by employing high-lift conoidal disk inlet valves driven by layshaft whose speed is double that of engine. Abstracted from author's book, "Die Gleichstromdampfmaschine," R. Oldenbourg, Münich.

[See also REFRIGERATING PLANTS. Steam Engines.]

STEAM-ELECTRIC PLANTS

Chemical Works. New Power Plant of Monsanto Chemical Works. Power, vol. 53, no. 20, May 17, 1921, pp. 768–773, 7 figs. Power plant in which compound steam engines generate direct current for electrolytic work and discharge their exhaust to mixed-pressure turbo-generators which furnish alternating current for lighting and power.

Chicago Calumet Station. Calumet Station Equipment and Operating Features. Elec. Rev. (Chicago), vol. 78, no. 22, May 28, 1921, pp. 849–851 and 870–871, 3 figs. Details of coal-handling and burning apparatus, generating units, and switching equipment.

Developments. Practices and Tendencies in Steam Generating Plants. Elec. World, vol. 77, no. 23, June 4, 1921, pp. 1311–1314, 4 figs. Tendency is to increase turbine speeds and to improve turbine economy by raising steam pressure. Committee report submitted at conference of Nat. Elec. Light Assn.

Dodge Bros. Dodge Brothers' New Power Plant. Iron Age, vol. 107, no. 21, May 26, 1921, pp. 1391–1394, 6 figs. Steam-electric plant built on unit plan, each unit consisting of two boilers and with generating capacity of 10,000 kw.

Dodge Brothers Modern Power Plant, Thomas Wilson. Power, vol. 53, no. 21, May 24, 1921, pp. 841–849, 14 figs. Plant is arranged on unit plan and is to have ultimate capacity of 50,000 kva. Combined natural—and induced-draft cooling tower is mounted 33 ft. above grade over loading platform. To maintain heat balance house turbine is to operate in conjection with synchronous-motor-generator set.

Glasgow. The Dalmarnock Power Station. Engineering, vol. 111, nos. 2891 and 2893, May 27 and June 10, 1921, pp. 635–639 and 650, 38 figs. partly on 4 supp. plates, and 703–707, 21 figs. Glasgow steam-electric plant designed for ultimate capacity of 200,000 kw. Details of 16,000-kw. three-phase generators.

Heat Balance. Heat-Balance Study of Colfax Power Station, W. P. Gavit. Power, vol. 53, no. 21, May 24, 1921, pp. 824–827, 4 figs. Thermal efficiency of Colfax station is 18.46 as compared with 20.2 for ideal station.

Pennsylvania. The Generating Systems of the West Penn Power Company, G. G. Bell. Elec. Jl., vol. 18, no. 5, May 1921, pp. 175–193, 18 figs. Steam-electric plants with capacities of 60,000 kw., 30,000 kw., and 25,000 kw.

Philadelphia. Delaware Power Station—The Philadelphia Electric Company. Power, vol. 53, no. 21, May 24, 1921, pp. 806–817, 14 figs. Steam-electric plant designed for capacity of 180,000 kw. in six 30,000-kw. units, of which two have been installed. Single cylinder turbo-generating units operating at 1800 r. p. m. are used.

Pittsburgh. The Power Stations of the Duquesne Light Company, J. M. Graves. Elec. Jl., vol. 18, no. 5, May 1921, pp. 193–210, 20 figs. Colfax station in Pittsburgh district with present capacity of 60,000 kw.

Toledo. The Acme Power Company Plant, Cyril E. Lewis. Elec. Traction, vol. 17, no. 5, May 1921, pp. 301–305, 4 figs. Power plant at Toledo, Ohio, designed for ultimate capacity of 200,000 kw., including modern generating machinery and coal-handling facilities.

STEAM POWER PLANTS

Central Heating Stations. Modern Tendencies in the Construction of Central Plants (Les tendances modernes dans la construction des centrales), F. Scoumanne. Revue universelle des Mines, vol. 9, no. 3, May 1, 1921, pp. 229–241, 2 figs. Central heating stations. (To be continued.)

Operation. Efficient Operation of Oil Burning Steam Plants, C. H. Delany. Power Plant Eng., vol. 25, no. 11, June 1, 1921, pp. 551–556, 7 figs. Method of establishing standards of efficiency at various loads. Paper read before San Francisco Section, Am. Soc. Mech. Engrs.

Power for Toasting Cornflakes. Power Plant Eng., vol. 25, no. 11, June 1, 1921, pp. 545–550, 11 figs. Details of equipment and operation of steam power plant.

STEAM TURBINES

Developments. Recent Improvements in Steam Turbine Design. Engr., vol. 131, nos. 3410, 3412 and 3413, May 6, 20 and 27, 1921, pp. 482–484, 5 figs., 534–536, 10 figs., and 562–563, 6 figs. May 6: Marine-type geared turbo-generator manufactured by W. H. Allen, Sons & Co., Bedford, England. May 20: Types recently manufactured by Brown, Boveri & Co., May 27: Types built by English Electric Co.

Shaft Glands. Steam-Turbines Shaft Glands, John R. Baker. Power, vol. 53, no. 22, May 31, 1921, pp. 881–883, 6 figs. Methods of packing.

Thyssen-Röder Limit. The Thyssen-Röder Steam Turbineas a Limit Turbine, Karl Röder. Eng. Progress, vol. 2, no. 4, Apr. 1921, pp. 81–82, 3 figs. Reaction drum is fitted with disks without central bore, thus permitting control of volume of hore-pressure steam with small losses due to exhausting.

STEEL

A. S. T. M. Committee Report. Report of Committee A-1 on Steel. Am. Soc. for Testing Matls., paper of annual meeting, June 21–24, 1921, 42 pp., 1 fig. Proposed revisions in standards and tentative standards for steel, welded and seamless steel pipe, carbon steel, rails, cold-drawn steel wire for concrete reinforcement, and boiler tubes.

Alloy. See ALLOY STEELS.

Basic. Deoxidation Phenomena in the Basic Process (Desoxydationsvorgänge im Thomasverfahren), O. von Keil. Stahl u. Eisen, vol. 41, no. 18, May 5, 1921, pp. 605–611, 3 figs. Results of tests carried out in nine large basic steel works presented in tables and charts.

Drill. Drill Steel from Hollow Ingots, P. A. E. Armstrong. Chem. & Metallurgical Eng., vol. 24, no. 22, June 1, 1921, pp. 960–964, 9 figs. Definite effort to produce hollow drill steel with decarbonized interior surface by inserting mild-steel tube in ingot mold, plugging it with sand, casting steel and subsequently rolling to size. Paper read before Am. Min. & Metallurgical Engrs.

Impact Testing. Impact Testing of Notched Bars (Essais de choc sur barreaux entaillés), M. Legrand. Revue de Métallurgie, vol. 18, no. 4, April 1921, pp. 225–228, 1 fig. Tests conducted by French Permanent Commission. Bars tested were of Martin steel.

New Impact Tests Conducted by the French Standardization Commission (Quelques essais de choc sur nouvelles éprouvettes de la commission de standardisation), M. Léon Guillet. Revue de Métallurgie, vol. 18, no. 4, April 1921, pp. 221–224. Tests on steel bars subjected to different heat treatments.

Internal-Combustion Engine Valves. Steels for Internal-Combustion Motor Valve, G. Gabriel. Automotive Manufacturer, vol. 42, no. 2, May, 1921, pp. 19–22. Minimum requirements as determined in use of light-weight and airplane engines. Effect of high temperatures on various steel. Metallurgical viewpoints Translated from La Technique Automobile et Aerienne. (To be continued.)

Marine Engineering. Steel from the Standpoint of Marine Engineering, W. H. Hatfield. Jl. West of Scotland Iron & Steel Inst., vol. 28, part 5, session 1920–1921, Feb. 1921, pp. 52–72 and (discussion) pp. 72–78, 17 figs. on 2 supp. plates. Writer concludes that (1) it is desirable to use, wherever possible, ship plates and sections of increased mechanical strength; (2) it is advisable to extend use of some special steels now available for power unit and transmission parts; and (3) it is desirable to increase use of other special steels available for resisting rust and where needed, high temperatures.

Mechanical Properties. Calculation of Mechanical Properties of Steel from its Chemical Composition, Hugh O'Neill. Iron & Coal Trades Rev. vol. 102, no. 2777, May 20, 1921, pp. 700. Formula is developed.

Metallography. Report of Committee E-4 on Metallography. Am. Soc. for Testing Matls., paper of annual meeting, June 21–24, 1921, 16 pp. Proposed tentative methods of metallographic testing on iron and steel.

Molybdenum. See MOLYBDENUM STEEL.

Quenching Cracks. On the Cause of Quenching Cracks, Kôtarô Honda, Tokujirô Matsushita and Sakaé Idei. Iron & Steel Inst., annual meeting, May 5–6, 1921, advance paper no. 6, 16 pp., 9 figs. It is concluded from tests that in quenched steel certain amount of austenite is generally present intermingled in martensite. Amount of austenite increases as quenching temperature increases. Quenching cracks occur when hardness in central portion is much greater than in periphery.

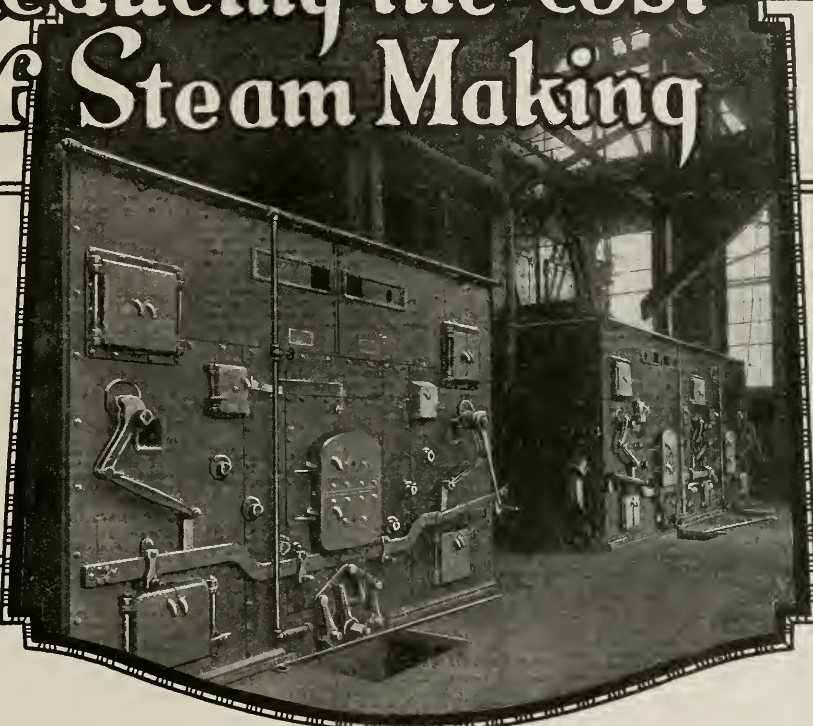
Specifications. French Specifications for Carbon Steels. Iron Age, vol. 107, no. 21, May 26, 1921, pp. 1372–1374. Full details for bars, blooms, billets and slabs of other than tool steels. Static, structure and shock, as well as welding tests, required.

Stainless. Stainless Steel, Its Composition and Properties, Elwood Haynes. Iron Age, vol. 107, no. 22, 107, no. 22, June 2, 1921, pp. 1467–1469. Manufacture and uses. Influence of temperature. Limits of chromium content. Paper read before Am. Iron & Steel Inst.

Sulphur Determination. Comparison of Different Methods of Estimating Sulphur in Steel, T. E. Rooney. Iron & Steel Inst., annual meeting, May 5–6, 1921, advance paper no. 9, 13 pp. Experiments made with carbon and nickel-chromium steels.

Tests. Comparative Tests of Steels at High Temperatures, R. S. MacPherran. Am. Soc. for Testing Matls., paper of annual meeting, June 21–24 1921, 9 pp., 6 figs. Tests made to determine comparative properties of various steels at high temperatures under operating conditions at temperature between 600 to 1000 deg. fahr.

Reducing the Cost of Steam Making



Back in 1907 the New York Air Brake Co. became interested in the possibilities of savings to be made by using

MURPHY AUTOMATIC FURNACES

in place of hand firing methods. A test made on a 150 h. p. boiler, hand fired, showed a cost of 20.39 cents per 1000 lbs. water evaporated. A Murphy was then put in under this same boiler reducing the cost to 14.49 cents per 1000 lbs. of water evaporated.

This *demonstrated saving* together with smokeless operation and low maintenance has led to *three repeat orders* received from this company.

At that time coal cost $2.95 a ton at their plant—*today that won't cover the freight per ton to most plants.*

Think how much more the Murphy can save at to-day's coal prices!

Find out what a Murphy can do for you in your plant. *Send for Catalog*

STEEL CASTINGS

Centrifugal. Testing Centrifugally Cast Steel, George K. Burgess. Iron Trade Rev., vol. 68, no. 21, May 26, 1921, pp. 1443–1447, 15 figs. Examination of several cylinders of various wall thickness and composition showed little segregation of elements and few blow holes. Physical properties of specimens were improved materially by heat treatment.

Manufacture. Checking Troubles in Steel Castings, R. B. Farquhar, Jr. Foundry, vol. 49, no. 12, June 15, 1921, pp. 475–483, 23 figs. Notes on proper pouring, gating and feeding. Paper read before Am. Foundrymen's Assn.

STEEL FOUNDRIES

Electric-Furnace. Steel Foundry Rearranged and Enlarged, Gilbert L. Lacher. Iron Age, vol. 107, no 22, June 2, 1921, pp. 1470–1474, 9 figs. Replacement of cupolas and converters by electric furnace at plant of Chicago Steel Foundry Co.

STEEL, HEAT TREATMENT OF

Drill Steel. Heat Treatment of Rock-Drill Steel, George H. Gilman. Min. & Metallurgy, no. 174, June 1921, pp. 35 and 38–39 and 42, 1 fig. Suggestions in regard to heat-treating practice. (Abstract.)

Methods. Carburizing, Hardening and Tempering High Carbon Alloy Steels in 130 Minutes, R. L. Gilman. Trans. Am. Soc. for Steel Treating, vol. 1, no. 8, May 1921, pp. 445–448. Method is suggested.

Tool Steel. The Prevention of Hardening Crack and the Effect of Controlling Recalescence in a Tungsten Tool Steel, Shipley N. Brayshaw. Iron & Steel Inst., annual meeting, May 5–6, 1921, advance paper no. 1, 86 pp., 26 figs. Research carried out on tool steel containing about 1.1 per cent of carbon and 0.8 to 0.9 per cent of tungsten. Changes that occur during halts in heating and cooling were investigated in number of bars which, after soaking for various periods of time at temperatures near critical points, were quenched in water. Results suggested that, both in heating and in cooling, changes Acl. 2.3 and Ar 3.2.1. take place in stages which may be separated one from another if sufficient time is allowed for process.

STEEL, HIGH-SPEED

Hardness. Relation of the High Temperature Treatment of High Speed Steel to Secondary Hardening and Red Hardness, Howard Scott, Trans. Am. Soc. for Steel Treating, vol. 1, no. 9, June 1921, pp. 511–526, 18 figs. Based on study of microstructure, hardness, density, magnetic properties and thermal characteristics of a typical high speed steel.

STEEL MANUFACTURE

Direct Processes. Making Steel Direct from Ore. Iron Trade Rev., vol. 68, no. 20, May 19, 1921, pp. 1375–1376. Comparison of Basset and Jones processes. Basset process maintains higher temperature in furnace by introducing preheated air and carbon and chemical reactions differ to some extent.

New Method of Manufacturing Cast Iron and Steel in France, Paul H. Cram. U. S. Dept. of Commerce, Commerce Reports, no. 130, June 6, 1921, pp. 1330. It is stated that Basset Steel Works, after having concluded successful experiments in 100-ton furnace, will construct 12 Basset furnaces for direct manufacture of steel having total daily capacity of 3000 tons.

Steel Direct from Ore by Moffat Process, W. F. Sutherland. Iron Age, vol. 107, no. 22, June 2, 1921, pp. 1450–1452, 3 figs. Reduction in metallizer and conversion into steel in electric furnaces.

The Canadian Steel Industry and the Direct Process, Noel Statham. Iron & Steel of Canada, vol. 4, no. 4, May 1921, pp. 91–98, 3 figs. Bourcoud open-cycle direct process and its economical possibilities under present conditions of Canadian iron and steel industrial development. Process consists in reducing iron ore with gases at sufficiently high temperature, transferring reduced metal to electric furnace where it is melted, and subsequently to another electric furnace where it is finally refined.

Electric-Furnace. Electric Furnaces for Making Steel—IV, Alfred Stansfield. Blast Furnace & Steel Plant, vol. 9, no. 6, June 1921, pp. 381–385, 6 figs. General features and advantages of Ludlum furnace and of Vom Baur furnace. Classification of electric steel-making furnaces.

Power-Plant Evolution

A Discussion of the Decrease Brought About in the Cost of Producing Electric Power, and of the Possibilities of Further Increasing Plant Efficiencies by the Use of Higher Steam Pressures, Air Preheating, Improved Methods of Feedwater Heating, Etc.

By C. F. Hirshfeld,[1] Detroit, Mich.

Few people who are not directly interested realize the tremendous extent to which both modern industrial life and modern family life are dependent on electric energy, or electric power as it is more commonly called. The revolutionary changes in industrial methods which followed the introduction of the water wheel and steam engine have been treated extensively in literature, and almost every one who reads and thinks knows that the entire social structure of today rests, ultimately, on these prime movers. The part played by electric power, however, has not been so widely advertised and is not so well appreciated.

It is practically impossible to obtain accurate and complete data of the electrical power output of the country but it may be stated that the per capita consumption of central-station power has increased from 23 kw-hr. in 1900 to 435 kw-hr. in 1920. These figures represent the growth over a fairly short period and are indicative of the rate at which electrical power has come into use in the country as a whole. As a matter of fact, however, they do not tell the whole story, because much of the electric power used by street railways is not included and because the total population of the country has been used as the divisor. Since the greatest use of power is in the large and small industrial centers, division by the total population of the country gives too small a figure.

To indicate the significance of this feature Fig. 1 is presented. This figure refers to the city of Detroit, which has had a most remarkable growth, and it is therefore not properly representative of all industrial centers, indicating a somewhat extreme case.

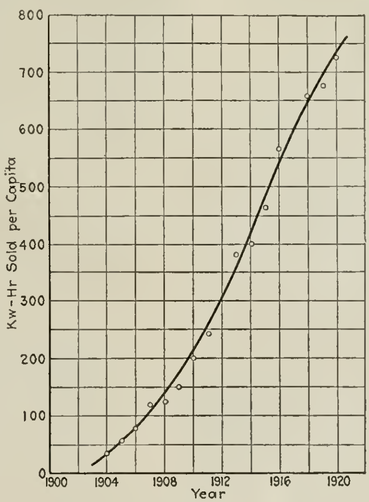

Fig. 1 Increase in Consumption of Electric Power in Detroit Between 1903 and 1920

Obviously the production of power by central stations is one of the important items in modern life, and the increasing extent of its use has reacted upon the industry of power generation in a most remarkable way. In the case of fuel-burning stations, to which these observations are confined, the development of more economical apparatus, the improvement of load factor, and the refinement of operating methods have all been such that there has been an almost continuous decrease in the cost of production per unit of output. It should be understood that this decrease results not only from the more economical use of fuel, but also from better use of capital and labor. It is of course common knowledge that the selling price of electrical energy has recently risen in practically all parts of the country. This has been due to abnormal prices of all materials, supplies, and labor, as well as to the attitude of labor toward its work. These things are probably all temporary, and it is expected that their effects will disappear in due time.

Three things have had a predominating influence in bringing about these results, namely—

a Improved load factor

b Increasing size and efficiency of steam turbo-generators, and

c The introduction of efficient mechanical stokers.

It is difficult to give average values for the purpose of showing load-factor improvement because conditions vary greatly from place to place and time to time. However, it will help somewhat to point out that as a central electric supply changes from a pure lighting to a combined lighting and power supply, the load factor changes from something of the order of 10 per cent or less to a value between 50 and 70 per cent. Obviously capital charges per unit of output in the first case are extremely heavy when compared with capital charges in the second case.

The size and efficiency of steam turbo-generators are, of course, readily expressed in numerical form. Fig. 2 is given to illustrate the marvelous developments which have occurred within two decades.

The introduction of efficient mechanical stokers has had two quite different effects. The boiler-room thermal efficiency has been increased to a remarkable degree and the size of units has grown tremendously. In 1900 most central stations were equipped with boilers containing not over 5000 sq. ft. of heating surface. This size has been increased gradually until now units containing between 12,000 and 24,000 sq. ft. are in common use. Paralleling the increase in thermal efficiency and in size, there has been an increase in the efficiency of use of boiler-room labor. It is now possible for one fireman to take complete charge of 5000 rated boiler horsepower.

Limit of Development Along Old Lines Practically Reached

At the present time we seem to have reached very close to the limit of ultimate development along the lines which have been followed during the past two decades. This statement, however, is not meant to imply that there is no further room for improvement in central stations as they now exist. Obviously, no central station not built within the past year or two can contain all the latest developments. Almost all central-station companies operate one or more old plants which could be improved by reconstruction. In many cases this reconstruction can be economically justified and is being carried on or is contemplated. Nor does it mean that we are unable to build more efficient plants than those just completed.

The real significance of the statement is this: Since about 1900 we have pursued a fairly consistent sort of development along fairly definite lines. During the entire period further possible improvements were always visible and one could predict with a reasonable degree of certainty that each suceeding year would produce certain definite modifications and advances. Now we seem to have reached a point where marked increase of economy in the use of money, labor or fuel can be made only by radical changes of some sort.

[1]Chief, Research Department, The Detroit Edison Company. Mem. Am. Soc.M.E.

Presented at a meeting of the Cleveland Section of The American Society of Mechanical Engineers, March 1, 1921. Slightly abridged.

Rather curiously we arrived at this point in the evolution of the art at just the time when there was the greatest need of conservation in the use of capital, fuel and labor. The driving force furnished by the excessively high prices for money, fuel and labor which have characterized the last two or three years would have been sufficient to cause improvements of tremendous magnitude had we known just what direction to take. Unfortunately we found ourselves at a sort of parting of the ways, and the best brains in the industry in this country and in Europe have been, and are, trying to map the road to be followed in the immediate future.

Out of the work already done have come several very definite indications, but the author cannot feel that any of them promise enough to justify us in concluding that they mark the way. Rather are they to be considered merely as the finishing touches to the existing type. It is his belief that we are just polishing off the steam-turbo-generator type, and that while we may be forced to continue doing so for quite a few years, we are essentially marking time while waiting for a new, epoch-making design, invention or development.

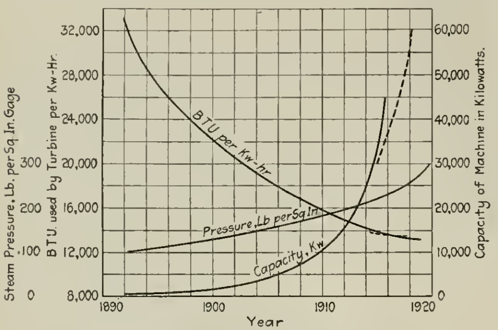

Fig. 2 Steam-Turbine Progress Since 1892
(Dotted lines refer to compound machines.)

There is nothing now in sight which promises any change so revolutionary as the introduction of the steam turbine or the stoker, but this must not be interpreted to mean that the author does not believe something of this sort is coming. He feels perfectly certain that development will be even more rapid in the future than it has in the past and that, as a result, the allowance for obsolescence should be made higher in the future rather than lower. With the foregoing paragraphs to serve as an introduction we may now enumerate and possibly evaluate the changes now occurring and those which are apt to occur in the near future.

All engineers who are familiar with the theory of steam engines and other heat engines know that theory indicates increasing thermal efficiency as upper and lower temperatures of the working substance are moved farther apart. In the case of the steam turbine this is equivalent to saying that the thermal efficiency will improve as the temperature of the steam reaching the unit is raised and as the back pressure, and therefore the temperature of steam leaving the unit is decreased.

We already have many stations operating with maximum steam temperatures of 600 deg. fahr. or higher and we are rapidly approaching a temperature of 700 deg. A value between 700 and 800 is generally considered to be the highest that should be used with the metals and alloys and the types of construction now available. In the opinion of the author 700 deg. fahr. is about as high as we can safely go at present.

At the other end of the temperature scale, we are now operating our best plants with an average back pressure throughout the year of about one inch of mercury, and there does not seem to be any possibility of greatly improving this performance.

Economic Possibilities in Use of Higher Steam Pressures

With the temperature limits thus definitely set and already practically attained, engineers have begun to consider seriously the possibilities of using higher steam pressures without exceeding the upper temperature limit. It is commonly known that the temperature of saturated steam increases with pressure, but the form of the curve connecting pressure and temperature is not generally appreciated. Such a curve is given in Fig. 3. It is obvious that temperature increases very rapidly with respect to pressure at low pressures, but that this relation is reversed at high pressures. At present a few central stations are using, or are being constructed to use, a pressure of from 300 to 350 lb. per sq. in. The curve of Fig. 3 shows that saturated steam at such pressures has a temperature well below 450 deg. fahr. If we assume it will be possible to utilize pressures as high as, say, 500 lb. per sq. in. in the near future, we will reach a saturation temperature only a little higher than 450 deg. fahr. To attain steam with a saturation temperature of only 600 deg. we should have to utilize a pressure of almost 1600 lb.

It is quite obvious that if we are to operate with the highest permissible temperature we must use superheated steam, even if we increase the maximum pressure to the highest imaginable limit. The curves of Fig. 4 are presented to indicate the theoretical possibilities of higher pressures.

It will be observed that the theoretical efficiency of the cycle increases with increasing pressure for both saturated and superheated steam. It will also be observed that at the temperatures to which we seem to be restricted the gain resulting from increasing the pressure from 200 lb. per sq. in. to 300 lb. is greater than for the next 100-lb. increase, and so on up to the highest pressures shown. Moreover, the maximum efficiency shown is not so much higher than the indicated for pressures and temperatures now in use that radical increase of pressure and temperature holds great promise.

A modern plant with steam pressure between 200 and 225 lb. and with a steam temperature of about 600 to 650 deg. fahr. can produce power at a cost of about 19,000 B.t.u. in fuel per net kilowatt-hour. If the same ratio between actual results and theoretical efficiency of cycle holds for higher pressures and temperatures, we should be able to produce a kilowatt-hour for about 17,500 B.t.u. with steam at 400 lb. and 700 deg. fahr. Taking probable extreme limits and assuming 600 lb. and 800 deg. fahr., the cost of a kilowatt-hour would be about 16,000 B.t.u.

Such figures are certainly worth striving for, but unfortunately they do not tell the whole story. First, the cost of equipment will certainly increase with pressure and, to a certain extent, with temperature. Increased thermal efficiency will therefore certainly be partly offset by increased capital charges. Second, the ratio of actual to theoretical turbine efficiency should decrease with increasing pressure, so that the thermal gain to be derived from high pressures must be discounted to a certain extent. Third, the increased boiler pressure means increased flue-gas temperatures

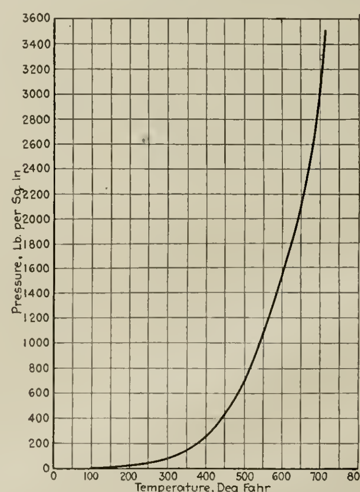

Fig. 3 Variation of Temperature of Saturated Steam with Pressure

and this must result in offsetting part of the calculated improvement. If this increased loss is prevented by the installation of a device like an economizer of air preheater, we have increased capital and operating charges to consider.

It is the author's opinion that it will be quite a while before we resort to pressures higher than 400 lb. and that fuel will have to cost much more than is probable for the immediate future, while capital must, if anything, cost less to justify exceeding such a value. Against this is to be set the fact that we are now using or preparing to use 350 lb. in this country and that in England they have already exceeded 400 lb.

Ferranti's Proposed Turbine Cycle—The Emmet Mercury Boiler

Many years ago S. Z. Ferranti suggested an interesting modification of the turbine cycle. He proposed to add heat during the early part of the expansion so as to maintain the steam at a constant temperature during that part of the cycle. Practical difficulties led to a modification which has to most people obscured the original suggestion. In the modified form the steam is permitted to expand in the same way as it is now customary, but is completely withdrawn from the turbine at different points, reheated, and returned to continue the expansion. In theory this cycle promises an improvement of about 10 per cent over the cycle now in use. If actually used in an operating plant it is probable that not over 5 to 6 per cent improvement could be shown. Against this would be chargeable increased capital costs and increased operating complications.

It is rumored that this cycle in a simplified form is to be used in a new English plant now under construction. It has actually been used in experimental apparatus, and according to reports the results were satisfactory.

Another interesting suggestion emanates from W. L. R. Emmet. Many binary cycles have been proposed and thermal savings can be calculated for most of them, but the one suggested by Emmet seems to be the most promising. He proposes the use of mercury as one working substance and water as the other. The mercury is vaporized in a fuel-fired boiler something like a steam boiler, is expanded in a small turbine and condensed in a device which may be called a condenser-boiler. This device transmits the latent heat of vaporization of the mercury vapor to the water, converting it into steam which is used in a turbine in the ordinary way. Mercury boils at 677 deg. fahr. under atmospheric pressure and at 457 deg. under a pressure of 2 in. of mercury. It thus is ideally fitted to extend the upper temperature limit without introducing prohibitive pressures. It also has such other physical characteristics that a comparatively cheap turbine can be used.

This proposal of Mr. Emmet's is by all odds the most promising of the binary types and it seems to be the only one that warrants serious consideration at the present time. It promises a return of about 40 per cent more power from a given quantity of fuel, and this without a prohibitive increase in investment.

Results Effected by Employment of Mechanical Stokers

Turning now from a consideration of the turbine room to the boiler room, the introduction of the efficient and flexible mechanical stoker has reacted in two different ways. It has made it possible to obtain much higher boiler-room efficiency day in and day out, month after month, and it has made it possible to drive boilers at much higher ratings than were even dreamed of a comparatively short time ago. Increasing the quantity of steam which can be produced from a given equipment naturally reduces the overhead charges per unit of steam output.

Now the power producer does not care whether his power becomes cheaper because of more efficient use of fuel or because of more efficient use of capital. Consequently there is evident an increasing tendency to overstoker boilers and to drive them at high average rates. This is quite proper if it is not carried too far. Unfortunately the thermal efficiency of boiler units decreases with increasing output above a certain point, and if the rate of evaporation is carried far enough a point is reached at which decreased thermal efficiency and increased maintenance more than balance the savings in capital. The point at which this occurs differs with the character of equipment, the price of capital, the price of coal, the load factor and other considerations, but under average central-station conditions the most economical point will generally be found below 200 per cent of normal rating if economizers are not used. The addition of economizers naturally raises the proper value. It is probable that the cost of capital and apparatus will ultimately come down to prewar figures or very nearly to such figures, and it is equally probable that the cost of fuel will not. Under such circumstances the economic balance will probably be found to occur at a lower average rate of evaporation than some designers have expected.

Economizer Problems

One of the principal losses occurring with high boiler ratings results from high flue-gas temperature. This loss can be partly recovered by the use of economizers. However, economizers cost money to install, money to maintain and money to operate, and the waste is not therefore entirely recoverable. Some designers of power plants appear to give inadequate weight to some of the costs incurred in the practical operation of economizers.

It is rather interesting to note in passing that despite the increase in the price of coal during the past six years, the situation with respect to the installation of economizers has not materially

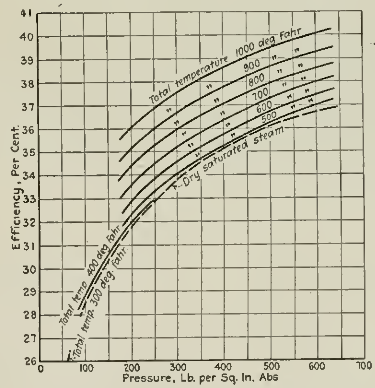

Fig. 4 Efficiency of Complete Expansion Cycle as Used in Steam Trbines (Back Pressure. 1 in. Hg.)

changed. The author knows of cases in which quotations on economizers increased during the same period at such a rapid rate that despite the increasing cost of coal the installation of economizers could not be justified. This is probably a transient situation; the cost of economizers may be expected to drop to a point which will place them in a much more advantageous position than that occupied before the war.

But here we are faced with another complication. Economizers until quite recently were made of cast iron exclusively. As the steam pressure in use has risen more and more, engineers have begun to question the propriety of using cast iron for such apparatus. It seems certain that all will agree that if we adopt pressures like those we are now considering, cast iron will be ruled out unless we operate economizers at a pressure much below the boiler pressure. This introduces undesirable complications.

Such considerations have led to the construction and use of wrought-steel economizers. These can be built with factors of safety equal to those used in boiler construction; they are practically as satisfactory as cast iron with respect to corrosion on the gas side, but are much more apt to corrode on the water side. In fact, it is possible to cause failure of steel economizer tubes by corrosion on the water side within a year.

In modern plants such corrosion is generally due to dissolved oxygen and can be prevented if proper precautions are taken to keep the boiler feed sufficiently free of this gas. There are now several well-recognized methods of doing this.

Air Preheaters

Within the past few years another device has been introduced for conserving heat otherwise lost in flue gases. This is the air preheater. Air used for combustion must be heated to furnace temperature from the temperature with which it enters the furnace. Ordinarily this is done in the furnace at the expense of heat liberated by the fuel. That part of this heat which is required to raise the temperature to a value equal to that with which the flue gases leave the boiler is wasted through the boiler damper.

If a large fraction of this heat could be conserved by transferring it from flue gases to entering air by means of an air preheater, a fuel saving of 10 per cent or more could be made. It does not seem probable that any such complete transfer can be effected in a real case, but some fraction of it is certainly attainable. It appears as though a saving of 3 to 5 per cent might prove possible.

However, this device also introduces problems of its own. It can be built comparatively cheaply, but its use involves additional flues and fans and power for driving the fans, so that the gross thermal gain in any case will be partly offset by increased thermal expenditure and increased capital charges. Further, it seems certain that air preheaters will present new cleaning and maintenance problems which will also yield items of expense which must be balanced against the gross thermal saving.

In addition to all these considerations we have another which may prove of still greater importance. We do not yet know the limiting temperature to which it is permissible to raise the air. The air supplied for burning fuel on the grate or stoker passes through that device and serves to cool it by removing heat which is radiated and conducted to it. It is certain that we can use air temperatures higher than those now common, but whether we will find 150 deg. fahr. or 300 deg. or 500 deg. to be the upper limit, is still unknown. The author is inclined to think that the upper limit will vary with the type of stoker and it is obvious that it will vary with the rate of combustion.

Feedwater Heating

Great improvements have been made in the character of boiler feedwater used in the large plants of the country in the past decade. In the early days we used for boiler feed or make-up water anything which was readily attainable. If the scale deposited in the boiler was of such character as to cause too much trouble, we treated the water chemically before use. But we still concentrated a chemical solution in our boilers, had to blow down at frequent intervals and were forced to shut down and thoroughly clean them out periodically.

We have now greatly improved this practice in the case of plants using surface condensers. In such plants the greater bulk of the water evaporated in the boiler is used over and over, being contained in what one might call a practically closed circuit. There is a certain loss from leakage, blowdown, spillage, etc., but this can be kept down to a value between 1 and 2 per cent of the total boiler feed by careful management. The make-up required to make good this loss is now commonly distilled and enters the system as a vapor, leaving dissolved salts behind in the evaporator.

With a plant operated in this way there is practically no deposit in the boiler. As a result blowdown losses are practically eliminated. Of still greater importance, however, is the fact that the expense of shutting down, opening up the boiler and turbining the tubes is almost completely done away with. In this case the improvement results not so much in a thermal gain as in decreased labor and maintenance charges and better use of invested capital.

Much thought has also been given recently to different methods of obtaining auxiliary power and to different methods of heating the feedwater. These factors are closely tied to the use of economizers and air preheaters, and that method which is best under one set of conditions is not necessarily usable with a different type of plant.

We seem to be settling down to two different types, although the whole subject is as yet admittedly in a state of flux. In the one type steam-driven house generators are used to supply some or all of the auxiliary power. The steam exhausted heats the feedwater in heater-condensers operating at such a vacuum as to give a feedwater temperature sufficiently low for advantageous use in economizers. In the other type the feedwater is heated by steam withdrawn from the main unit. This heating is preferably done in stages, and if the idea is carried to the limit, it results in the introduction of a cycle which is theoretically more efficient than the simple, so-called Rankine cycle now in use. Unfortunately, if this arrangement is carried to the ultimate limit it yields feedwater with a temperature higher than can be used advantageously in economizers. It also has another disadvantage from the view point of the central station. Auxiliary power must logically be taken from the main bus and continuity of service is correspondingly jeopardized.

Utilization of Low-Grade Fuels

No consideration of the evolution of power plants would be complete without a reference to the work which is being done in an effort to make available for use the poorer grades of fuel. Stokers are continuously under development and we are already obtaining very promising results with fuels which only a few years ago were practically unusable. Further, many attempts are being made to introduce pulverized fuel into central-station boiler rooms, and one large new plant is being completely equipped for the use of such material. Much is promised by the pulverized-fuel advocates in the way of increased thermal efficiency, decreased labor charges, and ability to use poorer grades of coal. As yet the case is not proved, but the experience of the next five years should bring out the facts. Personally, the author believes that the preparation of the fuel for the burner must be greatly simplified and cheapened before pulverized coal can compete with good stokers under central-station conditions in most sections of the country, but it must be confessed that many engineers in the industry do not share in this view.

So much for the trend of the times in power-plant design. It will now be of interest to attempt to evaluate all the possible improvements in sight.

Future Possibilities in Plant Efficiencies

If we assume that we will continue to use steam turbines and other equipment of the present types, but that we will increase pressure and temperature to the limit and will introduce all possible heat-saving devices, we can lay down on paper a plant which should deliver a net kilowatt-hour for between 14,000 and 15,000 thermal units. This would correspond to overall thermal efficiencies of the order of 24 or 23 per cent. Our best plants of the present day give values of 18 to 19 per cent.

The author is certain that with the fuel prices which are to be expected in this country in the immediate future, such thermally efficient plants would not represent the best engineering or economic solution of the problem. The investment would in his opinion be higher than could be justified. On the other hand, he does expect to see a figure between 16,000 and 17,000 attained in the very near future.

In a number of cases of economizer installations made during the last few years it has been found that the fans were of too small capacity to handle the desired overloads. This has apparently been due in large measure to amounts of excess air much beyond what was expected. Some engineers figure 10 to 20 per cent air infiltration in an economizer setting alone, and there is often a large amount passing into the boiler setting, especially in a multiple header boiler. It is also frequently the case that smoke flues are far from tight, especially at riveted and expansion joints. One plant reports the infiltration between a large boiler and cast-iron economizer to be relatively small (about 500 to 2000 cu. ft. of air per minute), but the infiltration through the economizer casing and stack uptake to be greater, ranging from 4000 cu. ft. with air leaks cemented up to 20,000 cu. ft. in an extreme case. Another station, with steel-cased economizers, reports negligible infiltration. The result of high excess air is, of course, to increase the volume of the flue gases and also the draft required. As modern fans have definite draft-volume-speed characteristics, the results are often to throw the fan performance beyond proper limits.—From 1921 Report of the Prime Movers Committee of the National Electric Light Association.

Report on Elimination of Waste in Industry

Committee Authorized by American Engineering Council and Appointed by Herbert Hoover Points Out Wastes and Recommends Steps for Elimination

This report is the first work undertaken by The Federated American Engineering Societies in rendering public service. It discloses losses and waste due to the restraint and dissipation of the creative power of those who work in industry. It lays the foundation for knowledge of the destructive influences which have too much controlled in the past. From this knowledge will grow the conviction that mental and moral forces must be added in a much larger degree to the physical resources now employed if industry is to serve all who are dependent upon its continuous and effective operation.

The Committee believes that this study of waste in industry will prove of lasting benefit to the industries studied and to the public which uses their products. It hopes further that the benefits will be farther reaching, and will extend to other industries by stimulating similar studies and outlining the methods by which they can be made. The Committee believes that such additional studies will prove of great value and that through intelligent application of conclusions reached American industry will take another long stride in advance. In expressing these beliefs the Committee recognizes that many of its findings and recommendations have previously been pointed out by individual engineers, but this report is the first instance of a collective or group endorsement of a general analysis of the sources and causes of waste and recommendations for its elimination.

THE preceding paragraphs appear in the preface of the Report of the Committee on Elimination of Waste in Industry. This Committee was authorized by the American Engineering Council, the executive board of The Federated American Engineering Societies, soon after its organization in the fall of 1920, and on January 12, 1921, Herbert Hoover, as President of the American Engineering Council, appointed its members. At present the Committee consists of the following men: J. Parke Channing, *Chairman*, L. W. Wallace, *Vice-Chairman*, L. P. Alford, George D. Babcock, Wm. R. Basset, F. G. Coburn, Morris L. Cooke, Harrington Emerson, Ira N. Hollis, Herbert Hoover, Edward Eyre Hunt, C. E. Knoeppel, Robert Linton, Fred J. Miller, H. V. R. Scheel, Sanford E. Thompson, John H. Williams, and Robert B. Wolf.

The Committee determined to gather quickly such concrete information as might be used to stimulate action and lay the foundation for other studies. It was believed that a limited, yet carefully studied, volume of findings obtained through a rapid intensive study would not impair the value of the facts disclosed or the validity of the recommendations based thereon, so within five months the Committee completed the assay of waste in six branches of industry and on June 3 presented a summary of its findings to the American Engineering Council. The final report was released for publication on July 15 and printed copies are expected to be issued about the middle of September.

There were three outstanding difficulties in the study of industrial waste: the extent of American industry, the fact that there is no accepted management or labor terminology, and the lack of a method of weighing the performance of industry. The impossibility of making a comprehensive study of the nearly three hundred thousand industrial plants grouped in the census into fourteen major classes is obvious. Neither time nor funds were available for such a task, and even if it might have been attempted, it is doubtful if the results would have been commensurate with the expenditure. Therefore the decision was reached to make a study of a group of representative plants in several industries, whose operation directly affects the daily life of every one. The lack of standardized terminology and of units and methods of measurement was overcome by preparing a standard method of investigation to be used in each branch of industry and in the plants in which intensive studies were made.

The limitations of the study in the industries selected are indicated in the following tabulation:

Branch of In'ustry	No. of Plants Investigated	No. of Plants Furnishing Additional In'ormation
Building Industry	73	33
Men's Ready-Made Clothing Manufacturing	9	—
Boot and Shoe Manufacturing	8	25
Printing	6	19
Metal Trades	16	17
Textile Manufacturing	13	—

The plan of study followed in each of these six branches of industry was this: At the outset the members of the Committee prepared an analysis of those factors and operations in industry in which waste might be expected to be discovered, provided a comparison was made between average practice and the best known practice. From this analysis a trial questionnaire was prepared to secure information and quantitative data to permit of comparing the record of one plant with another.

This trial questionnaire was then used in making a study of one plant in each industry. The results of these trial studies were then brought together, compared, reviewed by the Committee and, as a result, a revised questionnaire and an evaluation sheet were prepared, to be used in making the studies upon which this report is based.

This revised questionnaire, as used with suggested modifications based on the experience accumulated in its use in the field studies, forms an important part of this report. Wherever it has been used, plant managers have shown marked interest, which has led the Committee to include it in the printed report.

The printed report will be a book of about 130,000 words, divided into three sections: the first, a summary, which will include a statement of the sources and causes of waste with recommendations for waste elimination; the second, the engineers' field reports in the six industries investigated; and the third, general reports on unemployment, strikes and lockouts, legal machinery for adjusting disputes, industrial accidents, health of industrial workers, eye conservation, and purchasing and sales policies. all of which support from a broader point of view many of the specific findings presented in the field reports and for this reason give a more general background for many of the recommendations offered.

Section I, the summary of the report, is presented in abstract below, the omitted material being explanatory or corroborative of the statements printed.

Summary of the Report

IN making the studies upon which this report is based and in preparing the report itself there has been no purpose or desire to place blame upon any individual, group or class. The wastes revealed are the result of methods, tactics, practices and relationships of long standing in industry and the Committee has merely desired to indicate the main opportunities for eliminating waste and to show whose opportunity or responsibility it may be to adopt proper measures for such elimination.

No attempt has been made to write an academic definition of waste or to speculate in regard to ultimate savings. For the purpose of this report no attempt has been made to consider all economic wastes. Rather, in the Committee's investigations *industrial waste has been thought of as that part of the material, time and human effort expended in production represented by the difference between the average attainments on one hand and performance actually attained on the other as revealed by the detailed reports.* In assaying waste in industry the Committee has undertaken to evaluate this difference. Thus it has established no theoretical standard of performance or excellence, but has developed a method of measurement to determine the degree of effective use of those factors within which it was believed waste might be discovered. It has conceived that a given practice is not wasteful until a better has been revealed, and that the value of a newer practice, or the amount by which it is an improvement over an earlier one, can only be determined by units and methods of measurements.

SOURCES AND CAUSES OF WASTE

Waste in industry is attributable to:

1 Low production caused by faulty management of materials, plant, equipment, and men

2 Interrupted production, resulting from idle men, idle materials, idle plants, idle equipment

3 Restricted production intentionally caused by owners, management, or labor

4 Lost production caused by ill health, physical defects and industrial accidents.

Relative Responsibilities. Management[1] has the greatest opportunity and hence responsibility[2] for eliminating waste in industry. The opportunity and responsibility of labor is no less real, though smaller in degree. The opportunity and responsibility chargeable to outside contacts cannot be so clearly differentiated or evaluated. The relative measure of these is shown by the quantities in the following table which come from the composite evaluation sheets in the engineers' field reports:

Industries	Responsibility Assayed Against Management, Points[3]	Labor, Points	Outside Contacts,[4] Points	Total Points
Men's Clothing Mfg.	48.33	10.50	4.95	63.78
Building Industry	34.30	11.30	7.40	53.00
Printing	36.36	16.25	5.00	57.61
Boot & Shoe Mfg.	30.25	4.85	5.83	40.93
Metal Trades	23.23	2.55	2.88	28.66
Textile Mfg.	24.70	4.70	19.80	49.20

From the preceding table are derived percentage values for each of the agencies against which responsibility is assessed, as follows:

Industry Studied	Responsibility Assayed Against Management, Per cent	Labor, Per cent	Outside Contacts,[2] Per cent
Men's Clothing Mfg.	75	18	9
Building Industry	65	21	14
Printing	63	28	9
Boot & Shoe Mfg.	73	11	16
Metal Trades	81	9	10
Textile Mfg.	50	10	40

The quantities presented above justify the following statement: Over 50 per cent of the responsibility for these wastes can be placed at the door of management and less than 25 per cent at the door of labor, while the amount chargeable to outside contacts is least of all.[5]

In every industry studied there are outstanding examples of good management, but the bulk of the industry does not approximate this standard. In the clothing industry, for instance, one plant was rated by the engineers 57 points higher than the worst one studied and 42 points better than the average.

The following table gives a comparison, for each industry studied, of the total number of points assessed as waste in the best plant investigated, compared with the average of all the plants:

Industries	Points Assayed Against Best Plant Studied, Points	Average of All Plants Studied, Points	Ratio of Best to Average
Men's Clothing Mfg.	26.73	63.78	1 : 2
Building Industry	30.15	53.00	1 : 1¾
Printing	30.50	57.61	1 : 2
Boot & Shoe Mfg.	12.50	40.83	1 : 3
Metal Trades	6.00	28.66	1 : 4¾
Textile Mfg.	28.00	49.20	1 : 1¾

These tables present the consensus of opinion of the engineers engaged in field studies to the effect that the average of management is much below the standards set by certain individual executives who have achieved notable success.

It must not be assumed, however, that these points or ratios are valid in comparing the waste in one industry with that in another. They are useful only in making a comparison of waste in plants within the industry where they were assessed. Further, the quantities disclosed by the evaluation sheets are only a part of the findings dealt with in this report.

Waste Due to Low Production

Faulty Material Control. In certain industries the waste of materials is a serious drain on production, a fact which is revealed by a comparative study of plants in the same field. The methods of control which are common in the shoe industry account for the greatest loss in shoe production, with the possible exception of seasonal demand and production. The loss from idleness in shoemaking occasioned chiefly by waiting for work and material amounts to some 35 per cent of the time. The average building contractor has no calendar of operations except the dates of starting and finishing a job. He largely regulates deliveries on materials by visits to the job, or through statements received from the job superintendent. Still another waste from inadequate material control comes from the speculative purchasing of raw materials.

Faulty Design Control. The defective control of design results in a major waste, since it prevents standardization of product. Standardization of the thickness of certain walls might mean a saving of some $600 in the cost of the average house. Standardized mill work, such as window frames, doors and other similar items, would reduce the cost. In the printing trades there is wide variation in flat-bed cylinder presses; there are more than six hundred types of folding machines. Formerly each type foundry cast its type on a more or less different body, and although the change from the old system to the point system involved an expenditure of some $3,000,000 by the type founders, it is universally conceded that this expenditure has been saved many times over. Such examples point the way to further efforts.

Another source of waste through inadequate design control comes through defective drawings, specifications and tolerances.

Faculty Production Control. The lack of adequate methods of production control is evident in every industry studied. It is one of the outstanding weaknesses.

In the men's clothing industry it is found that at least ten hours per week per man is thrown away on energy-wasting and time-wasting work resulting from lack of shop methods, while an additional two or three hours per man per week is wasted in unnecessary work. Fixing the value of annual output in the men's ready-made clothing industry at $600,000,000, it should be relatively easy to save three-quarters of a million dollars a day, an increase of 40 per cent in effectiveness.

The lack of production control is not a question of large versus small plants. In the metal trades, for example, the engineer declares that the size of the plant does not necessarily determine its efficiency, for some of the large plants as well as some small ones show a large waste factor.

Lack of Cost Control. The majority of the industrial plants studied lack a knowledge of costs and have no cost control. Therefore there is no adequate method of judging fairly and accurately when improvements are needed and when waste is occurring. Not having the facts prevents prompt correction of defects. The above conditions are disclosed, for example, in the report on the metal trades.

Lack of Research. While certain industries are ahead of the rest in plant research, the need for more intensive research activity is apparent in every industry. One industry which is backward in this respect is clothing. In the majority of men's clothing plants nothing approximating research is practiced to improve materials, processes, equipment or product. The assertion probably will not be challenged that there is not a single individual throughout the entire industry who is solely engaged in research, and is thus without operating duties.

In the shoe industry there is lack of information as to market demands in this country and abroad. In all the leather industries there is need for scientific research to aid in predicting the kinds and quantities of leather required.

Faulty Labor Control. With perhaps two or three exceptions, shoe shops have no departments maintaining modern personnel relations with the employees. In the shoe industry the cost of training an inexperienced man for cutting upper leather in a well-managed shop is $576; for a semi-experienced man, $450; and to

[1] The term "management" as used in this part of the report refers to the agency (owners or managers) which exercises the management function in industry. This function is defined in a report approved by the Management Division of The American Society of Mechanical Engineers as:

"Management is the art and science of preparing, organizing and directing human effort applied to control the forces and to utilize the materials of nature for the benefit of man."

[2] The "responsibility" of a given agency as here used does not mean moral responsibility as ordinarily understood, but only that responsibility which arises from the undeniable fact that a given cause of waste can be removed only by a particular agency. "We measure responsibility not by the thing done, but by the opportunities which people have had of knowing better or worse."

[3] The relative responsibilities have been evaluated in "points." A theoretical total of 100 points represents all possible waste. As no plant is or could be entirely wasteful, the number of points assigned in any case must be less than 100.

[4] The public, trade relationships, and other factors.

[5] Adjusted by field engineer to a basis comparable with the other field evaluations.

install an experienced man in a different shop costs $50. For the average shop these figures are unquestionably low.

The average labor turnover for the year 1920 in the metal-trades plants covered (wherever records were kept, which was the case in less than half of the plants), was 160 per cent—figured in most cases as the ratio between the number of "separations" and the average number of employees on the payroll. The highest turnover was 366 per cent.

The building trades have given little consideration to the subject of labor turnover. In construction work it is particularly difficult to estimate the extent, because the actual percentage of turnover constantly varies as the building progresses and the number of men is increased and later decreased. Employment managers are rarely employed even upon the largest jobs, and "hiring and firing" is at the will of the foreman or superintendent.

Another fault in labor control is improper or inadequate rate setting. In negotiations and controversies between employer and operator in the shoe industry, what stands out is the lack of knowledge of facts which can be used as a basis for setting rates.

Ineffective Workmanship. Still another loss resulting in low production arises from inefficient workmanship. For much of this management is responsible through failure to provide opportunities for education or special training. Management cannot, however, do more than provide these facilities, and experience has shown that it is difficult to interest workmen in training courses which are designed to increase effectiveness. Further, much ineffective workmanship arises from lack of interest in work or lack of pride in good workmanship. The field reports give no evaluation of spoilage, which is one of the measures of this form of waste.

Faulty Sales Policies. The cancellation of orders is a condition peculiar to certain industries. It is especially acute in the clothing industry. Purchasers buying on long-time contracts return unsold goods at the end of the season, and claim and receive credit. The evil is general in the clothing and allied industries. It is common practice for manufacturers to oversell the dealers and oversell their own manufacturing capacity. They make and deliver what they can, and cancel the rest of their orders. The manufacturers follow the same bad custom in dealing with the textile mills.

The committee realizes that before there can be a material reduction in the sum total of waste in industry, much earnest, painstaking work must be done. The solution of such a problem is not one of hours or days but of years. Fundamental changes in our economic, financial, managerial and operating concepts and practices will be required. There will be need of both coöperative and individual effort. As regards groups, each must frankly face its own responsibility and meet its own duties. Each individual—plant executive or worker—must discover his own opportunities and then accept responsibility for performance. To such a one, the Committee on the Elimination of Waste in Industry suggests that the methods developed for investigating and compiling the information as revealed in this report be utilized in individual plants to show the way for betterment and improvement.—WASTE REPORT.

Waste Due to Interrupted Production

Idle Men. The amount of idleness or unemployment in industry can only be evaluated through rough estimates. There is no national machinery for collecting the facts. In the best years, however, even the phenomenal years of 1917 and 1918 at the climax of war-time industrial activities, when plants were working to capacity and when unemployment reached its lowest point in 20 years, there was a margin of unemployment amounting to more than a million men. This margin is fairly permanent; seemingly one or more wage earners out of every forty are always out of work.

During periods of industrial and business depressions, unemployment reaches its greatest amount. Such depressions appear more or less regularly at 7- or 10-year periods and each brings its increase in unemployment and wastage of the productive capacity of industry.

In January 1921 a nation-wide survey of employment made by the U. S. Employment Service of the Department of Labor showed that there were 6,070,648 workers then employed in industry as compared with 9,402,000 in January of 1920, a decrease of 3,331-352 or approximately 35.5 per cent. This survey covered 35 states and 182 industrial cities and centers and may be considered as fairly reflecting conditions at that time.

In addition to minimum and climacteric unemployment, many essential industries show a high unemployment or idleness once a year or oftener. Practically all industries are in a sense seasonal. To present a few examples: The clothing worker is idle about 31 per cent of the year; the average shoemaker spends only 75 per cent of his time at work; the building-trade workman is employed only about 190 days in the year or approximately 63 per cent of his time; the textile industry seemingly has regular intervals of slack time; during the past 30 years bituminous-coal miners were idle an average of 93 possible working days per year. In the brick, chemical and glass industries the percentage of full time worked was 85, 84 and 87, respectively. In most years the percentage of lost days is much larger.

Intermittent unemployment brings other wastes. One consequence is a concrete but fallacious industrial philosophy that there is only so much work to be done and that the sensible course of action is to retard production to make employment last throughout the year, or to uphold prices.

Another form of unemployment comes from open conflict between management and labor. Here it should be said that in the past, at least, the amount of waste from the general run of strikes and lockouts through loss of wages and curtailment of production has been less than is popularly supposed. That these disturbances do produce unemployment is true, but in the industries studied they do not of themselves appear to constitute a major source of reduced production. The ramifications of such strikes with their attendant and indirect losses the Committee has been unable to trace.

Since most strikes occur in seasonal employments, it can be deduced that output is not necessarily penalized, for it is often possible to make up the losses incurred by strikes through increased production at other times.

More coal was mined in 1910 than in 1911, although the former year witnessed many protracted strikes involving large numbers of employees. The year 1912, with 47 per cent of the entire labor force out on strike and with an average loss per man of 40 days, showed an increased output of coal per man per day and per year, and six days' more employment than in the year 1911, which, it will be remembered, was relatively strikeless.

In addition to the direct loss of time, however, there is a loss incurred through retarded production previous to and immediately following strikes.

Wages and hours have always been the chief cause of strikes. There has been a marked falling off in the relative number of strikes for this cause in recent years as compared with 1898-1905.

Jurisdictional disputes, that is, strikes by the members of one trade against the performance of work which they regard as belonging to their craft by members of some other craft or trade, are relatively unimportant. In the building trades jurisdictional quarrels represent one-quarter of the total number of strikes.

Idle Material. The waste of idle material through deterioration, obsolescence and carrying charges is large, particularly where there are great inventories of both raw material and finished goods. Unbalanced production is another notable cause of idle materials and consequent waste.

Idle Plants and Equipment. Unsound production policies result in wasteful overequipment. Clothing factories are built 45 per cent larger than is necessary; printing establishments are from 50 per cent to 150 per cent overequipped; the shoe industry has a capacity of 1,750,000 pairs of shoes a day, and produces little more than half that number; throughout the metal trades, standardization of products would permit of large reductions in plant equipment.

Standardization of machine sizes would make possible the use of one machine for a greater variety of different jobs.

It has not been possible in this assay to estimate the amount of idle equipment, nor the accompanying waste through maintenance and depreciation charges.

Waste Resulting from Restricted Production

Restrictions By Owners and Management. Some of the evils of restricted production are chargeable to owners and management. In the building trades the contractors, builders and supply dealers have restricted production by maintaining high prices, collusion in bidding, and unfair practices. At times there has been collusions between employers and labor, tending to raise prices unduly. The waste from these causes cannot be measured in this study.

Restrictions by Workers. Restrictions of individual output for which workers are responsible are susceptible of measurement. They are of two kinds. On the one hand, when workers are scarce. the less conscientious workers become independent and slacken speed, whereas when workers are plentiful, they work with greater diligence and care for fear of unemployment. On the other hand, the dread of unemployment is so pronounced that employees engaged in seasonal enterprises frequently restrict production in order to make employment last longer; some workers, moreover, through consideration of their fellow-employees, limit production to provide work for them, a practice which ultimately results in an economic loss.

The tools of the engineer are standard weights and measures, scientifically established. He cannot serve industry unless he can set standards for production and can measure work performed. Many unions now oppose the use of such standards. Practically all of the printing unions oppose these devices. The rules of the craft unions in the building trades also object to many labor-saving devices, and thus contribute to waste in that industry.

The restriction of the number of apprentices is a common rule. The rule requiring that members of one craft union shall not encroach upon the work of another results in large waste and little benefit. Unions frequently require three or four skilled employees to perform various operations on a plain job which a single worker could satisfactorily do by himself. Union carpenters are forbidden to lay bricks, union plumbers are forbidden to do carpentering work, and so forth. Unions are also charged with restricting the use of machinery.

A union rule in newspaper printing requires that all advertising matter coming into the plant in electrotype form must be reset by the compositors. This useless work is sometimes done weeks after the advertisement has appeared.

Waste Caused by Lost Production

Ill Health. In discussing public health conditions there is no clear distinction between the standing of the 42,000,000 persons classed as gainfully employed in the United States and those specifically engaged in industry. The 42,000,000 men and women gainfully employed probably lose on an average more than eight days each annually from illness disabilities, including non-industrial accidents —a total of 350,000,000 days. Of the 500,000 workers who die each year, it is probable that the death of at least one-half is postponable by proper medical supervision, periodic medical examination, health education, and community hygiene.

Assuming that the average life has, aside from all spiritual and human values, an economic value to industry of not less than \$5000, and assuming that the special diet, care, and medical attention required by a man chronically ill costs \$3 per day, it has been estimated that the economic loss from preventable disease and death is \$1,800,000,000 among those classed as gainfully employed, or over \$700,000,000 among industrial workers in the more limited meaning of the term.

Defective Vision and Defective Teeth. It is estimated that 25,000-000 workers have defective vision requiring correction. It is the experience of a number of plant executives that the correction of sub-standard vision brings increased quality and quantity of production, sufficient to pay for the cost. A very large proportion of workers have defective teeth and mouth infection, and other serious physical defects which reduce their effectiveness.

Industrial Accidents. In 1919 there occurred in industry about 23,000 fatal accidents, about 575,000 non-fatal accidents causing four weeks or more of disability, and 3,000,000 accidents causing at least one day's disability. The time lost is estimated to be 296,000-000 days, giving an economic loss to the country of about \$853,000-000 for the year 1919. This does not include the costs to employers and employees for medical and surgical aid and hospitals' bills, and the overhead expenses of insurance.

RECOMMENDATIONS FOR THE ELIMINATION OF WASTE IN INDUSTRY

In preparing this third part of the summary, the Committee has endeavored to interpret responsibility in terms of what might be done to eliminate waste in industry. The policies and methods recommended are such as are already in successful use in the industries and plants investigated.

Responsibility of Management

Improvement of Organization and Executive Control. Planning and control should be adopted as fundamentals of good management. For the most part they have not as yet penetrated the mass of American industry.

Production Control. Conscious production control tends to reduce or eliminate waste by shortening the total time of production. Material schedules should be installed and used. Work in process should be planned in advance by methods which will insure its timely delivery to the machine or operation where it is needed, so that there will be no idleness between jobs.

Balancing Productive Capacity and Demand. The sound relation between capacity and demand is shown only as a wise policy is adopted in regard to planning, routing, and scheduling work, and as improved shop methods are put into effect.

Development of Purchasing Schedules. There should be the same coördination of the purchasing function and careful control of material purchased and not yet received as is given to material already in the plant.

Elimination of Cancellations and Curtailment of Returns. The practice of cancellation of orders between manufacturer and customer should be eliminated and there should be a curtailment of the privilege of returning goods ordered and received.

Correlation of Production Schedules with Sales Policies. Production schedules should be based on a carefully formulated ales policy determined from an intensive study of markets, thus stabilizing production.

Inspection. The aggregate annual wastage of human effort and goods from spoiled and defective work is appalling. The indirect losses, which are harder to detect and measure, are often greater than the direct losses.

Maintenance of Plant and Equipment. Upkeep of plant is conducive to maximum production, as it assures that equipment and machinery will be continually in a condition to operate.

Uniform Cost Accounting. In controlling production and in judging fairly and accurately when and where progress and improvement are being made, the lack of a good cost-control system is necessarily a source of much waste.

Methods of Wage Payment. Methods of wage payment should be adopted, equitable and just in their basis, and insuring a proper relationship between effort put forth and results achieved by all who participate in the enterprise.

Standardization of Product. Products should be standardized, consistent with progressive development of manufacturing.

Standardization of Materials. Materials should be standardized to the fewest practicable kinds, sizes and grades.

Standardization of Equipment. At least the details of equipment, including machines and tools, should be standardized so as to permit of the widest interchangeability and maximum usefulness consistent with improvements in design and invention.

Performance Standardization. Performance standards should be developed as a valuable aid to planning and production control.

Management and Workers. Management has a definite responsibility in selecting, upgrading and in maintaining personnel. Experience indicates that the best results can be obtained when employment and personnel direction develops a sense of mutual interest in production on the part of management and workers.

Prevention of Accidents. Management has a definite responsibility to prevent industrial accidents. Systematic preventive measures can and should be inaugurated.

Research. The need for knowledge obtained by industrial research was manifest in every industry studied.

Responsibility of Labor

Increasing Production. The need for facts instead of opinions stands out everywhere in the assay of waste from intentional restrictions of output. No service which workers can render can be socially more valuable than that of studying the needs of the industries in which they earn a livelihood, and allying themselves with the technicians who serve with them to increase production which will inure to the ultimate benefit of all.

Standardization of Work. Labor should coöperate to prepare for and even demand the determination of and use of performance standards.

Changing Rules Regarding Restrictions. Labor should change its rules regarding restriction of output, unreasonable jurisdictional classifications, and wasteful methods of work, thereby removing some sources of waste.

Improving Health and Reducing Accidents. Labor is responsible no less than management for improving the health of the workers and for preventing accidents in industry.

Improving Industrial Relations. Inasmuch as the organization of personnel relationships in industry can only be accomplished through the coöperation of both employer and employee, labor should assist in such work of organization and in maintaining and utilizing the structure developed.

Responsibility of Owners

The owners of industry, through the banking function or otherwise, share in the responsibility for eliminating waste in industry. They have the duty particularly of assisting in stabilizing production.

Responsibility of the Public

Need of Public Interest. In the study of industrial waste, there can be no setting apart of the public as a separate group. A campaign to increase the productivity of industry cannot be conducted without widespread interest and support.

Style Changes. In certain industries the consuming public is to a degree responsible for seasonal fluctuations because of the eagerness with which it accepts or adopts changes in style.

Distribution of Demand. The public can assist in stabilizing industry by accepting a sensible distribution of demand throughout the year.

Community Coöperation With Industry. Public and semi-public agencies can assist by definitely encouraging and supporting the efforts for elimination of waste. Bodies such as local chambers of commerce and other civic and community associations can bring influence to bear through local conferences with the different branches of industry.

Opportunity of Trade Associations

Trade associations should be formed in those industries lacking comprehensive organizations. They should promote programs for the standardization of cost-accounting methods, the introduction of standardized material specifications, the establishment of production standards, the standardization of equipment, and the standardization of finished products.

Opportunity for Governmental Assistance

National Industrial Information Service. A national industrial information service should be established to furnish timely, regular, and complete information on current production, consumption and available stocks of commodities, supplementing the work of private agencies.

A National Statistical Service. A national statistical service should be established and maintained covering employment requirements and conditions throughout the country.

Principles for Adjustment and Settlement of Labor Disputes. A body of principles for the adjustment of labor disputes should be accepted which can be developed with experience.

Public Health Policy. The reports dealing with health, prepared in connection with this study by a group of physicians, declare for an aggressive, continuous, national public health policy.

National Program for Industrial Rehabilitation. The national program for industrial rehabilitation should be encouraged. It should offer opportunities for the education and placement of those having physical and mental defects as well as those handicapped by industrial accidents or by war. Formerly such incapacitated men were treated as if they had no economic value. Many striking examples, however, have led to the conviction that many such men can be so trained as to make them useful workers. Comprehensive efforts for their vocational rehabilitation are being made through the coöperation of Federal, State, industrial and commercial agencies.

Nation-Wide Program of Industrial Standardization. A nation-wide program of industrial standardization should be encouraged by the Government in coöperation with industry. In the standardization of design of product, methods of procedure and number of models, there rests a large opportunity for the reduction of waste.

A special service which the Government can render in this connection is the standardization of its own demands. Several government departments have their own paper specifications, for example, with no relation to each other, or to any standard brand. These departments might well take the first step by standardizing the paper they use on the basis of a selected list of well-known brands.

It is not sufficient, however, to attempt to standardize the product of a given industry, for almost every industry is so dependent upon others that they too must coöperate. The Federal Government could call together the representatives of the trade associations of interdependent industries and in coöperation form committees for this purpose. The opinions or decisions of such committees might from time to time be promulgated as standards of practice.

Revision of Federal Laws. Where Federal laws interfere with the stabilization of industry, they should be revised in the interests of the whole people.

The largest area of waste lies in the periods of slack production and unemployment, due to the ebb and flow of economic tides between booms and slumps. Studies of industries as a whole show that we usually expand our equipment at the periods of maximum demand for products instead of doing our plant expansion during periods of slack consumption. While it cannot be expected that all industry could be so stabilized as to do its capital construction in slack periods, there are some industries which could be led in this direction by coöperation with the Government and coöperation among themselves.

As a striking example, in a seasonal industry such as coal mining, no adequate solution regarding stabilization can be found except through organized coöperation of operators, labor, railroads and large consumers. Under existing laws as to combinations, such coöperation cannot be carried out. Therefore, we believe that federal legislation is necessary permitting such coöperation under competent government authority.

Duty of Engineers

The duty of engineers is a part of all the responsibilities previously stated in different recommendations.

Engineers come in contact with and influence every activity in industry, and as a body possess an intimate and peculiar understanding of intricate industrial problems. They are in a position to render disinterested service, and their peculiar responsibility is to give expert judgment wherever engineering training and technical skill are needed to reach a just decision.

This report brings forward certain pressing problems concerning the solution of which engineers should hasten to assist. The assays of waste show first the need of definite and quantitative industrial information on a multitude of points. Science has pushed ahead in some directions; it lags behind in others. The duty of the engineer is preëminently a duty to enlarge the boundaries of knowledge. His lifelong training in quantitative thought, his intimate experience with industrial life, leading to an objective and detached point of view, his strategic position as a party of the third part with reference to many of the conflicting economic groups, and above all his practical emphasis on construction and production, place upon him the duty to make his point of view effective.

It is peculiarly the duty of the engineers to use their influence individually and collectively to eliminate waste in industry.

Die Sinking and Metal Patternmaking by Automatic Machine

By JOSEPH F. KELLER,[1] BROOKLYN, N. Y.

WHILE the term "die" is very comprehensive and elastic and is applied to an endless variety of tools, it is to be understood that the methods discussed in the present paper have to do with such dies as are used for stamping, forging, embossing, pressing, etc.; that is to say, such dies as contain the negative or positive of the product to be formed or decorated.

Among the industries to which such dies or molds are a fundamental necessity are the following: Arms and ammunition; aluminum ware; automobile parts; brass goods; buttons; compositions such as celluloid, bakelite, hard rubber, etc.; cutlery; die casting; drop forging in steel, bronze, brass, etc.; electrical appliances, glassware, pressed or blown; hardware; harvesting machinery; horseshoes; jewelry; lighting fixtures; medals; metal wares in general; paper goods; silver, flatware and hollow ware in all its branches; surgical instruments; toys, dolls, etc.; tractors; valves and fittings.

When the enormous expansion and development of the industries enumerated is borne in mind, the greatly increased demand for dies and die production is readily understood. Quantity output of uniform quality is possible only with machine-tool and die methods, and every manufacturing industry is forced to resort more and more to such methods to offset high labor costs and unprecedented operating expense.

How, then, are the world's die requirements to be satisfied? How, in fact, are the present demands being met? The answer here, as it has been to so many other industrial questions, is, by machinery.

The Various Methods Employed in Die Sinking

The die-making problem has been solved by a development of the carving machine, often conveniently, if inaccurately, spoken of as operating on the pantograph principle—that of the guide or tracer following the undulation of a pattern, causing the corresponding movement of a cutting tool, and thereby reproducing the pattern in the material on which the cutter operates. The greatest difficulty encountered in this work was to retain sensitiveness in combination with heavy cutting.

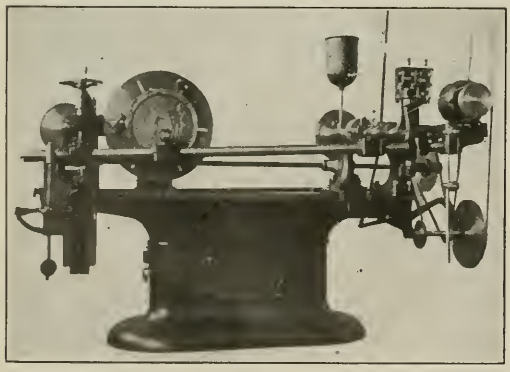

Fig. 1 Small Motor-Driven Reducing Machine Cutting Die for a Medal

Other methods such as machine etching, hot sinking, cold typing, etc., have come up from time to time. Some proved to be quite alluring at the beginning with the usual resultant disappointments after certain inherent difficulties began to be better understood.

The machine-etching method in connection with an electric current, long ago abandoned, is now generally conceded to have been of no practical value.

Hot sinking on the order of the Champney process is still in use to some extent, but its field of application is gradually growing less with the improvement and development of the more positive cutting method.

Cold typing or hubbing has been until recently very limited in scope and could only be used where a small amount of stock was to be upset. An attempt at deep sinking is always accompanied by the risk of splitting, which is usually apparent; or of destroying the steel structure. This latter condition is frequently not noticed until the die has been hardened and put into use.

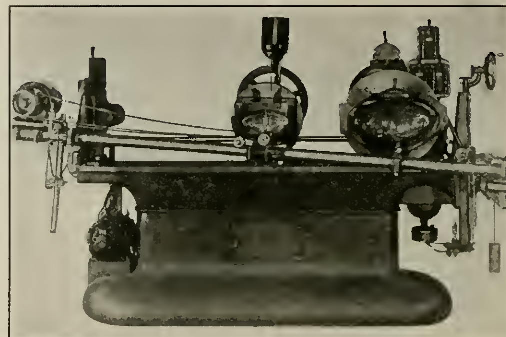

Fig. 2 Large-Size Motor-Driven Reducing Machine Cutting Die for an Ornamental Bowl

In connection with the die-sinking machine, however, the typing method has proved very practicable, and especially useful for silver flat ware, for dies for composition products, and for die casting with multiple inserts, also for many kinds of drop-forge work—in fact, wherever a number of accurate and interchangeable die reproductions are wanted.

The best practice is to cut on the machine a die from an intaglio and a type from a relief model. The die is finished and hardened. The type is then easily fitted to the die and hardened. Subsequent dies are cut on the machine and finished with types with the aid of very little bench work. Although a moderate amount of pressing is done in hydraulic or other presses, so little stock is upset that the steel surface is left in its previously homogeneous state.

In the case of the automatic die-sinking machine, as the model is always his guide, much less skill is required on the part of the operator, although at times it is advantageous to manipulate the hand feeds. The machine follows the master whether hand-operated or running automatically.

Thus the great importance of a method which makes of die sinking an ordinary machining operation. A method by which a pattern is automatically copied in the steel block makes production of dies almost as simple a proposition as if it were a question of making a cast die of iron or bronze.

Automatic Die-Sinking Machines

For convenience of description, automatic die-sinking machines may be divided into two classes: reducing and reproducing—on flat or cylindrical surfaces. Though developed for and applied to many diversified uses, they have all in common the feature of normally automatic operation controlled by pattern or guide.

The reducing machine, or reducing lathe as it has sometimes

[1]Gen. Mgr., Keller Mechanical Engraving Co., Mem. Am.Soc.M.E.

Abstract of a paper presented at the Annual Meeting, December 1920, of The American Society of Mechanical Engineers. All papers are subject to revision.

been called, in some form seems to have been the first really automatic machine employed for making dies and molds. In the earlier development these were for a long time confined to coin and medal work and later to such lines as called for work of rather artistic and intricate nature, such as jewelry, silverware and later builders' hardware, etc.

Fig. 3 Machine Work Only, Not Retouched

Fig. 1 shows a small motor-driven reducing machine cutting the die for a medal, and Fig. 2 a large machine of the same type. Both are three-dimension machines in which the tracer follows the details of a large model or pattern to be reproduced in a given smaller size in intaglio or relief.

The lever (or bar) has its fulcrum at one end and is so supported that it has perfect freedom of motion in and out of the various depths of model or pattern and up and down across its face. The third dimension is taken care of through the movement (in this

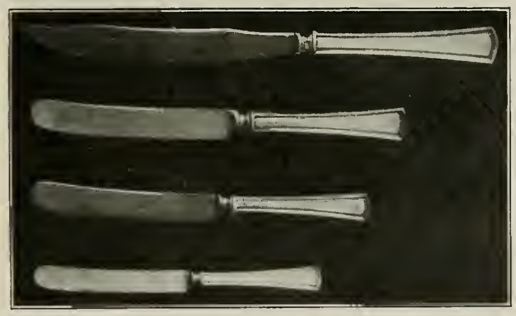

Fig. 4 Work Done on Reducing Machine: A Variety of Sizes Cut From One Large Model

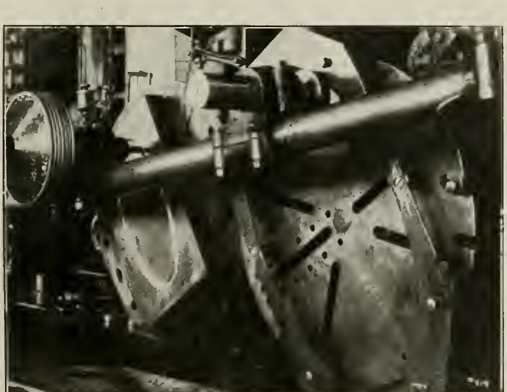

Fig. 5 Reducing Machine Milling an Oval

case rotation) of the pattern and work. These are supported on faceplates carried on spindles and supported in brackets on the bed of the machine. These two spindles are worm-and-gear-driven at the same speed and rotate in the same plane. The worms are carried on a splined wormshaft at the back of the machine.

It will be seen that the work, being located nearer the fulcrum than the model, must necessarily be smaller and in exact ratio as the distance from the center of the work spindle to the fulcrum is to the distance between the model and fulcrum. For convenience in locating the work spindle a scale running from the fulcrum center to the model spindle center is applied to the bed of the machine. As this scale is divided into 1000 equal parts, the use of a very simple formula readily indicates the proper location for the work spindle.

In these machines the model position remains fixed. The work spindle is movable and readily adjusted to any position between fulcrum and model, the point nearest the fulcrum producing the smallest size and the size increasing relatively as the model is approached. The cutter bracket must naturally be adjusted to a point in line with the center of the work spindle.

The free end of the bar is supported on a roller on a screw-controlled saddle at the end of the machine opposite to the fulcrum. With every revolution of the faceplates the cutter bar is moved a predetermined distance. The bar feeds either up or down, depending on the nature of the work. Roller support of the bar helps to keep the friction down to a minimum. A spiral course is traversed by the tracer point and completely covers the surface of the model.

It will here be seen that a speed-controlling device is required so that the tracer may travel over all points of the model at a uniform speed. If the speed selected is correct near the center, it would be too fast at a point on the model further away and the tracer, on account of inertia of the bar, would not reach but would skip the deepest points in the pattern.

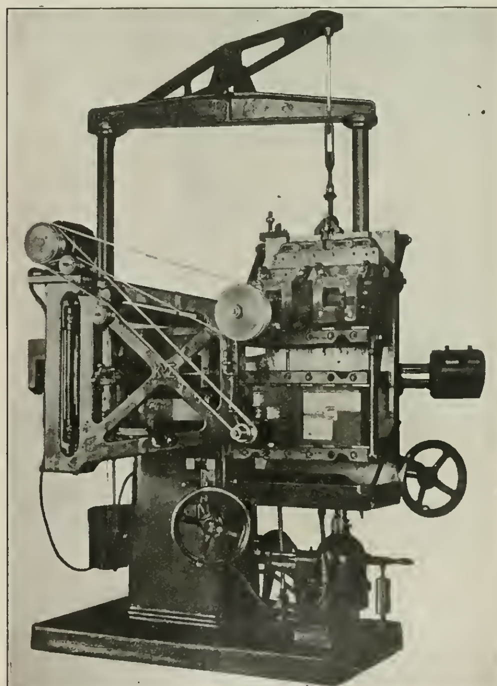

Fig. 6 Sensitive Duplicating Machine Capable of Fairly Heavy and Deep Cutting

The device employed for this purpose is directly connected through gearing to the drive motor and transmits the power to the worm shaft through the friction of two circular disks with cork inserts which are in contact through the action of a spring when the machine runs at the required speed. As soon as there is a tendency to run faster, the friction disks are separated through the action of a ball governor.

For work of a rectangular or elongated outline an oscillating mechanism was found necessary and developed. This is now accomplished either by reversing the drive motor through a reversing switch or by means of a reversing jaw clutch. In either case the control is through two adjustable dogs carried on the gear driving the model spindle.

Figs. 3 and 4 show specimens of work done on reducing machines; those in Fig. 4, illustrating a variety of sizes, are cut from one large model.

Fig. 5 shows a reducing machine cutting an ellipse. The work comes from the machine exactly to size and much better than when done in a lathe with elliptical chucks, with the added advantage that the machine is not confined to geometric figures as any shape can be cut in this way. Boiler plate about $^1/_8$ in. thick is used for templets.

The bar is suspended and so counterbalanced that the roller on the tracer is always bearing upward and in contact with the model. In this case the regular feed is not used. Size is controlled by using an oversized tracer for the first cut.

Duplicating Machines

The duplicating machine is used in all the lines previously noted which do not call for dies with very fine detail or of highly ornamental design, and in which the detail of the model can be reached with a tracer which need not be very sharp at the point.

The models are easier to make than in the case of the reducing machine, and very frequently there is a model already in existence. Old dies are frequently used as models. Where a piece has been broken off, the gap is filled up with brass or solder.

The fields of usefulness for duplicating machines are much the same as for reducing machines. In addition, however, they are now very generally used in the making of metal patterns and core boxes.

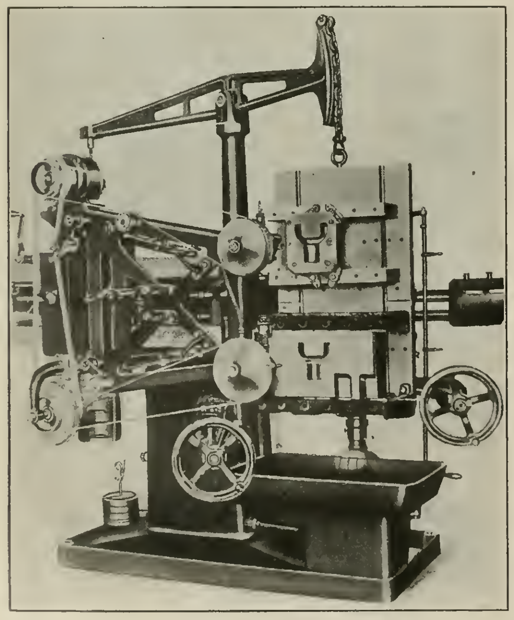

Fig. 7 Heavy Type of Duplicating Machine

Fig. 6 shows a duplicating machine that is quite sensitive and yet capable of fairly heavy and deep cutting. For convenience in counterbalancing the work table travels up and down in a vertical plane, and a saddle supporting a fulcrumed cutter bar moves either right or left at right angles to the plane of travel of the work. The tracer is held in position against the model by means of weights connected to the bar over pulleys.

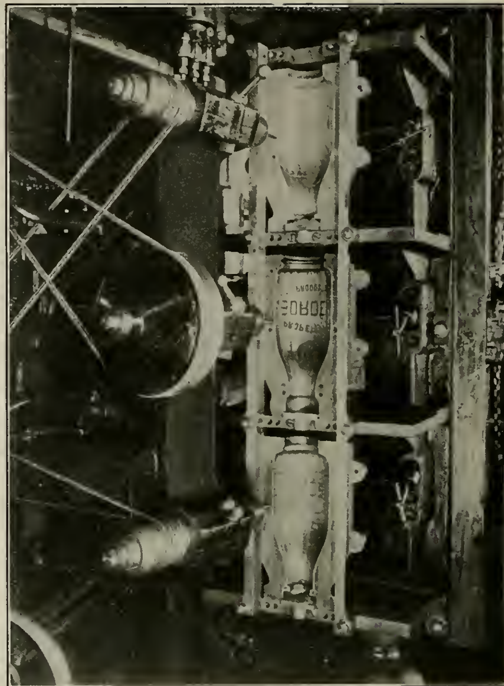

Fig. 8 Portion of Bottle-Mold or Core-Box Machine

Fig. 9 Fixture for Holding Two Dies and Two Models in one Setting

On this type of machine the cutter and tracer points are alike in size.

The design of the cutter bar and its proper support are of great importance—minimum weight, maximum strength, and above all, sensitiveness. For light work, very carefully made roller bearings are used, with a ball bearing to take up the thrust. For heavy work, pivot centers carefully ground and lapped work best.

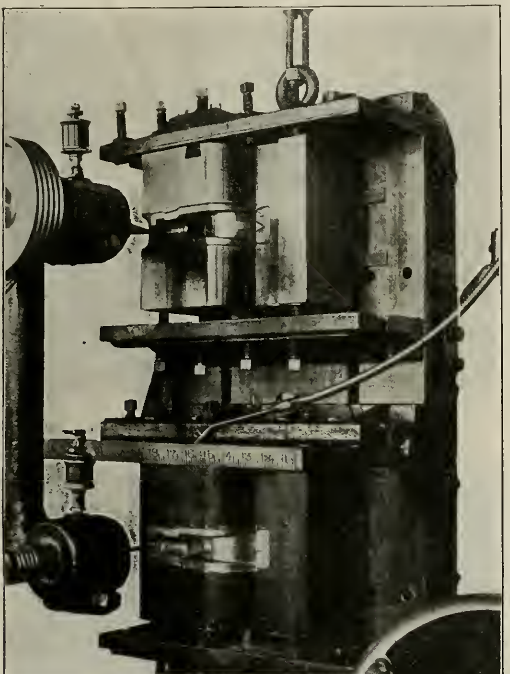

Fig. 10 Using a Die as a Master

It should be noted here that the model and work are carried on *one* rigid member and the cutter and tracer also on *one* member. There is no change in relation between model and work or tracer and cutter; therefore the accuracy of the result.

Fig. 7 shows a machine the same as that of Fig. 6 in principle and general design but heavier. It is really an automatic milling or profiling machine, but when operated by hand it works very much like the well-known hand-operated die-sinking machines, with the great advantage, however, that the operator always has the pattern to follow. For this reason there is less skill required. The hand feed is used principally for hogging out and setting up the work. In every case the pattern is always followed by the tracer.

Thus by this method the greatest difficulties of die sinking have been overcome. Irregular surfaces present no difficulties.

This machine is capable of heavy cutting to practically any depth of a 12-in. die, and it will machine die blocks up to 27 in. by 16 in. face by 12 in. deep. As the machines run automatically a large part of the time, one man can tend a number of them, the operation being quite simple. In many shops they have been operated in shifts for 24 hours a day.

Fig. 8 shows a portion of a bottle-mold or core-box machine which is similar to those just described but has a centrally located model and cuts two pieces of work simultaneously, one above, the other below, the model. It has variable-speed drive motors automatically controlled to take care of the conditions within the cavity calling for a sudden change of speed. The work table swivels automatically so that the feed may start at the surface at one side of a mold with a half-round cavity and finish at the surface at the opposite side, the work table changing its position in relation to the tracer and cutter automatically but very gradually.

These machines work very rapidly as compared with the old hand methods, cutting a pair of bottle molds in from one to six hours, the molds leaving the machine accurately matched and requiring comparatively little hand work. They are equally rapid on metal core boxes.

A fixture for holding two dies and two models in one setting and which facilitates setting up, is shown in Fig. 9. It is especially useful in quantity production in connection with drop-forge die work. All dies of this class have two sets of matched edges, which are planed square to each other. The dies are placed on the fixed lower jaw resting on the matched edges and brought forward until their faces touch the stops. They are also moved endways either to the right or left until the matched edges touch a side stop.

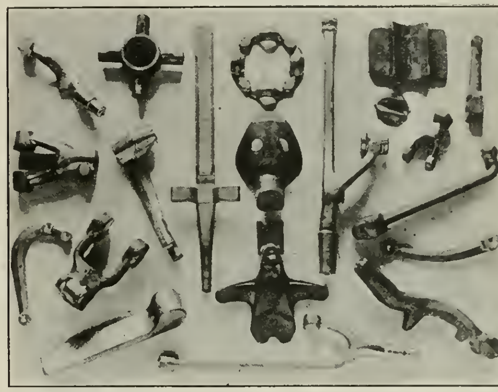

Fig. 11 Forgings Made from Dies Cut in a Duplicating Machine

The models are held in the same way. The setting-up is quickly done and the corresponding cavities match with accuracy.

Most dies cut on a duplicator or automatic die sinker require a moderate amount of hand finishing (scraping, polishing or chasing), depending on the class of work. There are many cases where dies can be put in use as they leave the machine, without any hand finishing (see Fig. 10). This is well illustrated in the sample forgings shown in Fig. 11.

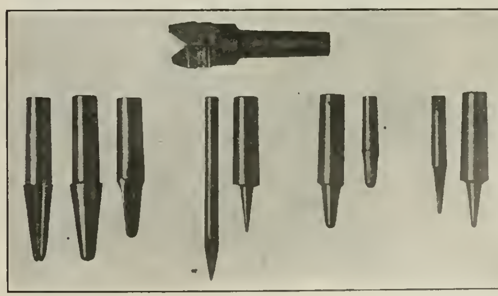

Fig. 12 Cutters, Mills and Tracer Points Used

The cutters used in these machines are quite simple and are of three distinct types as shown in Fig. 12: the diamond point, up to about $^1/_{16}$ in. diameter at the point, made of round stock much like a flat drill; the round-nose fluted end mill, from $^1/_{16}$ in. in diameter at the point up to practically any size and having two or more flutes, depending on the size; and the formed end mill, used occasionally for spotting, or hub cutting as it is sometimes called.

Until recently hard-metal models have been used on the machines to resist the pressure of the tracer point made necessary in order

to keep the cutter in the work. The reduction of this pressure, so that models of cement, plaster, soft metal or other comparatively soft materials may be used, has been accomplished by means of an electrical control of the cutter.

In the electric-control method the cutter bar is positively operated by means of a lead screw, which in turn is under control of the tracer. The tracer is so constructed that the pressure on the master is only a few ounces, thereby permitting the use of the soft masters. But the cutter bar is positively controlled by the lead screw so that the pressure which can be brought to bear on the cutter is limited only by the strength of the cutter and the capacity of the machine. The in-and-out movement of the cutter bar being entirely dependent on, and controlled by, the action of the tracer on the lead screw, also permits the use of straight-flute mills and the cutting of straight-sided cavities.

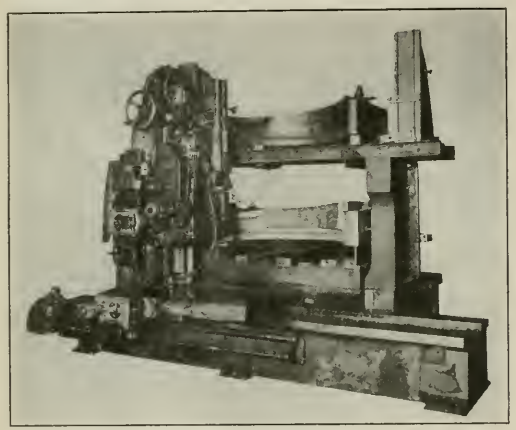

Fig. 13 Machine Capable of Taking Heavy Cuts on Large Dies and Provided with Electrically Controlled Tracer for Use with Models of Wood, Plaster or Other Soft Materials

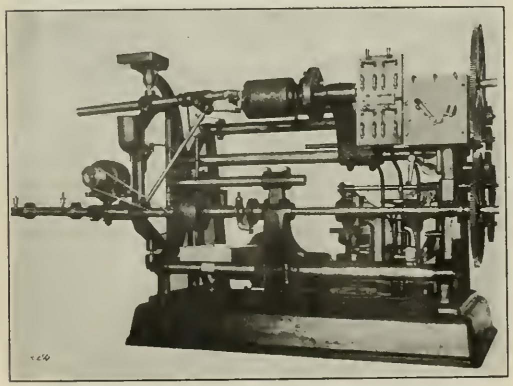

Fig. 14 Roll-Cutting Machine

This method of electrical control has also made possible the construction of much larger machines capable of heavy cuts on large dies.

Fig. 13 shows a machine of this type operating on automobile fender dies. This style of machine is built to cut the largest dies that can be used for auto bodies, fenders, axles, crankshafts, bath tubs, etc.

On account of the weight of the work it is fastened to the machine bed and remains in a fixed position. The head carrying the cutter and tracer travels back and forth in front of the work and model in a horizontal or vertical plane. The tracer and cutter travel in and out, taking care of the depth of die through the action of the electrically controlled tracer.

Advantages and Relative Cost of Machine-Cut Dies

The first question that is usually asked is: What is the percentage of saving as compared with hand work? And the second is: How much hand finishing do machine-cut dies require?

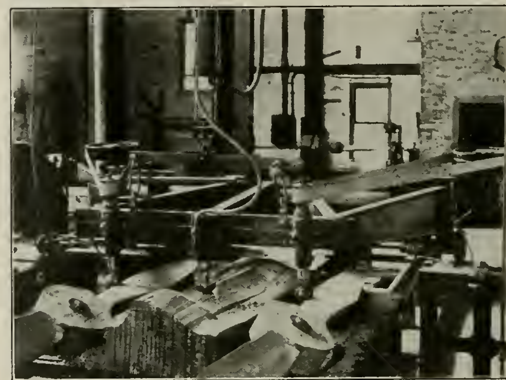

Fig. 15 Propeller-Carving Machine

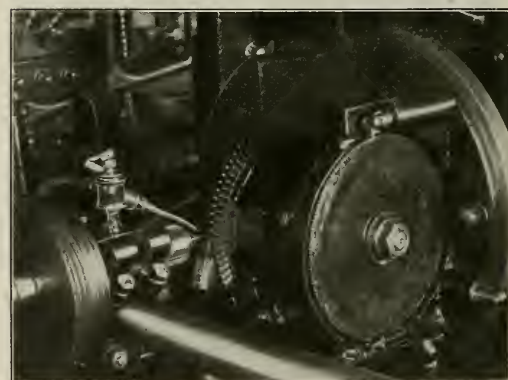

Fig. 16 Machine for Cutting Buckets on Turbine Wheels

The amount saved with the use of automatic die-sinking machines is translated into figures with difficulty on account of the vastly varying conditions. In most cases it is considerable: the more difficult, the greater the saving over hand work. The average is over 50 per cent and in many cases as much as 80 per cent. Some of the other advantages are:

Having dies when required
Speed
Difficult dies no more trouble than simple ones
Reduced overhead
Convenience in replacing broken dies
A small flexible die department, adjustable to slack periods and peak-load requirements
Uniformity of product.

A method which can afford to disregard what would otherwise be considered prohibitive difficulties, permits the manufacturer to design his dies purely from the production point of view, instead of being limited by considerations of die costs.

In connection with a large Government program it was possible to eliminate a restriking and bending operation by making a rather

(Continued on page 606)

Variable-Speed Motors in Finishing Plants

The Saving in Fuel Resulting from Their Substitution for Independent Steam-Engine Drives, as Shown in the Analysis of the Power Problems of a Typical Finishing Plant

By WARREN B. LEWIS,[1] PROVIDENCE, R. I.

THE perfecting of the adjustable-speed, direct-current motor has wrought a revolution in the engineering economics of the cotton-cloth-finishing business far greater than would at first appear to be attributable to any advantage which might be derived from the substitution of electric for mechanical drive. Twenty years ago the stationary, constant-speed electric motor found its application principally in small shops or in departments of larger shops where convenience was the predominating factor. A few years later any proposal to substitute electric drive for mechanical drive met with a demand for proof of greater efficiency in transmission, and several years elapsed before prospective purchasers would admit that the use of electric drives would produce economies outside of the field of simple engineering economics.

The adjustable-speed, direct-current motor opened up a field in which mere mechanical efficiency was not of prime importance, and established a record for productivity that no other variable-speed device could attain. Since that time the adjustable-speed motor has been considered primarily as a variable-speed device which, by reason of its simplicity, perfection of speed control, etc., has outrun all of its competitors. In this paper it is proposed to show that the usually accredited advantages of the adjustable-speed, direct-current motor are not paramount in its selection for driving certain classes of machinery used in the cotton-cloth-finishing business, but that it has made possible a reduction in production costs that are most striking.

Nature of Power Problems in Finishing Plants

In the manufacture of cotton cloth the power problems are of the simplest character. In the finishing business, however, they are most complex. Finishing plants use large quantities of power, heat and water, and so great are these as factors of cost that the very location of a finishing plant is determined by proximity to ponds or streams which will furnish millions of gallons a day of clean water, and adequate facilities for the transportation of fuel, greater in weight than the total weight of the product shipped out.

If one takes occasion to visit the many finishing plants in New England (exclusive of those which have in the last few years rebuilt their power plants in accordance with the most modern ideas—and these are very few in number) he will find a great number of small engines, either belted, geared or otherwise connected to machines which operate throughout a considerable range of speed; and one or more large engines exhausting to the atmosphere or running condensing, driving through the usual line and countershafts machines which operate at constant speed. He will find numerous drying machines using steam at pressures of from 5 to 10 lb., individually driven by the before-mentioned small engines, the exhaust steam from which passes into the machines and furnishes the heat for drying. Small engines driving machines which, in themselves, do not require heat, will probably be exhausting into a main which will be connected also with drying cylinders, furnishing the steam which those cylinders require in excess of that furnished by the engine which drives them. He will notice numerous blower systems furnishing hot air for drying purposes; and in many cases the heating coils of these blower systems will be supplied with live steam. He will notice numerous dye tubs, jigs and vats which are periodically filled and emptied; and which, more often than not, are supplied with cold water which has to be heated to the boiling point with live steam.

If he comments at all upon the use of so many small engines, he is sure to be told that the arrangement is a most economical one, inasmuch as all of the exhaust steam from these engines is used in drying processes, and that nothing is to be gained by substituting some drive which uses less steam per horsepower. Having the engineering mind, however, he will speculate on the heat being discharged from the larger engine, either to the atmosphere or to a condenser, and doubt whether the arrangement is as economical as its owner thinks it is. He will at once realize that the actual brake horsepower required for the entire plant does not balance with the heat being discharged from all of the engines, and that there is very evident room for improvement; and he will arrive at the final conclusion that the small engines are justifiable solely as a means of obtaining varying speeds and not as motive power for producing power as a by-product.

In practically every case a survey of the plant will show that the heat exhausted from the main engines is entirely wasted, except for such as may be used in feedwater heaters. Complete analyses of many of these older plants show that from 3 to 5 lb. of coal are used per pound of cloth finished, which indicates at once the importance of the transportation problem and the extent to which the cost of fuel enters into the total cost of finishing.

As far as electric drives are concerned, the constant-speed machines in a finishing plant may be disposed of briefly, as the problem is very simple and varies only in degree from that which applies to any manufacturing process where the power required to drive the machines should cost a minimum. The same arguments apply, such as lower transmission losses, ability to reduce losses to zero when machines are not in operation, ease of control, cleanliness, etc.

If a perfect balance can be maintained between power requirements and the demands for heat, then there is little more to hope for in that particular direction; or, if in the production of power all of the heat units passing away from the engine can be utilized, then also the desired goal has been reached. Again, if all of the power required can be produced and the heat discharged from the engine be sufficient for process purposes, then the condition is still better because it is always possible to introduce live steam with the least possible loss between the boiler and the point of use. The adjustable-speed motor has not only made this condition possible, but has actually realized it in plants which have become completely electrified.

Motors as Variable-Speed Devices

The adjustable-speed motor is an ideal speed-changing mechanism. The degree of variation which may be obtained is greater than in any mechanical device, the ease with which the variation may be obtained is ideally simple, and the efficiency is high. Consider it not as a motor, replacing some other form of motive power, but as a speed-changing device introduced between a relatively efficient prime mover and the machine to be driven. Originally designed primarily for machine-tool operation, it was designated as a constant-horsepower motor, inasmuch as it was generally operated at high torque when running at low speed and at low torque when operating at the higher speeds. As a matter of fact, at the lower speeds its rating was somewhat decreased owing to the poorer cooling effect with low armature speeds, and the greater heating of the fields with full voltage applied to them. A four-to-one motor, rated at 10 hp. between the speeds of 400 and 1600 r.p.m. would perhaps be better rated at 8 hp. from 400 to 600 r.p.m., and at 10 hp. from 600 to 1600 r.p.m. at the same temperature rise.

As applied to finishing machinery, however, the adjustable-speed motor is more nearly a constant-torque motor. With few exceptions, it is coupled to a machine which requires a fairly definite torque which does not vary. The horsepower developed by the motor therefore varies with the speed; and if the torque was exactly constant, the horsepower would then vary directly with the speed. This means that the motor operates at its rated horsepower at the

---

[1] Consulting Engineer, Mem. Am.Soc.M.E.; President Providence Engineering Society.

Paper presented at the Spring Meeting of the Textile Division of The American Society of Mechanical Engineers, Providence, R. I., April 12, 1921. Slightly abridged.

highest speed, and at a low horsepower at low speeds. This has both advantages and disadvantages. At the low speed the torque being no greater than at high speed, the reduced armature heating offsets to a certain degree the heating in the fields due to the full field current. On the other hand, at high speeds the armature takes maximum current when the field is weak, which magnifies commutating troubles. The commutating and compensated field motor has practically eliminated this trouble, however, so that these motors will develop full horsepower at the maximum speed continuously and give perfect service.

It has been found that in 90 per cent of the cases a two-to-one motor will give all of the speed variation that is necessary for general use; while below the normal speed, lower speeds may be obtained for threading up, cleaning, etc., by the use of armature resistance, which, by reason of the low horsepower used for so small a proportion of the time, does not affect materially the overall economy of the plant. This makes possible the use of a smaller and more efficient motor for the usual working ranges.

Note that the losses in an adjustable-speed motor operating under constant-torque conditions decrease nearly proportionately with the horsepower, and then consider this adjustable-speed motor as a device placed between the machine to be driven and the main power unit which will develop a horsepower on about one-third of the steam required by the small engine. Combine the load of all of the adjustable-speed motors on to one generating unit, and the result will be a fairly uniform load and practically a uniform steam economy in the prime mover. Compare this with the varying load of the individual small engines in which the heat efficiency is constantly varying, and it requires very little imagination to see where we are being led.

Analysis of a Typical Finishing Plant

Applying now the general principles set forth in the foregoing to a concrete case, the author will attempt to analyze a finishing plant having a capacity of about three thousand pieces of finished goods per day, two-thirds of which are printed and the other third finished as plain white goods and dyed goods. This is an assumed plant for several reasons; but the principal one is that it is fairly typical from the engineering standpoint.

For the purposes of this paper the equipment of such a plant may be divided into two groups, namely, machines which operate generally at constant speed, and those which operate at varying speeds. The latter being the most important to consider, may be enumerated as follows:

	Max. Hp. of Unit	Max. Hp. of Equipment
Three singers	6	18
Two mercerizing equipments	25	50

Each of these machines will be driven by variable-speed motive power, i.e., 27 individual steam engines or 27 electric motors, and their total maximum requirements will be, as given in the preceding table, 468 hp. when operating at their maximum speeds.

Under no circumstances will all of these machines be running at maximum speeds simultaneously, and therefore requiring maximum power. Extensive experience with this class of machinery has proved that the load factor, as it might be termed, is about 50 per cent, and that while any one or even a number of machines may be operating at maximum speeds simultaneously, others will either be operating not at all or at low speeds.

The constant-speed machines in this same plant will require 600 i.hp. if the machines are driven from lineshafts, of which about 50 per cent will be friction losses. If driven with individual motors, the load will be about 250 kw. This great difference will not be due entirely to the difference between mechanical and electrical losses of transmission, but in great part to the fact that the constant-speed machines will be operated more or less intermittently.

A condition is assumed here which was almost universal up to the advent of the adjustable-speed motor, namely, that the twenty-seven variable-speed machines are driven with twenty-seven small steam engines and the constant-speed machines driven through line-shafting from a simple non-condensing engine. The boiler plant consists of a number of horizontal return tubular boilers, and the average output is 70,000 lb. of steam per hour, about one-third of which is delivered as live steam to processes where high-pressure steam is used.

Condensation in Steam Piping

There are many hundreds of feet of live- and exhaust-steam pipes around this plant, necessitated by the fact that the small engines and process machinery are widely distributed and steam must be delivered to them and exhaust steam taken away from the former. Numerous charts taken from boiler-feed meters will show that the condensation in the steam-piping system will be 10,000 lb. of steam per hour for every hour that steam is on the system, which may and frequently does mean twenty-four hours a day. No material reduction can be made in this loss, except through the removal of all of the piping that is not actually essential to the driving of the machines.

The substitution of the adjustable-speed motor makes it not only possible to eliminate this part of the piping system, but to reduce the sizes of pipes carrying live steam to processes. It is seldom that live steam at a pressure of over 50 lb. is required in the processes; and therefore, with the elimination of the engines, the drop in pressure between the boilers and the processes can be madd 50 per cent or more. Or, still better, the boilers may be divided into two batteries, one group being operated at 150 lb. or more ane delivering steam to the main unit and boiler-feed pump, while the other group may be operated at pressures of from 80 lb. down. As a considerable variation of pressure in steam for process purposes it is not detrimental, advantage can be taken of the heat stored in the furnaces and in the water within the boilers, so that during periods of heavy drafts the fires will not have to be pushed to maintain steam pressure, while at the slacker periods heat will be stored up.

This has been done in several plants with the result that the evaporation per pound of coal for the group of boilers furnishing live steam for processes has been very much improved. This again, has been possible through the introduction of the adjustable-speed motor in place of the small engine.

The heat distribution under the conditions stated may be shown by diagram as in Fig. 1, in which the area of the circle corresponds to a boiler output of 70,000 lb. of steam per hour at 100 lb. gage pressure, feedwater being taken from any source of supply at an average temperature of 100 deg. fahr. and heated to an average temperature of 170 deg. fahr. The question may immediately arise as to why a temperature of 210 or 212 deg. fahr. is not assumed; and the answer is that in practically none of these older finishing plants is the feedwater even heated to a temperature of 170 deg. fahr. This is probably due to the fact that a heater with sufficient surface to raise the temperature of the entire boiler feed from 100 to 210 deg. fahr. would be very large; and with the usual exercise of false economy, heaters of about one-half of the needed capacity are used.

Referring to Fig. 1, the area of the segment A represents the amount of steam which is condensed in the piping system. This figure is taken from actual boiler-feed charts in four plants of approximately the productive capacity of the one that we are considering. The area B is the amount of steam taken by the main engine and is based on 25 lb. of steam per i.hp-hr. The area C is the steam delivered to the small engines. The area D is the steam used as live steam in the processes. Segment B is divided to show the amount of heat which is recovered in the feedwater and the heat which is lost. Segment C shows that of 23,000 lb. of steam delivered to the small engines, 20 per cent is entirely lost in condensation, while the remainder may be used for drying purposes.

Steam Requirements for Drying

The drying operations in this plant will require that each yard of goods be dried three times and will require $1^1/_2$ lb. of steam per pound of cloth dried. The three thousand pieces will average in weight 10 lb. per piece, and the hourly rate of steam used for drying will be 13,500 lb. From the main engine 10,000 lb. of steam per hour are available, and from the small engine 18,400 lb., a total of 28,400 lb., or more than twice that required. While as a matter of

engine doing the constant-speed work, it is apparent that the most economical type of engine would have been the logical thing to have used.

The diagram as presented represents the best condition in that the driers are operating simultaneously with the engines. As a matter of fact, more often than not some of the driers will not be in operation, having completed their day's work before the end of the working day, or not being in use at all in some of the departments, with the result that the steam exhausted from the small engines will not be reduced in so great a proportion as will the uses of low-pressure steam, and a still greater proportion will be wasted. This is particularly aggravated when the printing department is busy and the dyehouse is not, inasmuch as printing machines always exhaust steam greatly in excess of the requirements in that department.

Segment *D* of Fig. 1 presents possibilities for some use of low-pressure steam, which, however, were seldom taken advantage of in the older plants, and not always in those which have been rejuvenated. In those processes where it is necessary to heat water up to the boiling point, water may be preheated to a temperature of 160 or 170 deg. fahr. and stored in tanks, from which it may be drawn for use in the dyehouse or in the boiling process. That this has not been done more generally is probably due to the fact that the cost of hot-water heating and storage systems is high, and there are difficulties in conveying hot water which are not easily surmounted. It is far better, therefore, to be able to use all of the exhaust steam for direct heating.

This leads up to the general statement that the whole problem of producing power in a finishing plant has been attacked from the wrong end. Analyzed properly, one should first determine the amount of low-pressure steam which can be used economically, and then so design the power plant as to derive all of the power required in the process of producing the low-pressure steam. If it is possible to produce all of the power from the minimum demand of exhaust steam, then the most economical balance will have been attained, because live steam may be introduced through a pressure-reducing valve with practically no loss.

Now for the analysis of this same plant rebuilt in accordance with the statement which has just been made, viz., that the power is to be produced from the steam which can subsequently be passed on to processes with the least loss.

If the plant is to be electrified throughout, the constant-speed motor load will be 250 kw. and the adjustable-speed motor load 210 kw. No attempt will be made to discuss the relative merits of a.c. or d.c. generation, this being determined by individual conditions; but for this particular plant it is assumed that a.c. motors are used for the constant-speed work, a motor-generator set to give 230-volt d.c. current for the adjustable-speed work, and a 500-kva. generator which may be either turbine- or engine-driven.

The drying operations in this plant require 13,500 lb. of steam per hour at about 5 lb. pressure. The steamer can use 1500 lb. of exhaust steam per hour if it is clean. The two soapers will use 100 gal. of water per minute, which in the old plant has been heated to a temperature of about 170 deg. fahr. by introducing live-steam pipes into the soaper boxes, requiring 5000 lb. of steam per hour. This work can be done with clean exhaust steam, or it can be done in part by collecting all of the condensation from drying cylinders and pumping it into the soaper boxes, instead of back to the boiler-feed heater. This is merely a matter of comparative expense and ease of control.

To heat the feedwater to 210 deg. fahr., 3500 lb. of steam per hour will be required, this figure being derived as follows: The live steam for processes has been reduced from the former requirement of 22,000 lb. to 15,500 lb., requiring that water be taken from an original source and which may be assumed to have an average temperature of 60 deg. fahr. The remainder of the steam (which will be shown later to be 26,000 lb.) will be made from feedwater which has been collected from the various driers at a temperature of 160 deg. fahr., and this being clean water, it can be returned to the boilers.

The total low-pressure steam uses, then, are 23,500 lb. per hour, exclusive of the steam required to heat the buildings, which, taken

any effect upon the design of the power plant.

To operate this plant 460 kw. of electric energy and 23,500 lb. of exhaust steam per hour will be required. A simple, non-condensing, Corliss, releasing-gear engine, direct-connected to a 500-kva. generator will, between the limits of one-half and full load, develop a kilowatt with 42 lb. of steam at 150 lb. initial pressure and 5 lb. back pressure. A 500-kva. steam turbine will operate at the same steam economy.

The turbine has the advantage of giving oil-free exhaust steam. With some precautions the simple non-condensing engine can be used, the chief problem being to remove the oil from the exhaust steam, through the use of properly designed separators. If the plant is already equipped with a good economical reciprocating engine, it would be perfectly good engineering to keep it in service.

To supply 460 kw. at 42 lb. of steam per kw. will require 19,320 lb. of steam, and 90 per cent of this can be delivered to apparatus that can use low-pressure steam at 5 lb. pressure. This will provide slightly less than 17,500 lb. of steam, whereas 23,500 lb. are required. This is a condition which should be very much sought for. If a set of drying cans using a large amount of exhaust steam is stopped for a time, whereas the power required to drive them represents, with the electric drive, comparatively little steam,

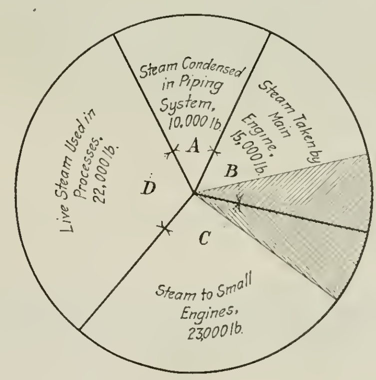

Fig. 1 Heat Distribution in an Engine-Driven Finishing Plant

then there will still be a deficiency of exhaust steam in the whole system, and it is always possible to introduce live steam.

The Coal Saving Effected

In this plant the steam-driven units are confined to one prime mover, and the author would even use a power-driven boiler-feed pump, holding perhaps a steam pump as a reserve unit.

The steam used in this plant, excluding that required for heating buildings, which is a very small amount, totals 43,500 lb.; 23,500 lb. will produce all of the power and low-pressure steam required, 5000 lb. represents condensation, and 15,000 lb. the live steam used direct other than that introduced into the exhaust-steam system. This is a reduction of 26,500 lb. of steam per hour required to operate the plant, and it is easily seen that with an average evaporation of 9 lb. of water per pound of coal over a period of 2700 working hours, this will reduce the coal consumption 4000 tons a year; and this is not the whole of it, by any means.

Reduction of Losses Due to Condensation

Finishing plants do not start up at a specified time in the morning and shut down at a specified time in the afternoon, as do many manufacturing plants. It is the rule rather than the exception that some machines will run overtime, requiring that full steam pressure be maintained on the entire piping system for the benefit perhaps of two or three small engines. It is also the rule rather than the exception that a full steam pressure is maintained on the high-pressure piping system twenty-four hours a day, with the possible exception of Sundays, entailing excessive condensation

losses of more than one-third of the steam which can be accounted for as entering into actual production. With the entire elimination of a large part of the live-pressure steam pipes and a reduction in the sizes of those remaining, not only will the condensation losses be decreased, but it will be possible to shut off the live-steam system entirely when steam at that pressure is not required for high-temperature and boiling operations. Boiling operations carried on at night can be served from a comparatively small live-steam main run directly from the boiler house.

In a certain plant where no printing or dyeing is done, and where the losses through condensation are therefore less than would be found in a plant carrying on all branches of the business, the average boiler load, from 7 o'clock in the morning until 4 o'clock in the afternoon, production being comparatively low, was about 22,000 lb. of steam per hour. For the rest of the twenty-four hours it averaged somewhat more than 8000 lb. per hour. Holiday and Sunday charts in this same plant show about the same amount of water fed to the boilers per hour for the full twenty-four hours. In this case only about one-third of the steam can be accounted for as being directly chargeable to processes.

On another occasion when the plant was somewhat busier, the boiler load was fairly constant at about 30,000 lb. of steam per hour from 7 o'clock in the morning until half past 5 o'clock in the afternoon. From 10 o'clock at night until 6 o'clock in the morning the average rate of feed was 8000 lb. per hour as before.

The maximum boiler load in this particular plant is about 35,000 lb. of steam per hour, so that it is at once apparent that the constant loss of 8000 lb. over twenty-four hours is a very large proportion of the total steam. The remedy for this is to eliminate every foot of pipe which is not absolutely essential and keep steam out of that part of the piping system where it is not needed after the day's work is over.

Influence of Losses on Production Costs

The influence of these constant losses upon the cost of production can be well illustrated by plotting production in yards per week against pounds of coal per yard of cloth finished. Such curves make it at once apparent that as the production increases the amount of coal used per yard decreases at a rapid rate, and probably reaches a minimum when the plant is being pushed to its very limit of capacity. The coal in this case represents nearly the entire mechanical costs, exclusive of repairs, viz., power, heat, light, cost of pumping water, drying and boiling operations, and, in fact, everything which ultimately has to be accounted for in the coal pile. While the adjustable-speed motor can hardly be credited with all of the saving which it has been possible to make in finishing plants, its introduction has made the other things simple of accomplishment. Maximum production on any machine must be the offset to rising labor costs. Finishing machines, operated at varying speeds, are subject to many interruptions, and are started and stopped, or slowed down and speeded up, many times a day. With small engines speeds are rather indeterminate. If a set of driers is slowed down and then speeded up again, there is very little assurance that the speed will be brought back to the maximum permissible at the time, because the eye of the operator is the only speedometer available. With the adjustable-speed motor and its predetermined-speed push-button controller, the running speed is always returned to one definite speed after a slow-down, and a fair degree of assurance is substituted for guesswork.

In some of the processes there are two, and sometimes three, individual machines which have to run in synchronism, the cloth passing through one after the other continuously. With the old mechanical drive the small engine constituted the motive power and the several machines were driven through a series of shafts, bevel gears, pulleys, cone pulleys or Reeves drives, so that the speed could be adjusted to fine limits between the several elements, and then all travel at the same speed.

With the adjustable-speed motor an individual motor can be attached to each element, all operated from one controller, and the speed will be varied uniformly and all elements started and stopped together. This is now the generally accepted method of driving such ranges. If it is desired to operate one element of the range for some particular purpose (as is by no means unusual), then the other motors can be disconnected and the individual machine driven with its own motor.

If the author appears to have been enthusiastic in his presentation of this topic, it is because he has seen the steam consumption of finishing plants reduced to one-half those which previously obtained, and the savings in the cost of fuel pay a very handsome return upon the cost of not only substituting the electric drive but for making all of the other changes in mechanical equipment which could be properly grouped with it.

The Microscopy of Textiles

By FREDERICK J. HOXIE,[1] BOSTON, MASS.

The microscopy of textiles has not been developed to the extent to which its usefulness entitles it. Methods of imbedding, sectioning and staining yarns and cloth must be developed which will hold the material firmly in its original position while the manipulation is being carried on, as the different parts of the textile are in no way connected when sectioned. For example, the sectioning of yarn so as to show not only the relative position of the fibers, but also the location and arrangement of the starch with reference to the fibers. Mounting and photography also present problems requiring special study, with reference to the diffraction of light.

Imbedding. Celluloid solutions are useful for imbedding, but have the disadvantage of requiring complete dehydration of the fibers before they can be successfully applied. This dehydration renders the fibers hard and difficult to cut into thin sections. Paraffin has the disadvantage of being somewhat opaque and showing crystals if it is not removed before the sections are used for photographing. If it is removed, great care must be exercised to keep the fibers and starch in their original positions. Gelatine and glue, which are miscible with water, have useful possibilities, as the water in the colloidal material of textile fibers is essential to their physical and chemical structure and its removal may make important changes in the appearance of this structure with reference to the diffraction of light as well as its behavior with reference to imbedding media. Freezing may be serviceable, but, so far as the author knows, it has not been much used in connection with textiles.

Sectioning. A specially arranged microtome is desirable in order to cut the thin, smooth sections which are necessary for successful photography. Thick sections do not photograph well, as the difference in the refraction of the materials causes a lens action which confuses the detail, particularly in high-power work. Considerable study and experience is necessary in the selection and sharpening of the razors in order to secure good thin sections.

Photographing. As an auxiliary to successful micrographic study, photography is practically necessary as it not only keeps an accurate record of the observations but facilitates comparison of several similarly treated specimens. In order to carry out microphotography successfully, considerable study must be given, not only to common photographic methods such as exposure and development but also to the use of colored light by means of color screens or prisms in order to get the required detail and contrast. In many cases red light, while incapable of giving the fine detail of shorter-wave-length light, has the advantage of giving a stronger contrast which is important in demonstrating surface characteristics of goods or fiber. This applies particularly to photographs of cloth at moderate magnification (less than 100 diameters). Such micrographs are particularly useful in showing defects in weaving and dyeing. In such photographs the angle at which the light is applied is important in bringing up characteristics of the surface of

[1] Engineer and Special Inspector, Assoc. Factory Mutual Insurance Cos., Boston, Mass. Mem. Am.Soc.M.E.

Paper presented at The Spring Meeting of the Textile Division of The American Society of Mechanical Engineers, Providence, R. I., April 12, 1921. Slightly abridged.

cloth, especially when mercerized, the appearance of silk.

With the use of red light it is of course necessary to use panchromatic plates with either special dark-room illumination or no light at all in the dark room.

The arrangement of the camera on the microscope where much high-power work is to be done is of special importance. The author has a camera about twelve feet long with the ground glass in the photographic dark room. Three rods extend from the side of the ground glass to the microscope with handles conveniently located in the dark room. One of these is attached to the fine focusing screw of the microscope, the other two to the mechanical stage so that the specimen can be readily moved back and forward and up and down, the focus being adjusted while the operator remains before the image on the ground glass, which can be comfortably examined and adjusted with external light excluded from the dark room. Up to 1000 diameters photographs can be made with reasonable success with no eyepiece, but the author has recently been making experiments with an eyepiece and magnification up to 4000 diameters. With such high magnification it is

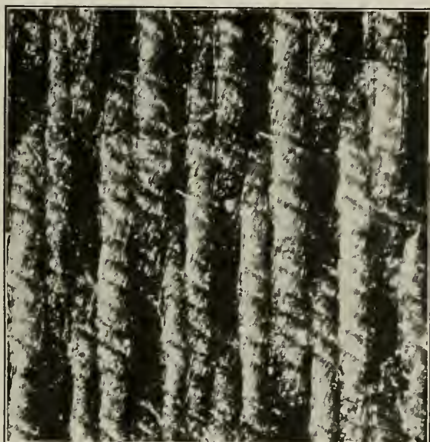

FIG. 1 VENETIANS FINISHED WITH A SCHREINER CALENDER, SHOWING THE DIFFERENT ARRANGEMENT OF THE TEETH WITH REFERENCE TO THE LINES OF THE FIBERS IN ORDER TO GET DIFFERENT FINISHING EFFECTS

difficult to get satisfactory detail, but it may be possible to improve this by using short-wave-length monochromatic light. This, however, makes it difficult to focus the image on the ground glass, as it is difficult to get such light of sufficient brilliancy to clearly impress the eye. A powerful nitrogen tungsten light with condensers makes a convenient illumination.

A useful application of the microscope to the study of cloth is the observation of the effect on the appearance of the goods caused by the uniformity of twist as well as the absolute twist. This is clearly shown by the angle at which the fibers cross the direction of the yarn. This gives a good method of direct measurement of twist if it is not so small as to make the yarn flat and, in this case a fair estimate can be made by making a proper allowance for the flatness.

Very few stains have been studied with reference to textiles. Iodine is commonly used for showing the starch. Polarized light and common textile dyes doubtless have possibilities in studying the inner structure of the fiber. Some common dyes penetrate the fiber only slightly and the yarn scarcely at all, thus causing decided variations in the appearance of the finished goods. This is clearly apparent in photographing dyed yarn sections at high magnifications. Another practical application of the microscope to cloth finishing consists in observing the effect of the angle of the Schreiner teeth on the appearance of the goods and irregular mercerization from various causes, clearly shown in sections.

which are now a matter of mystery can, by photomicrographic records, be brought into the realm of fact, and much of the chance in textile manufacture which has possibilities of expensive misunderstandings can be eliminated.

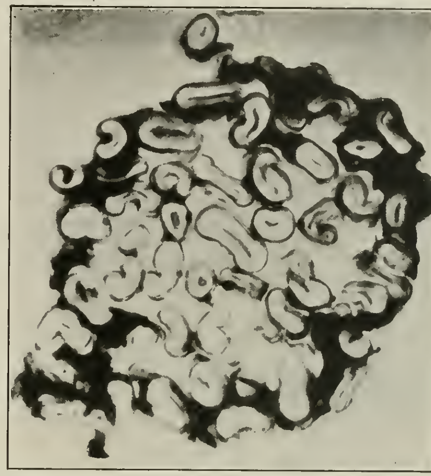

FIG. 2 SECTION OF 120-WARP YARN, SHOWING THE PENETRATION OF STARCH USED FOR SIZING

The general practical value of textile microscopy should cause the technique to grow rapidly and should bring about lively interest

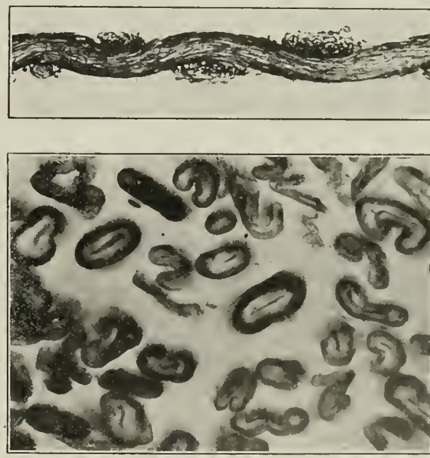

FIG. 3 SECTIONS OF RED COTTON YARN DYED WITH PARA NITRANILINE, SHOWING THE MORE COMPLETELY DYED FIBERS ON THE OUTSIDE OF THE YARN AND THE LESS COMPLETELY DYED FIBERS INSIDE, ALSO VARIATION OF PENETRATION OF DYE IN INDIVIDUAL FIBERS

and profitable discussion which will doubtless center about schools and colleges in which the study of textiles is carried on, and can very properly be developed in the botanical departments of colleges where such departments already exist.

Figs. 1 to 3 give some idea of a few of the possibilities in the application of microscopy to the problems of the textile manufacturer and finisher.

Winding as Related to the Textile Industry

Modern Methods Employed in the Preparation of Filling Yarn and the Saving in Weaving Costs Resulting from Their Employment

By GEO. W. FOSTER,[1] PROVIDENCE, R. I.

OUTSIDE of the electrical field, winding is almost exclusively a textile process of intermediate or preparatory form, and it can be definitely classified as an art of transferring fibrous, thread-like material from a small-capacity container to one of determined form having larger capacity, the fundamental idea of such transfer being to provide long lengths of inspected yarn or thread of other intermediate or final processes, in order to establish a more effective and continuous operation of the same.

The science of winding rests in the principle of ratio between a revolving element, as represented by a package, and a reciprocating element, as represented by a traverse guide, and it is through establishing a correct speed relationship between the two elements that yarn or thread is laid in binding spirals to form a self-sustaining body of material.

While winding was understood in England fifty years ago, yet it could hardly be classified as an art until the year 1890, at which time we started to build winding machinery in this country, and it can be truthfully claimed that real development in the art and its application to the textile industry date from that period, to the credit of American engineering genius and American progressiveness.

Types of Winding Machines

Winding can be classified under two heads, and is represented by two types of machines, one known as the friction or drum-driven (where the package is revolved by surface contact with a cylinder or drum), and the other as positive-driven (where the package is revolved by force applied to its axis). The difference between the two types lies principally in the manner in which the yarn or thread is laid throughout the package, it being obvious that in one case, where the package is frictionally driven, the ratio between the package and the traverse guide is constantly changing, with a resultant change in angle of the thread being laid, while in the other case, where the package is positively driven, the ratio between the package and the guide remains constant, which results in a continuous winding precision of predetermined form.

In the foregoing the author has simply endeavored to outline the art in general. What is of greatest concern is the relation of the art to the industry, and its manifold applications for economic gain.

Winding Yarn for Outside Consumption

Winding machines were first developed for that branch of the industry manufacturing single and plied yarns for outside consumption, and second, for that branch of the industry where the wound product is used as a supply to improve qualities and cheapen costs of subsequent processes within the mill.

Conical packages may be taken as a concrete example with which to illustrate the entire field of winding which applies to that branch of the industry making yarns or threads for outside consumption.

In the early days knitting yarns were spun on mule frames into cop-like form, it being the practice to pack in a case five or six thousand of these small cops for shipment to the hosiery and underwear trade. As a cop weighing only three to four hundred grains was too small and uncertain a supply to use direct, the customer was obliged to rewind the yarn he had purchased on to what was known as a bottle bobbin, in order to get long lengths of material for his knitting machines.

This proved to be a very unsatisfactory and expensive method, for not only did it call for numerous handlings of many small containers, but the very handling and shipping of so delicate a product tended to destroy its form and usefulness. The inevitable result was a considerable loss in valuable time and valuable material, which resulted in friction between manufacturer and consumer, as to which one should stand the loss.

Today the manufacturer takes his yarn from mule or frame direct to a winding machine where the yarn from fifty to a hundred spun cops or bobbins is pieced together to form one continuous inspected thread. The conical package into which this length of thread is formed is then carefully wrapped and sometimes sealed in paper, compactly packed in a case and shipped to the knit-goods manufacturer. The customer opens his case, draws off the paper wrapping, and finds instead of a mutilated cop a perfectly formed supply of great length, which can immediately be utilized for his requirements, there being no waste and no handling process. This amounts to an economic gain; it cannot be otherwise.

For this branch of the industry many various types of winding machines are being made to wind nearly every conceivable kind of material of fibrous or thread-like nature; cotton, worsted, woolen, linen, silk (real and artificial), jute, sisal, hemp, asbestos, paper, braid, tape, and even human hair from China representing some of the materials wound for commercial purposes or outside consumption. The product of the machines that wind these various materials vary from a small quill of fine weaving silk weighing possibly 250 grains, to a parallel-tube package of ½-in.-diameter cord or rope weighing 70 lb.

As the author sees it, the most interesting phase of winding lies in its functional relationship to subsequent processes in yarn and cloth manufacture, or in other words, a direct application of the art for inside absorption rather than outside consumption. The development of winding as an art for this branch of the industry has been no simple matter, but a long up-hill fight, for it has not been a question of meeting outside commercial demands which a mill agent or treasurer can readily understand, but rather a question of coping with inside conditions which are always difficult to change in the face of precedent, practice and self-satisfied management.

One of the greatest engineering problems rests in the ability of our textile engineers to convince mill agents and mill treasurers (particularly the latter) that "there is as much in picking up as there is in digging," and that the longer road to the objective is oftentimes the more attractive and profitable; furthermore, that applying engineering principles to industry for economic gain as well as material profit is much more creditable than gaining these profits through adjustments with labor and strictly commercial activities.

It is not the intention of the author to convey the impression that winding as a preparatory process will effect the millennium in the textile industry, for it is only one issue to the point; however, it has been established that winding processes substantially improve qualities, reduce costs and make jobs attractive for men and women who work and buy.

The three elements in a weaving process are the machine, the material and the human, and it is the coördinate relationship of the three that directly affects production, cost and quality.

In weaving, two elements are embodied, the warp and the filling. Warp yarns formerly were, and now are, prepared in long lengths for weaving, by first spooling, then warping, and finally slashing, thereby presenting to the loom thousands of yards of thoroughly inspected material, representing one of the two elements referred to. The other element—the filling—has only recently been given the same careful preparatory treatment accorded to the warp, the practice in the past having been to perpetrate the error avoided in the warp by injecting into the filling process two or three hundred grains only of uninspected material, which by the law of averages and proportion is negative to the warp element with which it is to be mated.

To offset as far as possible this unequal condition and inconsistent practice, a positive-driven type of winding machine was developed to wind filling with compact precision from mule cops or

[1] Universal Winding Co.

Paper presented at the Spring Meeting of the Textile Division of The American Society of Mechanical Engineers, Providence, R. I., April 12, 1921. Slightly abridged.

frame bobbins on to a paper or wooden container holding two or three times the amount of yarn usually presented to the loom, the process of winding improving the filling, even as the preparatory processes improve the warp, with the result that both material elements are presented to the loom in maximum lengths of equal completeness.

In order that it may be fully appreciated just how this treatment of the filling affects the machine and human factors in the weaving process, and its ultimate effect on the two outstanding economic problems previously referrred to, a comparison of past practices with present methods will be made.

Past Mill Practices and Present Methods Compared

In past mill practice the amount of yarn wound on a mule cop or frame bobbin seldom exceeded 350 grains, and if the mill were weaving 40-in. sheeting, 80 x 80 square, 30s warp, 40s filling, the loom running at 160 picks per minute, the amount of 40s single filling consumed per loom per week would equal 14 lb.

Under these conditions a weaver would be given eight plain looms to run, the total job consuming 112 lb., or 704,000 grains of filling, every 48 hours. Dividing the total grains consumed by the grains wound on one cop or bobbin, proves that the eight looms must stop 2240 times weekly for filling changes, and that the weaver must charge and change shuttles an equal number of times, providing the yarn on every cop or bobbin runs its entire length without breaking. As a matter of fact, the total number of interferences would equal 2400 instead of 2240, due to imperfections in the yarn, sluffing from the containers, and the amount of material usually left on the cop or bobbin butt.

By direct comparison, this mill, winding and preparing its 40s single filling, would present to the loom a bobbin containing 875 grains, or 4200 yd. of inspected material, with a result that the eight looms would only stop 896 times instead of 2400, the weaver charging and changing shuttles 896 times against 2400 in 48 hours, there being no additional interference through imperfections, sluffing, etc. The difference in loom stoppages between the two methods equals 1504 interruptions weekly, amounting to a considerable saving in machine and hand time.

Ordinarily, seven or eight seconds is ample time to charge and change a shuttle with bobbin filling, and 14 to 16 seconds the time to charge and change cop filling; however, this does not hold true if the weaver is occupied mending warp, and it is quite possible for looms to be stopped minutes instead of seconds if the weaver is not in a position to make the filling replacement. In this connection it must be borne in mind that 875 grains of inspected filling will run 22 consecutive minutes in a loom weaving 40-in. goods at 160 picks per minute; consequently, when a weaver is mending warp the remainder of the job is more likely to be running.

If 1504 represents the actual reduction in the filling changes, and eight to sixteen seconds the time lost per change, figures prove that 3 hours out of 48 hours would be saved, as compared with frame-spun filling, and 6 hours as compared with cop filling. While this saving fairly represents the additional time allotment for operatives, it does not represent the complete saving in machine time. For illustration, saving 3 to 6 hours of the operative's time, plus the greater continuity of loom motion, represents the improvement for estimating increased loom efficiency.

Saving in Machine and Operative Time by New Methods

In actual mill practice this saving in machine and operative time results in an increased loom efficiency of 10 to 20 per cent, as compared with frame- or mule-spun filling, which is equvialent to adding that percentage of looms to a mill equipment without initial cost or yearly operating expense.

With long lengths of prepared filling loom jobs are increased from 50 to 100 per cent, depending on the style of goods being woven. On the 80 x 80 style sheeting previously referred to, a weaver running twelve looms would only charge and change shuttles 1344 times weekly, as against 2400 times on eight looms with a 350-grain spun supply.

Under this improved condition, a weaver running twelve looms would only charge and change 36 shuttles per hour, less than 10 per cent of the 60 minutes being occupied in this respect. Furthermore, it has been definitely determined that the higher loom efficiency previously accounted for is not lost when the job is increased in reasonable proportion to the saving in hand time. Increasing a loom job 50 per cent naturally increases operative productivity in like proportion, plus the higher efficiency of each loom, figures and facts proving that the physical burden, or hand time, on the 12-loom job is considerably less than the burden or time on the 8-loom job, where continuous filling changes are constantly interrupting both machine and operative.

In the foregoing the effect of a preparatory process on the machine and operative factors in the weaving process has been discussed and it now remains to show how prepared filling improves quality and saves waste in materials.

As far as improvement in quality is concerned, it is obvious that the fundamental principle in cloth construction calls for the greatest continuity of loom motion that it is possible to establish. Mispicks, thick and thin places, loops and cracks in the selvage are the results of filling changes which interrupt the harmony of loom motion and it follows that any method effecting a 60 per cent reduction in these changes must operate for refinement and quality. Furthermore, slubs, bunches, and soft and thin places in yarn are likely to be woven into the cloth unless removed in a preparatory process.

Filling waste made in weaving is the source of enormous losses in the textile industry, amounting to millions of dollars annually. The author ventures to say that when mule-cop filling is used 8 oz. of waste represents the loss per loom per week, and when frame bobbin filling is used 4 oz. would be a conservative estimate.

Few mill men like to admit their losses in this respect, and it is difficult to convince them that this waste represents a loss considerably in excess of cost value.

During the latter part of the war, when 100s single yarn was selling for $4 per lb., a certain mill weaving average 100s single filling on mule cops was making, according to their waste account, 7 oz. of cop waste per loom per week, and as they operated 4000 looms, the total loss amounted to 87,500 lb. per year. If the cost value of 100s single yarn equaled $2.50 per lb. and the value in cloth equaled $4.20 per lb., this mill lost $218,750.00, plus a possible profit of $148,750.00, totalling $367,500.00; deducting the amount of $10,500.00 received for waste, the net loss, as the author prefers to figure it, was $357,000.00 per year. It is fair to assume, however, that 87,500 lb. of waste cannot be collected and salvaged without considerable expense.

Similar losses, by degree, appear in all weaving processes, and are caused by constant filling changes brought about through short lengths of imperfect and impaired material being injected into the process, and it will be generally agreed that this fairly represents an economic loss.

When filling yarns are wound and prepared for weaving, one-half of one per cent waste is made in the winding process, but no waste whatsoever is made at the loom; consequently valuable materials are woven into cloth for a greater turnover.

When filling yarns are spun for a winding instead of a weaving process, it is usually the practice to spin a greater amount of material on the cop or bobbin by either changing the builder motion on the mule, or by changing the size of ring on the frame. Taking the 40s single filling previously referred to as an example, past practice would spin this count on a $1^3/_8$-in. ring, each bobbin containing 350 grains of material.

The present method would be to spin this number on a $1^5/_8$-in. ring, each bobbin containing 875 grains, or an amount equal to the quantity wound for the shuttle. This equal condition would establish a simple transfer process at the winder, cheapening the cost of that operation. It would also effect a 2 per cent increase in spinning efficiency, due to the reduction in doffing changes, and it follows that bobbin equipment and bobbin transfer changes would be reduced all along the line by the lesser number of containers involved.

As the author sees it, the ideal combination for spinning 30s single warp and 40s single filling for 80 x 80 square cloth, would be to equip all spinning frames with $1^5/_8$-in. rings, warp bobbins and filling wind throughout. This would insure great flexibility of spinning equipment, and as it is claimed, the application of filling wind builders to warp frames would insure a 5 per cent increase in spinning production as compared with past practice.

Under this arrangement bobbins containing approximately 875

grains of warp yarn would be delivered to the spooler, there to be inspected, pieced in long lengths and wound for the warping process. (Incidentally, production at the spooler would be increased at least 25 per cent by the overend delivery from filling wind warp bobbins.)

At the same time, bobbins containing 875 grains of filling yarn would be delivered to the filling winder, there to be inspected, pieced in long lengths and compactly wound for the shuttle. Under these conditions, and only so, can warp and filling yarn be truly mated in a weaving process.

Application of Principle of Preparation to Automatic Weaving

While the author has so far applied the principle of preparation to plain loom weaving, it is not be to inferred that the proposition has less value for looms where the filling is automatically supplied.

Applying a similar treatment to the filling process in automatic weaving, it is interesting to estimate that a weaver running 16 looms with a 350-grain spun supply, must magazine weekly 4800 containers, the automatic features being obliged to function an equal number of times in the transfer of these bobbins from magazine to shuttle. By direct comparison, with 875 grains of wound inspected filling on a bobbin, a weaver would only magazine 1800 containers per week on the 16-loom job.

It is interesting to estimate that if 875 grains of 40s single filling runs 22 consecutive minutes in a loom, a magazine of 24 bobbins would constitute a day's supply. It is obvious that the amount of "feeler" waste made in a week would be reduced in proportion to the difference in bobbin changes; consequently the expense of reclaiming the waste from the bobbins would be lessened in like degree

Bobbin equipment and bobbin replacement expense would be greatly reduced when one bobbin contained 875 instead of 350 grains of material.

It is not contended that rewound filling would effect any appreciable increase in automatic loom efficiency as compared with frame-spun filling; there would, however, be a considerable saving in the hand time, which could be utilized for increasing operative productivity.

As compared with mule-spun filling, it is contended that a preparatory process for automatic-loom weaving will effect all the advantages heretofore outlined in the foregoing plain-loom analysis. Fixing charges and repair expenses on looms, either plain or automatic, are bound to be lowered through a 60 per cent reduction in shuttle or bobbin changes.

A recent application of the preparatory process to worsted weaving brought out some very interesting facts. High-grade worsted serges are usually woven on 3 & 1 box looms, it being the practice to constantly mix the filling by changing the shuttle every other pick, in order to prevent a wavy appearance in the fabric, due to slight variations in the filling yarns. Until recently the practice has been to place in each of the three shuttles a spun bobbin containing approximately 400 grains of filling, totaling 1200 grains in the three shuttles. As the looms were wide and the filling rather coarse, interruptions for filling changes were numerous; consequently, a weaver could only run two looms, while the efficiency of the looms seldom exceeded 80 per cent.

When this proposition was taken hold of, it was found that the same shuttles would easily accommodate a wound bobbin containing 1200 instead of 400 grains of filling (providing this amount of material was compactly wound); consequently, each loom is supplied with 3600 grains, over half a pound of filling yarn in one charging operation, with the result that a weaver now operates six looms instead of two at an efficiency of 95 per cent instead of 80 per cent. The whole situation is pregnant with interesting details.

No figures have been submitted as regards the cost of filling preparation, neither have any of the enumerated savings been reduced to dollars and cents; for in view of the fact that many mills have adopted the preparatory process outlined, and the fact that the method calls for so many readjustments all along the line, the author questioned the advisability of including in this paper any values of a definite nature. He would say, however, that the cost of filling preparation, like the cost of warp preparation, is more than absorbed by the economies superinduced through its use.

In conclusion, he would emphasize the fact that serious competitive conditions will have to be met from many quarters unless the restrictive rules of working, which necessarily limit output, are neutralized by the adoption of such legitimate aid as may be secured in producing quality and volume.

Utilization of Low-Grade Cotton and Staple Waste

By ELWIN HOLBROOK ROONEY,[1] PROVIDENCE, R. I.

In an average American cotton crop 50 per cent will be low middling to strict middling, about 15 per cent better than strict middling, while 35 per cent will be below low middling. About one-half of this low-grade cotton is unspinnable unless it can be cleaned. The other half, although spinnable, has been considered so unprofitable due to the loss in waste, the low efficiency of production, and the character of the finished product that it has been thought better to purchase a higher grade of raw material.

The total annual production of this low-grade cotton amounts to three to four million bales. In addition to this there are one-half to three-quarters of a million bales of staple waste. By proper utilization of this low-grade cotton and waste we could increase our supply for standard goods, such as osnaburgs, prints, heavy ducks, carpet warps, twines, etc. by about 20 per cent, or enough to supply more than five million spindles.

There is no excuse for a mill to class its card strips and comber noil as waste, because this waste, so-called, can be cleaned by machinery which separates the cotton from foreign matter, reclaims the stronger fiber, and raises the grade up to that of the original bale. If this reclaimed waste is properly mixed with cotton in a Butler mixer, it cannot be detected in numbers up to and including 40s count. This saving may equal $7^1/_2$ to 10 per cent of the total investment.

The utilization of the low-grade cotton is of considerable financial advantage, as one cent saved on the purchase price is equivalent to $2^1/_2$ per cent of the investment in the spinning plant, based on the prewar cost of about $25 per spindle. Some plants in 1920 made profits from 5 to $7^1/_2$ cents per lb. by cleaning this cotton.

The problem of using this low-grade cotton and staple waste is divided into two parts; first, that of properly cleaning it, and second, of mixing it. If improperly cleaned and poorly mixed, it will spin very badly, and the production will be low. However, machinery is being built today in this country which can properly clean and reclaim any low-grade or staple waste made from cotton above ordinary grade.

Today there are several theories in vogue with reference to cleaning cotton. One is that of trying to develop a modified air blast in combination with Crighton openers, automatic feeders, condensers and trunk systems. Another is known as the reginning process, and still another the Gordon cleaning system. Beating may weaken the fiber, but there is no danger of this in blowing. However, it is impossible to clean cotton with air blasts, and the author believes it must be done by machine. If this is so, a card licker-in or comber half-lap injures the fiber less than any other method and has been used more widely and successfully in cleaning cotton than any other. It is the only one which has been successful in separating foreign matter, such as leaf, mote, etc., from the fiber.

There is a great deal of low-grade cotton in ordinary grades running down into what is known as type cotton, storm cotton, bollies, gin cuts, reds, blues, etc. Much of this cotton is strong in

Water Treatment for Boilers

Various Methods of Water Softening—Treatment for Excessive Concentration of Soluble Salts in the Boiler—Corrosion of Boilers and Economizers Due to Decomposition of Organic Compounds at the High Temperatures Accompanying Present Steam Pressures and Superheats, etc.

By JULIAN S. SIMSOHN,[1] PHILADELPHIA, PA.

THE subject of water has been generally regarded in the past as a problem for the chemist, so that the difficulties in its use for boiler purposes have hitherto been passed to him, and, based on his analyses and recommendations, chemicals are added in an effort to prevent scale and corrosion, with more or less success.

There were engineering features, however, that should have been considered—questions of boiler circulation, variations in operating conditions, temperatures and boiler pressure—and it was the realization that all these are necessary in the consideration of water for boilers that has placed the problem outside the realm of the chemical laboratory and over into the field of the chemical engineer.

Since the earliest history of boilers, scale formation has always been a source of difficulty and waste, but with low ratings the scale accumulation was quite limited, and that which did form was largely of a porous nature and quite easily removed. Its insulation value made its appearance felt on the coal pile, but the low cost of fuel up to comparatively recent years gave rise to the attitude that the scale situation was not of major importance in power-plant practice.

Modern operating conditions, however, have created new considerations, and high overrating of boilers and intense furnace temperatures, together with the high cost of fuel, have placed water among the important factors in the economical operation of the power plant.

Composition and Properties of Water

From the chemical standpoint water is a colorless, tasteless liquid which is a compound of two parts hydrogen and one part of oxygen, by volume. The nearest approach to it in nature is in the form of rain, which is the condensation of vaporous clouds. As it falls from the clouds as rain it dissolves the atmospheric gases, oxygen and carbonic acid, and, gathering itself together in streams and rivers, it makes manifest its great erosive powers and solvent qualities. It is this rain water with approximately 15 cc. of carbonic acid and 30 cc. of oxygen per gallon that is slowly dissolving away the bedrock of the Schuylkill River, and in such quantities that in the 150 million gallons of Schuylkill water which Philadelphia uses daily, there are more than 50 tons of this rock invisibly moving through the city mains, with a proportion for each boiler. A typical analysis of filtered Schuylkill River water is as follows:

	Parts per Million
Magnesium carbonate	23.0
Calcium carbonate	1.0
Calcium sulphate	66.5
Silica	6.4
Iron oxide and alumina	2.0
Incrusting Solids	98.9
Sodium sulphate	9.8
Sodium chloride	8.2
Organic and volatile matter	5.1
Non-incrusting Solids	23.1
Total Solids	122.0

The mud in the raw river water has been removed by filtration so that suspended solids are not shown in this analysis. The temporary hardness, namely, the carbonates of magnesium and calcium, is represented by only 24 parts per million, while the permanent hardness, namely, the calcium sulphate, is present in much larger quantities. It is important to realize that in most filtration plants alum or aluminum sulphate is utilized in flocculating and coagulating the finely divided particles of mud. While this naturally improves the physical characteristics of the water and permits the tap supply to be clear and colorless, it nevertheless has a very marked effect on the water for boiler use.

Aluminum sulphate itself is a soluble salt and its efficacy as a coagulant depends upon its conversion to aluminum hydrate, the flocculent precipitate, in the following manner:

$$Al_2(SO_4)_3 + 3Ca(HCO_3)_2 = 2Al(OH)_3 + 3CaSO_4 + 6CO_2$$

Therefore, if an analysis of unfiltered river water be compared with an analysis of the same water after it has passed through an alum filter, it will be seen that, though the total hardness remains the same, the permanent hardness will be greater in the filtered water and the temporary hardness will be correspondingly reduced.

The Removal of Temporary Hardness

Temporary hardness can be largely reduced by boiling the water for a few minutes, which will render it more or less opaque; on cooling, a white precipitate will be formed, consisting of a mixture of carbonates of magnesium and lime almost insoluble in hot water. Permanent hardness (sulphate of calcium), however, is unaffected by heat and forms a dense, hard scale difficult to remove.

Therefore, the larger the amounts of alum added at the filtration plant, the more complex becomes the feedwater problem. It is far preferable for plants operating on river fronts to filter their own supply than to introduce into their boilers water with high permanent hardness with its increased scale-forming qualities and correspondingly high cost of chemical treatment. Well waters are usually harder than river waters.

It is not always practical or feasible to depend upon a feedwater heater for the removal of temporary hardness, for the same effect can be obtained chemically by the addition of either caustic lime or soda, which absorb CO_2 as shown by the following formulas:

$$Ca(HCO_3)_2 + Ca(OH)_2 = 2CaCO_3 + 2H_2O$$
$$Ca(HCO_3)_2 + 2NaOH = CaCO_3 + Na_2CO_3 + 2H_2O$$

Neither heat nor caustics, however, have any effect on the sulphate or permanent hardness, and the precipitant for the sulphates of lime and magnesia is soda ash, or sodium carbonate.

Various Methods of Water Softening

The oldest form of water softening, i.e., the Clark soda-lime process, depends upon the removal of the temporary hardness by means of lime in accordance with the reactions already discussed and the removal of the sulphates in accordance with the following formula:

$$CaSO_4 + Na_2CO_3 = CaCO_3 + Na_2SO_4$$

The outgrowth of this principle is the modern chemical water softener, which is nothing other than an external settling tank with such mechanical improvements as to permit suitable means of mixing the chemicals and facilitating sedimentation.

In certain cases the discontinuous principle is used, in which the water is permitted to react with the chemical by standing until the reaction is completed. The precipitated lime and magnesium are allowed to settle and the supernatant softened water drawn off. In other cases the continuous principle is used, where the water and chemical enter at one point and the precipitation takes place along the path of the water.

The completion of any chemical reaction depends upon two factors: temperature and excess of the precipitating agent. In other words, 10 per cent excess soda ash will soften the water much more rapidly than a 5 per cent excess. Further, with any definite amount of soda ash the reaction will be much more complete at 200 deg. fahr. than at 60 deg. in the same length of time. We may expect to find the use of heat, particularly when exhaust steam is available, of decided advantage in water softening (see solubility curves, Fig. 1).

[1] Consulting Chemical Engineer.

Presented at a meeting of the Philadelphia Section of The American Society of Mechanical Engineers, January 25, 1921. Slightly abridged.

If, therefore, at 200 deg. satisfactory results can be produced with less excess of soda ash, the hot process is advantageous in not only cutting down cost of chemicals used, but also in preventing a more rapid excessive boiler concentration. In very hard waters with, say, 10 grains of lime per gallon and upward, an external treatment is always advisable, but there are many cases where chemicals could be introduced directly into the feedwater heater or the suction of the pump and produce very excellent results with practically no cost for installation. For example, the Delaware River water with about 3 or 4 grains of lime per gallon does not offer much field for the external water softener, which under the best circumstances could only remove about half of the hardness.

Here is the history of boiler cleaning on a 700-hp. boiler at the power station of one of Philadelphia's public utilities:

Aug. 10, 1914	bored 14 rows—entire boiler for inspection
Sept. 23, 1914	bored 2 bottom rows
Dec. 19, 1914	bored 2 bottom rows
Jan. 31, 1915	bored 2 bottom rows
Mar. 12, 1915	bored 2 bottom rows
Apr. 18, 1915	bored 2 bottom rows
May 23, 1915	bored 2 bottom rows
June 30, 1915	bored 2 bottom rows

Aug. 30, 1915, finished boring 336 tubes and 24 nipples. Time consumed, 176 hr.; weight of scale taken out of boiler, 708 lb.

Personal follow-up treatment of boiler feedwater began March, 1, 1916. No mechanical softener was used and chemicals were fed by gravity into the feedwater heater.

Sept. 9, 1916, finished boring 336 tubes and 24 nipples. Time consumed 143 hr.; weight of scale taken from boiler, 258 lb.

Sept. 20, 1917, finished boring 336 tubes and 24 nipples. Time consumed, 21 hr.; scale removed, 92 lb.

Oct. 14, 1918, boiler inspected by Hartford inspector and found in good condition. No tubes bored in 1918.

Oct. 30, 1919, boiler inspected by Hartford Inspector and found in good condition. No tubes bored in 1919.

Oct. 25, 1920, boiler inspected by Hartford Inspector and found in good condition. No tubes bored in 1920.

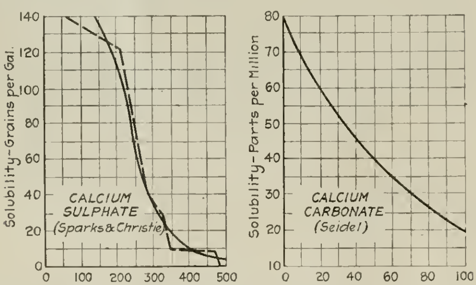

Fig. 1 Temperature-Solubility Curves for Calcium Sulphate and Calcium Carbonate

Prior to March 1, 1916, besides boring the entire boiler annually the two bottom rows were turbined at intervals of approximately six weeks, in spite of the fact that excessive amounts of caustic and soda ash were being used.

Since March 1916, by the use of proper precipitating agents and by varying both the quantity and quality of chemicals to meet variations in the analysis of the raw water, the percentage of returns and other operating conditions, the record has been one of constant improvement with no turbining during the last three years. Such results can only be obtained with the complete coöperation of the chief engineer and a strict adherence to the formulas prescribed and the blowdowns and refills advised.

The so-called "exchange" principle of water softening is based upon a remarkable discovery by Dr. Rudolph Gans, who found that when hard waters are passed through zeolites they are changed in character and become softened. These zeolites are sodium-aluminum silicates and are found in nature as such and can be closely imitated by synthetic compounds. A number of these artificial substitutes are claimed to be superior to the natural zeolites, but this is still a matter of dispute.

All, however, operate on the same general principle, namely, the exchange of lime and magnesia salts for sodium. The magnesia and lime sulphates are converted by this method into sodium sulphate as in the Clark process, but the temporary hardness or bicarbonates of lime and magnesia become sodium bicarbonate. This conversion, while completely eliminating all hardness to the zero point, is of extreme importance in boiler operation, since a certain amount of the carbonic acid from sodium bicarbonate is eliminated by the heat of the boiler and the remaining sodium carbonate concentrates by evaporation.

In waters of high temporary hardness it is necessary to remove a considerable portion of this temporary hardness by preliminary treatment with lime, which makes the process then a combination of the Clark and zeolite processes.

Another absolute method for scale prevention depends upon the process of distillation. It is carried out in the multiple-effect evaporator, making use of the familiar principle of conserving the latent heat of steam and utilizing the steam from the first effect to boil the water in the second. This method has found considerable use in plants where the make-up water is very small and where the elements of expense need not be considered.

In all these cases, however, expense, either of installation of operation, must not be permitted to be the governing factor in the selection of suitable water-softening methods, and the fact that a zeolite softener might be satisfactory and advisable when operating on Delaware River water, is no indication that it should be applied in the treatment of the boiler condition where Schuylkill water is the source of supply.

The complications which arise in the solution of the water problem and the variations which occur in the operation of any plant make it evident how hopeless are boiler compounds in solving the difficulty. The patent-medicine principle is just as incorrect when applied to boiler feedwaters as it is in the healing of human ailments. Many materials used in these boiler compounds are harmful and injurious to the metal and some often guaranteed innocently by their manufacturers to be without effect on boiler metal, do in certain plants where operating pressures are high, corrode the metal and produce serious after-effects.

Deposits on the Boiler Surfaces and Concentration of Soluble Salts

Carbonate of lime when precipitated under atmospheric conditions by heat or by chemical precipitants is a white amorphous precipitate. On standing it becomes crystalline in form, much the same as the mineral calcite, and in the boiler it becomes denser and forms a sludge. Part of the precipitation, however, apparently comes down in the nature of the crystalline form of the mineral aragonite, in which form it is represented in a carbonate of lime boiler scale.

The sulphate of lime becomes a hard, solid, compact and non-porous scale and is usually mixed with variable proportions of the carbonate. Most magnesia salts are finally converted by boiler temperatures into the hydroxide, which then floats to the top together with the carbonate of lime and is carried up with the steam into the steam pipes, engines and turbines. The soluble magnesia content of water is particularly hard to remove since it reacts more slowly with the usual precipitants.

This partially explains why the *percentage* of magnesia in the treated water is a greater *percentage* of the total hardness than in the untreated.

It is useless to attempt to make any statement as to the insulating value of scale in terms of its thickness, and the percentages of fuel losses as indicated in most charts of this character are likely to be exaggerated. It can be stated, however, that hard sulphate scales offer considerably more resistance to heat transference than a carbonate formation. Since, however, the average run of scale represents a mixture of sulphates and carbonates in varying proportions, there can be no definite figure placed on its insulation value.

The soluble salts in the boilers are those which are not precipitated by boiling, and are represented by chlorides and nitrates of lime, together with the sulphates, chlorides and nitrates of magnesia and sodium. Many of these salts are far more soluble in cold water than in hot, and since they are not volatile and do not pass over with the steam, their concentration in the boilers is worthy of attention.

Treatment for Excessive Concentration

It is an easy matter to figure from the analysis of the feedwater and the number of pounds of evaporation just what concentration is reached at the end of any particular time. It is impossible to fix any definite limits as to just where the danger point lies since there are so many factors to be considered, but the consensus of scientific opinion is to the effect that with a 200-lb. working pressure there is no danger of deposition of sodium sulphate or chloride if the concentration is kept below 1000 grains per gallon.

The effective treatment for excessive concentration is blowdowns or the emptying and refilling of boiler with fresh water. Under all circumstances, however, intelligent use of blowdowns can be made to mean much in the saving of hot water, since the heat units with the present price of coal are worthy of every effort of saving.

A fairly accurate idea of the concentration may be obtained if an analysis of the raw water is at hand by knowing the evaporation per hour in gallons, the contents of the boiler, and the number of steaming hours. The author has in many instances checked up the analysis of salts in boilers with the theoretically calculated amounts and found the former figures to differ but slightly from the theoretical.

Corrosion of Boilers and Economizers

While the actions thus far considered deal with the deposition of soluble and suspended solids in the boiler, there is another action which may proceed alone or simultaneously, namely, corrosion. As noted earlier in the paper, there is usually present in water either free or half-bound carbonic acid or both, as well as soluble salts, which under the influence of boiler temperatures decompose, producing acids. Such acids, of course, attack boiler metal and corrode it, sometimes uniformly and sometimes locally in the form of pitting.

All organic matter decomposes under boiler temperatures through a series of stages, from the complex molecules until it approaches the simplest, namely, carbonic acid. The speed with which this reaction takes place and the completeness of the conversion naturally depend upon the variables of temperature, rating, boiler circulation, and other salts that are present. This carbonic or weak-acid corrosion usually takes place in economizer tubes, feed lines and economizer drums. The condensate of exhaust steam is always slightly acid on account of the free carbonic acid which is passed over from the boilers together with the oxygen and sometimes other volatile acids. Economizers and the slower-circulating elements of boilers soon become coated with a red deposit or show signs of the formation of rust cones and pitted metal. These cones consist of a black iron oxide center surrounded by a yellow hydrate in a higher state of oxidation. The red deposit is almost entirely hydrated ferric oxide. This type of pitting is very easy to recognize by its barnacle-like formation (see Fig. 2).

Corrosion once started is difficult to arrest, as the action apparently continues for a long time after the carbonic acid has been removed, and it takes considerable alkali to prevent the extension of corrosion when once it has started. The simplest form of relief is the addition of caustic soda to a point where all the free carbonic acid has been neutralized, and the excessive amounts of soda can be regulated by blowdowns.

Another form of corrosion which affects directly the tubes and drums of the boilers is caused by the accumulation of certain salts, more particularly calcium nitrate, calcium chloride, magnesium chloride and magnesium nitrate:

$$\begin{aligned} Ca(NO_3)_2 + H_2O &= CaO + 2HNO_3 \\ MgCl_2 + H_2O &= MgO + 2HCl \\ Fe + 2HCl &= FeCl_2 + H_2 \\ FeCl_2 + MgO &= MgCl_2 + FeO \end{aligned}$$

Such waters in boilers become slightly alkaline on concentration and react pink to phenolphthalein. This is very misleading to the layman, who does not realize that while the boiler may actually be alkaline, there is a corrosive condition existing. This is more true of nitrate of lime, which on concentration shows decidedly alkaline, as compared with nitrate of magnesium, the reaction of which is almost neutral.

Corrosion Due to Decomposition of Organic Compounds in High-Temperature Boiler Reactions

With high steam pressures and high superheats now in extensive use, cast-iron economizers are no longer considered safe, and when steel economizers are employed the corrosion is often accelerated. To relieve this condition there is now being marketed an air-separation process for the removal of dissolved gases, including the objectionable oxygen and carbonic acid. If the hypothesis be true that corrosion is the effect of the hydrogen ion on the iron metal and that the oxygen dissolved in the water reacts upon the nascent hydrogen liberated, then the removal of these objectionable gases should solve the difficulty. The advocates of this process recommend that it be used in preference to distillation, but in this case, of course, the hardness of the water would still have to be dealt with by the addition of chemicals. Furthermore, the author has seen waters apparently free from both free and half-bound

Fig. 2 Barnacle-like Formation Due to Corrosion Taking Place in the Tubes and Headers of a B. & W. Boiler Used as an Economizer

carbonic acid which produce CO_2 from the disintegration of organic compounds in high-temperature boiler reactions. In most cases, however, if the temperature of the feedwater is held at about 200 deg. fahr., the dissolved gases are driven off sufficiently to make it possible to treat the corrosive properties chemically.

It is apparent from what has gone before that the correct condition for water in a boiler is an alkaline reaction toward both phenolphthalein and methyl orange. The question as to the concentration of soda ash under the influence of boiler pressure and the degree of alkalinity maintained has created a field for most attractive research. As already stated, water softened by zeolites almost invariably contains free sodium carbonate; also water from all softening systems contains sodium carbonate, and by the constant evaporation of water it is an easy matter to figure theoretically and practically the number of grains per gallon present at the end of any definite period. In the fall of 1915 the author was called upon to treat water in four boilers in a textile mill near Wayne Junction. These boilers were of the return tubular type, approximately 150 hp. each, and the supply was a mixture of Schuylkill River water furnished by the city and varying amounts of well water of about 9 grains per gallon hardness. The feedwater heater

was of the closed type and the small amount of temporary hardness present was practically entirely eliminated before entering the boilers. The particular treatment called for no caustic soda but considerable amounts of soda ash and phosphates as lime precipitants. The boilers operated at about 110 lb. pressure and to the author's surprise an examination of the water at the end of two weeks' operation showed the presence of free caustic soda.

It is general knowledge that at red heat sodium carbonate in the presence of a current of superheated steam is converted into caustic, and assuming this to be 1500 deg. fahr., it is a temperature evidently greatly in excess of any temperatures in an operating boiler. Nevertheless, from work done at this and other plants, it has become evident that with the rise of temperatures as produced by increasing boiler pressures, increasing amounts of sodium carbonate are converted into caustic soda with free carbonic acid, and in the case of condensing units this would be returned again and again to the boilers.

On the assumption that carbonic acid would be found in the condensate water, an analysis would show at about 60 deg. fahr. approximately 4500 cc. of gas per gallon of condensate, whereas the author's experience in numerous samples has ranged from 50 to 95 cc. as a high figure. The thought suggests itself that perhaps the gas had been removed with the air from the air-pump discharge, but since dissolved carbonic acid is not readily liberated until its saturation point, and further, since condensate water is always saturated with oxygen, that cannot be the case.

Of the two possible combinations of carbon with oxygen, CO_2 and CO, the former combines with alkalis to form carbonates and the latter to form formates, and just as red ferric oxide can be reduced to black ferrous oxide, so carbon dioxide can be reduced to carbon monoxide and its salts from carbonates to formates. These combinations may be represented by the following equations:

$$Na_2CO_3 + H_2O = \underset{\text{(sodium formate)}}{NaCHO_2} + NaOH + O$$

$$2NaCHO_2 + H_2O = \underset{\text{(sodium acetate)}}{NaC_2H_3O_2} + NaOH + O$$

$$NaC_2H_3O_2 + NaCHO_2 = \underset{\text{(acetaldehyde)}}{C_2H_4O} + Na_2CO_3$$

In the presence of formate of soda the purple color of permanganate might be expected to be destroyed if added to a sample of boiling water, and by actual test that is exactly what happens.

Soda ash or sodium carbonate, which are not oxidizing agents under normal laboratory conditions, evidently under boiler pressures assume such a rôle and degenerate into sodium formate and free caustic soda.

It is possible to go further into the theory and show that, at about 400 deg. fahr., two molecules of sodium formate water can degenerate, with the elimination of oxygen and the production of caustic soda and sodium acetate. Further, a possible reaction is the combination of the acetate and formate with the reformation of soda carbonate, and the production of acetaldehyde. This new substance is volatile and the rest of it may polymerize into complicated organic compounds, which, acted upon by the free caustic soda, blacken scale formations.

We are all still in the field of intelligent experimentation as to just what is occurring under boiler conditions, but it may be stated with certainty that caustic soda can invariably be found, free oxygen liberated, and at least some formaldehyde produced wherever sodium carbonate exists under a steam pressure greater than 100 lb.

Effect of Caustic Soda Produced by Decomposition of Soda Ash Under Boiler Pressure

With definite evidence then in hand that caustic soda is produced through the decomposition of soda ash, we are now in a position to consider the effect of such caustic soda, and similarly, of course, the effect of caustic soda when added directly as feedwater treatment.

In 1912 a certain boiler distress occurred at the University of Illinois which was investigated by Prof. Samuel W. Parr of that university. The water in question at Urbana, Ill., was unique in character in that it was almost free from sulphates and had from 60 to 70 parts per million of free sodium carbonate. The boiler distress showed first in the form of fine cracks which developed and proceeded either from rivet holes to the surrounding plate, or from rivet hole to rivet hole, or from rivet holes to the edge of the plate where there is no tensile stress whatever. It is interesting to note that these cracks always occurred below the water line and always in conjunction with a leak or other condition, which promoted the concentration of soluble material to the saturation point. The general conclusions arrived at by Professor Parr and his associates were as follows:

1 Caustic soda of sufficient strength attacks iron with the generation of hydrogen.

2 Hydrogen in the nascent state, whether generated by alkali or acid, enters into the texture of the iron in a way to modify its physical properties.

3 The hydrogen effect, at least in its first application, is transient, and after a period of rest or freedom from the hydrogen action, the iron reverts to its normal condition.

4 Sodium carbonate is without action on iron; there is, therefore, no generation of hydrogen. The hydrolysis of sodinm carbonate is directly dependent upon the temperature maintained, the withdrawal of the vapor of CO_2, and the admission through the feedwater of carbonated water. It is evident, therefore, that the chemical activity would vary with the ratio of hydrolization or the degree of concentration of the sodium hydroxide.

5 Certain accompanying salts, as the chromates, have an inhibitive effect. Other salts, as sulphates, have at least the effect of acting as diluents. The limits of concentration for maintaining a condition which would be below the danger point have not been studied, but are the features of the case which are of the utmost importance. A continuation of experiments along the lines suggested is in progress.

To say just where the concentration of soda ash and consequently caustic soda becomes dangerous, would be impossible. There are no definite limits which can be placed since the presence of other salts, sulphates and chlorides of sodium, etc., have an inhibitive effect. Consequently larger amounts of soda ash may exist safely in a boiler, in so far as the action on iron is concerned, when the amount of sodium sulphate is larger. The question of excessive soda ash must always be considered in a conjunction with a zeolite softener when the feedwater contains high temporary hardness. It will be recalled that this temporary hardness is converted into sodium carbonate by the action of the zeolite and proceeds to concentrate in the boilers. It is indeed highly advisable that in plants where zeolites are used the concentration of water be tested at frequent intervals and the boilers drained and refilled with fresh water at such times as in the opinion of an expert this should be done. This concentration proceeds differently at different seasons of the year with the fluctuation of the raw water and the varying percentages of condensate and make-up always present in industrial plants from season to season.

In Albany, N. Y., where the author has been checking up an industrial plant on soda concentration, the analysis of the raw water varied from 4.4 to 7.2 grains of lime carbonate per gallon. This was naturally converted to the corresponding sodium carbonate by the action of the zeolites, and on the basis of about $33^1/_3$ per cent make-up these boilers tested as follows:

Boiler No.	1	2	3	4
Sodium carbonate, parts per million	574	470	483	265

Boilers Nos. 1 and 2 had been refilled with fresh water 12 days previous to these tests, and Nos. 3 and 4 six days previous. In the summer time when all this water will be make-up, the concentration will proceed almost three times as rapidly.

Effect of Cylinder Oil in the Feedwater

There is a definite type of installation in which the returns from engines discharge their drips to the boiler feedwater, and in a number of cases the oil which should be removed by means of separators or other devices has been incompletely taken care of.

On the surface it would seem that the oil entering the feedwater would only be chemically active in so far as its compounding was concerned, and since the average cylinder oil contains between 2 and 8 per cent of organic compounds, it would seem as if only this small percentage of the oil could be saponified since the remaining 90 per cent is of mineral character and in laboratory chemistry is unaffected by soda and unsaponifiable. Here again is the unaccountable to account for. In 1916–1917 the author took occasion to fill a boiler with distilled water to which sufficient caustic soda was added so that 100 cc. of the boiler water required 5 cc. N/10

The Absorption of Gasoline From Casinghead Gas by Activated Charcoal

Particulars Regarding a Series of Tests Undertaken to Evaluate the Process When Applied to a Rich Gas, With Conclusions Drawn Therefrom as to Its Limitations

By H. R. AUERSWALD,[1] TULSA, OKLA.

THE absorption of gasoline from casinghead gas by means of activated charcoal is a comparatively recent method which has received some exploitation. It is in many ways superior to any of the methods at present used in the extraction of gasoline, although its use in connection with gases of different qualities leads to some disadvantages.

In view of the many articles that have appeared in technical publications giving publicity to the process and setting forth its various advantages, tests were conducted by the author at the experimental plant of the Gypsy Oil Company at Drumright, Okla., to investigate the process when applied to a rich casinghead gas, such as is produced in the Drumright District. The results of these tests indicate some rather important conclusions, namely:

1 Charcoal will absorb all the gasoline from casinghead gas at practically atmospheric pressure.

2 It is not possible to distill off and condense all vapors absorbed by the charcoal with superheated steam or by dry heat under the pressures and temperatures ordinarily carried in compression plants.

3 Even if all vapors could be condensed, it is impractical to use the process on casinghead gas of over 2.5 gal. per 1000 cu. ft. yield, if it is necessary to return 65 per cent of the residue gas to the leases for fuel.

4 The results obtained by testing the absorption of casinghead gas by means of activated charcoal and later distilling it in the laboratory with glycerine will give less yield than the gross or net yield obtained from the usual physical testing equipment in the field.

5 The investigation has not been carried to a point where it would be able to state whether or not the scheme would be more economical than mineral-seal-oil absorption on a low-pressure gas (about 20 lb. per gal.) of low yield. The mineral-seal-oil plant would be more economical from the view point of fuel gas consumed. However, if the charcoal does not deteriorate the cost of new absorbent would be less than in an oil-absorption plant.

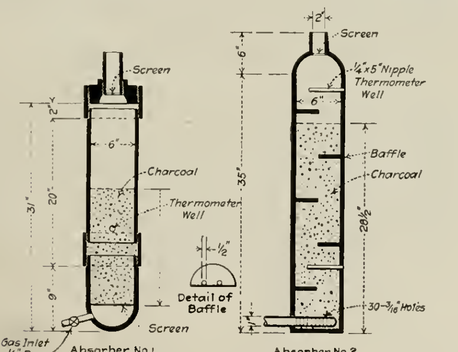

Fig. 1 Details of Absorbers Charged With Activated Charcoal

Details of Apparatus Used in Tests

In these tests two absorbers of special design which provided entrance for casinghead gas, residual gas, and superheated steam were utilized. The details of these absorbers when charged with charcoal and the general arrangement of the other equipment are shown in Figs. 1 and 2, respectively.

As shown in Fig. 2, casinghead gas can be metered to the absorber G or to the compressor C through the meter M. With this arrangement a physical test of the gas may be made by metering the gas before it enters the compressor. In this case the residual gas is allowed to escape at X, while the gasoline condensed is drawn off from the accumulators A and B at D and E. An absorption test with charcoal can be made by metering the gas, passing it thence through pipe F to the bottom of the absorber G. In this latter case the residual gas may be drawn from the top of the absorber G, thence to the compressor C, and by compressing the gas to a suitable pressure it can be determined what degree of gasoline absorption the charcoal effects.

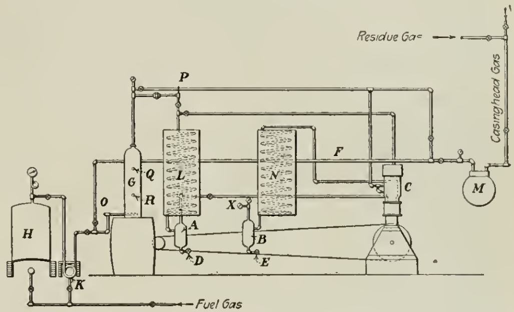

Fig. 2 General Arrangement of the Apparatus Used in Tests to Determine Gasoline in Casinghead Gas by Charcoal Absorption

After the charcoal has absorbed the gasoline, superheated steam can be admitted to the absorber G from the boiler H and the superheater K. The steam and gasoline vapors are then condensed in the condenser L, while any uncondensed gasoline vapors may be transferred to the compressor C, there compressed to any desired pressure, later cooled and condensed in the condenser N, and finally collected in the accumulator B.

Results of Tests

The results of the several tests made with this equipment utilizing the two different absorbers, and under various conditions, are shown in Table 1. From the study of these results the following interesting observations may be made:

1 Test No. 5 shows that the charcoal will absorb 22.5 per cent of its volume and 25.3 per cent of its weight in gasoline if the gas is passed through at the correct velocity. Test No. 2 showed that when the charcoal had been saturated to 15.8 per cent by volume the gasoline began to come through.

2 The best absorption seemed to be effected by a slow speed through the absorber. For the quality of the gas tested the best rate seemed to be from 9 to 12 ft. per min. through the absorber. As the charcoal was 36 per cent voids, this would be a velocity of 25 to 33 ft. per min. through the charcoal.

3 Line 10 of Table 1 shows that in each test, gasoline was condensed from the residue gas by compression. It should be realized, however, that this may have been caused by too high a velocity of the gas or by oversaturation of the charcoal. The charcoal will absorb all the gasoline from the gas if it is not oversaturated and if the gas is allowed to pass through at a slow enough velocity.

[1] District Supt., Gypsy Oil Co. Jun. Am.Soc.M.E.

Presented at a joint meeting of the Mid-Continent Section of The American Society of Mechanical Engineers, and local sections of the American Chemical Society, A.S.C.E., A.I.M.E., A.I.E.E. and A.A.E., at Tulsa, Okla., April 28-29, 1921.

4 Line 14 shows that in tests Nos. 2 and 4 the temperature of the charcoal was raised to a point which would be difficult to maintain in practice. This temperature apparently distills all of the gasoline from the charcoal so far as a flame test on the charcoal afterward will show, but the gasoline vapor formed is of such a volatile nature as to prevent condensation. In all tests except No. 2 the vapors which were uncondensed in accumulator *A* were compressed to 250 lb. gage pressure, and cooled, but they still remained uncondensed.

5 Line 16 gives in percentage the quantity of gasoline condensed by distillation of the charcoal as compared with the gross yield of the gas by physical test. Line 17 shows comparison of the yield by absorption and distillation from charcoal with that obtained when the gross product as made by physical test is weathered to 60 deg. fahr. and "net" yield is thereby obtained.

TABLE 1 RESULTS OBTAINED IN TESTS WITH TWO DIFFERENT TYPES OF ABSORBERS

1 Absorber No.	1	1	1	2	2
2 Test No.	1	2	3	4	5
3 Date	12/16/20	12/20/20	12/23/20	12/29/20	1/5/21
4 Volume of gas run through absorber, cu. ft.	40	80	112	150	180
5 Volume of charcoal in absorber, cc.	7330	7330	7330	13250	13250
6 Weight of charcoal in absorber, cc.	9.17	9.17	9.17	16.55	16.55
7 Gross gasoline contents of gas as determined by physical test, cc. per cu. ft.	17.70	17.70	11.60	20.00	16.90
8 Gasoline contents of gas gross, gal. per 1000 cu. ft.	4.675	4.675	3.070	5.320	4.47
9 Total gross gasoline in gas passed through absorbers, cc.	708	1420	1300	3018	3050
10 Gasoline condensed in residue gas by compression during test, cc.	144	40	78	337	58
11 Total gasoline absorbed in charcoal, cc.	564	1380	1222	2681	2992
12 Efficiency of charcoal as absorbent at the rate which gas was passed, per cent	79.6	97.00	94.20	89.00	98.20
13 Maximum steam temp. passed into absorber, deg. fahr.	600	820	.....	820	720
14 Maximum temp. of charcoal during distillation, deg. fahr.	350	660	400	720	570
15 Total gasoline driven off and condensed, cc.	216	455	572	1024	877
16 Efficiency of the distillation from charcoal compared with gross yield by physical test, per cent	38.3	33.0	46.7	38.0	28.3
17 Efficiency of the distillation from charcoal compared with net yield of physical test, per cent	.....	.....	75.5	54.4	47.8
18 Water condensed during test, cc.	13250	7100	12300	32100	19800
19 Ratio of water condensed to gasoline produced	61:1	15.7:1	21.5:1	32.1	22.6:1
20 Rate of passage of gas through absorber, cu. ft. per min.	5	1.45	2	2.35	1.7

The pressure on the absorber during all absorption tests while the gas was passing through was 4 oz.

In some of the tests the steam pressure on the absorber was raised to 50 or 60 lb. during the distillation.

After tests Nos. 1 and 2 the charcoal was taken out of the absorber and a sample tested with a flame to ascertain whether or not gasoline still remained in it. No evidence was found of the presence of gasoline and the charcoal was perfectly dry and dusty.

6 Line 19 shows that a large quantity of steam must be condensed to produce a small quantity of gasoline. All of the ratios in the column are perhaps high on account of the fact that in all tests steam was introduced for a long period of time to obtain a high temperature in the charcoal. From observations made on test No. 2 it seems that the steam which would have to be forced through the charcoal under ideal conditions so as to distill the gasoline would be 7 parts of water to 1 part of gasoline by volume. It would be necessary under those conditions to generate superheated steam from 7 gal. of water for each gallon of gasoline made.

To generate a pound of steam at 35 lb. boiler pressure and heat it to 600 deg. fahr. requires 1144 B.t.u. Assuming a boiler efficiency of 70 per cent and fuel gas of 1000 B.t.u. per cu. ft., it would require 95 cu. ft. of fuel gas per gallon of gasoline produced.

Because of this large consumption of residue gas it is evident that the method would be impractical on casinghead gas of this quality, especially if residue gas is to be returned to the leases. The residue gas per 1000 cu. ft. would be only about 766 cu. ft., 445 cu. ft. of which would be burned at the gasoline plant, leaving only 321 cu. ft. to be returned to the leases or 32.1 per cent of the original volume delivered. A compression plant handling the same gas efficiently would consume only 90 cu. ft. of the residue gas, leaving 676 cu. ft. for return to the residue system or 67.6 per cent of the original volume.

The consumption of fuel gas would not be such a great objection, however, if the method were used on low-pressure gas of low gasoline content. The gas consumed for fuel, however, would be more than that consumed by an absorption plant of the absorbing oil type, for in the charcoal process the latent heat of the steam is totally lost, whereas in a plant where mineral seal oil is used the latent heat is utilized in evaporating the gasoline.

TABLE 2 DISTILLATION TEST OF GASOLINE

(Product used, 70 deg. B.)

Per cent Off	Temp., deg. fahr.	Per cent Off	Temp., deg. fahr.
I.B.P.	98		
20	140	60	212
20	163	70	220

50	200	95	318 (End Point)

(Recondensed in flask, 1 per cent; loss 4 per cent; gravity of condensate, 68 deg. B.)

7 All the gasoline absorbed in the charcoal was not recovered in any of the tests, but in all tests the gasoline recovered was distilled off before the temperature in the charcoal was raised to 400 deg. fahr. Perhaps a higher temperature than this is needed to reactivate the charcoal, but it is not needed to distill off the gasoline. The exact temperature required could be determined only after a long series of tests.

TABLE 3 RESULTS OF DRY DISTILLATION TESTS

Test No.	1	2	3	4	5	6
Charcoal in flask, cc.	1000	1000	1000	1000	1000	1000
Gasoline poured on charcoal, cc.	200	200	200	200	200	200
Gravity of gasoline, deg. B.	66.5	65.5	71.4	70.4	70.5	70.3

Assumed loss, cc.	8	8	8	8	8	8
Gasoline distilled from charcoal, cc.	121	188	180	208	186	176
Percentage of original gasoline recovered	60.5	94	90	104	93	88
Percentage of accumulated condensate to original sample	60.5	77.2	81.5	87.0	88.3	88.2
Gravity of condensate from the test, deg. B.	70	68.2	69	67.5	68.4	63

Total gasoline put on charcoal during six tests...... 1200 cc.
Total gasoline recovered from six tests............ 1059 cc.
Per cent of total recovered........................ 88.2

After the distillation of the gasoline in test No. 5, residue gas was passed through the charcoal and the same cooled down. When the residue gas was passed through the absorber the temperature of the charcoal was 535 deg. fahr. and the absorber temperature just above the charcoal was 435 deg. fahr. Residue gas of 67 deg. fahr. temperature was passed through the absorber for $2^1/_3$ hours at rates varying from 2 to 3 cu. ft. per min. After 360 cu. ft. of gas had been passed through the charcoal the temperature was still 111 deg. fahr. and the absorber temperature above the charcoal was 165 deg.

TABLE 4 DISTILLATION TEST OF GASOLINE

(Glycerine poured over the charcoal)

Per cent Off	Temp., deg. fahr.	Per cent Off	Temp., deg. fahr.
I.B.P.	130		
10	170	60	206
20	188	70	238
30	190	75	280
40	196	82	294
50	200	89	350

(Gravity of condensate 69.7 deg. B.)

Inasmuch as there had been only 180 cu. ft. of green gas originally passed through the absorber, this test indicated that the absorber would have to be cooled by some other method in addition to residue gas, or the residue gas would have to be recirculated by pumps through the absorber and cooling coils two or three times in order to properly cool the charcoal.

Efficient Operation of Oil-Burning Steam Plants

A Discussion of the Plant Characteristic Diagram, with Particulars Regarding Its Use in the Establishment of a Standard of Performance and in Increasing Plant Efficiency

By C. H. DELANY,[1] SAN FRANCISCO, CAL.

DURING the past ten years there has been a remarkable increase in the efficiency of steam plants, both oil-burning and coal-burning. Ten years ago there were many plants operating reciprocating engines, in which the maximum economy obtained was not over 150 kw-hr. per bbl. of oil.

With the high-pressure steam-turbine plants of the present day a record of 330 kw-hr. per bbl. has been made. This increase in efficiency has been brought about by introducing more efficient machinery and increasing the range of steam pressure in the prime mover. The introduction of the steam turbine to replace the reciprocating engine effected a remarkable saving in the quantity of fuel required. Moreover the steam turbine caused a saving in operation due to the fact that its operation does not depend on the personal element in the plant.

In the old reciprocating engines there were many adjustments to be made by the engineer in charge, and the economy obtained depended very largely on the skill of the operating engineer and the care with which he made the various adjustments. With the steam turbine, however, there is nothing that the operator can do to improve the efficiency after the machine is once installed and placed in good operating condition. While this is true as regards the prime mover, it is not true in regard to many other features of the power plant. In the boiler room particularly there are many points where the operating engineer can effect a saving if he carefully studies the situation and pays attention to the small details of operation. In condensers and vacuum pumps also a great saving can be made if proper attention is paid to maintaining a high vacuum. There is still, therefore, a large field for the operating engineer in improving the economical operation of the plant, and the question of operating efficiency is consequently one worthy of very careful study.

Many tests have been published showing very high efficiency of boilers where fired with fuel oil, efficiencies as high as 80 and 82 per cent being not uncommon in test reports. It is very rare, however, that any such high efficiencies are obtained in the regular operation of power plants. In order to maintain high efficiency in regular operation of a plant, the first requisite is some means of comparing one day's operation with another. In oil-burning electric power plants it is customary to report the economical operation of the plant in terms of kilowatt-hours generated per barrel of oil. This is an excellent method of comparing one day's operation with another, provided there is steady load on the plant and conditions remain the same from day to day. With a variable load, however, such as occurs in an ordinary central-station plant, it is always found that the economy is much better at periods of heavy load, and poorer at periods of light load. Thus it is possible with a fairly heavy load on the plant to secure from 220 to 230 kw-hr. per bbl. of oil without difficulty, whereas with the same plant operating at a light load it may be difficult to secure more than 150 kw-hr. per bbl. of oil.

When the good results are obtained with the heavy load, the operating men pat themselves on the back and consider that they are doing fine, because results are better than the average. On the days of light load when the results are poor, they do not worry but say, "What's the use, you can't expect any results with such a light load." Thus in neither case is there any incentive to improve the economical operation of the station. Another reason for more or less lax methods, so far as efficiency is concerned, is the fact that efficiency must always be secondary to continuity of service. The men at the plant know that any interruption to service will be a matter of close investigation on the part of the management, and they devote all of their energies to maintaining the plant in operation and keeping the lights burning. For instance, if a fireman in endeavoring to carefully adjust the air supply in his boilers neglects to keep up the steam pressure, with the result that the turbine slows down and some of the load has to be dumped, he is sure to be called on for an explanation. If on the other hand he keeps up the steam pressure, but neglects to regulate the air in the proper proportion, there usually will be no complaint; and the boilers may be allowed to operate in this inefficient manner for a considerable length of time. The author is far from disputing the fact that continuity of service is a matter of prime importance, but he does wish to point out that efficiency is a close second. The problem before us, therefore, is to so interest the men who are operating the plants in the matter of efficiency that they will not neglect the various operating details that must have attention in order to secure good results.

In order to improve these conditions and to interest the men in the problem of efficiency, it is essential to devise some means of comparing the performance of a plant from day to day. For this purpose, the diagram here called the "plant characteristic diagram" has been plotted.

The Plant Characteristic Diagram for Comparing Performances from Day to Day

Fig. 1 shows such a diagram for one of the San Francisco stations. It consists merely in the plotting of the oil consumption against the kilowatt-hours generated. Each of the points in this diagram represents one full day's operation, and while the points as shown are more or less scattered, it is apparent that they form a well-defined line. It is thus possible to draw a straight line through the midst of these points in such a way that it will represent the average location of all the points in the diagram. There is nothing new in the use of a straight-line diagram, such as is presented. The line is similar to the Willans line for steam engines, where for throttling engines the total steam consumption plotted against the horsepower output is always found to be a straight line. A similar line for steam turbines is either straight, or very nearly so, depending on the design of the turbine. The use of the Willans line in the design of steam power plants was very ably described by R. J. S. Pigott in a paper read before the A.S.M.E. in 1916.[1] The use of the plant characteristic diagram in improving the efficiency of steam plants has been described very fully by Robert H. Parsons[2] of London; and in fact in describing this system as applying to oil-burning plants, the author is simply amplifying Mr. Parsons' paper on the subject.

Use of Diagram as a Standard for Guidance of Men in Operation of Plant

The diagonal line, having once been drawn through the points as described, may be used as a standard for the guidance of the men in future operation of the plant. Thus each day the kilowatt-hours generated and the oil burned the day before may be plotted on this diagram. If the point so plotted is found to fall below the diagonal line, it is evident that the results obtained are better than the standard. If the point falls above the line, too much oil has been used, and there is something wrong requiring a special investigation; and since the diagram takes in all loads from zero up to the full load on the plant, it is evident that it allows for the poor economy obtained at light loads. It is thus possible for the operating men to know immediately whether they are keeping up to the required standards of efficiency or running behind. They are therefore able to investigate causes of low efficiency immediately while all matters entering into the plant operation are fresh in their minds.

In adopting the standard it would be possible, instead of drawing a line through the average of the points, to draw a line through

[1] Pacific Gas & Electric Co. Mem. Am.Soc.M.E.

Paper presented at a joint meeting of the San Francisco Sections of The American Society of Mechanical Engineers and the American Institute of Electrical Engineers, March 17, 1921. Slightly abridged.

[1] Trans. Am.Soc.M.E., vol. 38, p. 687.

[2] *Electrical Review* (Chicago), Feb. 21, 1920, p. 311.

the best points, thus establishing a standard that would represent the best results obtainable from the plant. Again, it would be possible to establish a standard by drawing a theoretical line below all of the points, this line to be based on the steam consumption of the turbines and auxiliaries, as determined by tests, a boiler efficiency of, say, 80 per cent and the best possible vacuum. In other words, a line representing ideal conditions.

In adopting the average line as the standard it is felt that the men will have greater confidence in the method than if a theoretical line had been adopted. The average line is really a standard that

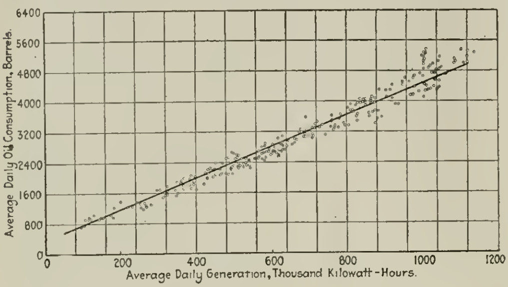

Fig. 1 Plant Characteristic Diagram for a San Francisco Station

has been established by the men themselves. It is not an arbitrary ideal impossible to attain, but as it represents the average already attained, it should be as easy to improve on the results represented by the line as to fall below them.

If the men are successful in improving on the standard each day, it is obvious that the average for a given year will represent better efficiency than the average for the previous year. With all of the points falling below the line on the diagram, another line drawn through the average of these new points would also fall below the original line.

A diagram with the same diagonal line as determined by Fig. 1, but with the points omitted, may be used at the stations each day to plot the results of the day before.

Figure 2 shows a similar diagram, but with the scale altered so as to show the kilowatt-hours generated and the oil burned during a period of 8 hours instead of 24 hours. This diagram may be used by the different shifts in the station so that each shift can check up its own performance and compare it with the performance of the other shifts. A large diagram of this form is posted on the wall of the fire room, and different colored pins to represent the different shifts are inserted each day so that the diagram shows at all times which shift is running above the line and which shift is running below it. This system has a far-reaching effect in awakening interest in the men, and leads to rivalry and competition so that they are extremely anxious to improve the efficiency, and the laxity which previously existed in regard to efficiency is disappearing. As the diagram allows for variations in load, it is possible to compare the day shift when the load is heavy with the early morning shift when there is very little load on the plant, thus making a fair comparison which was never possible with the old method of merely figuring the kilowatt-hours per barrel of oil.

Operating Efficiency and Its Determination

There is one objection to the diagram—it does not indicate the order in which the records are plotted, and therefore does not show whether the results are improving as time goes on. In order to overcome this objection, and also to enable the operation of different plants to be compared with each other, the term "operating efficiency" has been introduced. Operating efficiency as used in this connection means the percentage of standard attained for the day's run. "Operating efficiency" is entirely distinct from "boiler efficiency" or "turbine efficiency" or "thermal efficiency" or "Rankine-cycle efficiency." All of these enter into the operation of the plant in determining the standard. Operating efficiency is merely a comparison of the results actually obtained with the standard.

The method of determining operating efficiency can best be shown by an example: During one eight-hour shift there were generated 313,000 kw-hr. and 1440 bbl. of oil were burned, representing an economy of 217 kw-hr. per bbl. From the diagram it is found that for a load of 313,000 kw-hr. with standard efficiency, there would be burned only 1400 bbl. of oil, which would be equivalent to 224 kw-hr. per bbl., as against the actual result obtained of 217 kw-hr. per bbl. The operating efficiency is therefore 217 divided by 224 or 97 per cent. During another eight-hour shift, where there were only 25,000 kw-hr. generated, the oil burned was 200 bbl., equivalent to 125 kw-hr. per bbl. From the diagram it is found that for 25,000 kw-hr. with standard efficiency the oil burned would be 220 bbl., equivalent to 114 kw-hr. per bbl. The operating efficiency is therefore 125 divided by 114 or 110 per cent. It is thus seen that although in the second case there were only 125 kw-hr. per bbl. obtained, as against 217 in the first, the operating efficiency was actually higher in the second case than in the first.

It is evident from the foregoing that if an operating efficiency of 100 per cent is obtained, it means that the economy of the plant is the same as the average of last year, since last year's records were used to establish the standard. If more than 100 per cent operating efficiency is obtained, the results are better than last year, and if less than 100 per cent is obtained, they are worse. It is obvious that this method of determining operating efficiency makes allowance for inefficient machinery, and it is just as easy to obtain 100 per cent operating efficiency in a plant having old-fashioned turbines of poor design as in a plant having the most up-to-date machines, for the standard is based on the actual records of the plant in question.

Fig. 3 shows the operating efficiency of one of the plants plotted for each day during the months of January and February. In this diagram the horizontal line at 100 per cent represents the standard efficiency and the zigzag line the actual operating efficiency obtained each day. The records show a gradual improvement in the operating efficiency during the period, which is a direct result of the attention to small details brought about by this method of checking up efficiency.

In addition to the use of the diagram for setting standards and creating interest among the men, a system of weekly and monthly reports and bulletins has been adopted. The weekly report, which is made out by the efficiency man at each station, gives the operating efficiency for each day and the average for the week, and in addition a brief statement of some of the more important instrument readings such as flue-gas analysis, vacuum, feedwater temperature, and steam consumption of turbines at different loads. The monthly report which is made out at the office and sent to

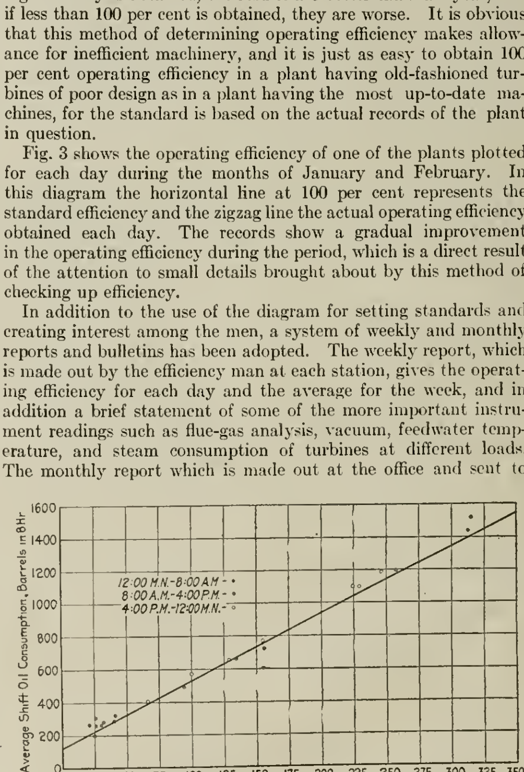

Fig. 2 Plant Characteristic Diagram with Scale Altered to Show Results Obtained on an 8-Hour Shift

each station includes a diagram of operating efficiency similar to Fig. 3 for all stations plotted on one sheet, together with a brief statement of comparative results obtained and suggestions for improved methods. A liberal use is made in the stations of flowmeters and other instruments that serve as a guide to the firemen in the proper regulation of their fires.

Since the diagonal line in the plant characteristic diagram is usually a straight line, it can of course be represented by a simple equation, namely:

$$y = a + bx$$

where y is the oil consumption in a given period in barrels or pounds, x the kilowatt-hours generated in the same period, and a and b are constants.

Evidently the constant a is equal to y when $x=0$, or in other words a represents the quantity of oil burned for zero load; that is, the amount required to keep up steam on the boilers, keep the turbine running up to speed, operate the vacuum pumps, circulating pumps and other auxiliaries, and keep the entire plant in readiness to take on load at a moment's notice. Obviously a will be larger if two turbines with their auxiliaries are kept in operation than only one, so that its value depends on the amount of load the plant is expected to take on. Where a plant is operated as a stand-by to a hydroelectric system and is kept in readiness to instantly pick up its full load in case of trouble, a will have a higher value than where it is possible to gradually shut down the turbines one after the other as the load falls. The constant b evidently represents the additional amount of oil burned in proportion to the load carried on the plant. It determines the slope of the line in the diagram, and is large for uneconomical turbines or engines and small for the most efficient types. The equation of the line in Fig. 2 in terms of barrels of oil and kilowatt-hours for an eight-hour shift is—

$$y = 120 + 0.0041\ x$$

Other Uses of the Plant Characteristic Diagram

The characteristic diagram may be used for many other purposes besides the overall efficiency of the plant. By plotting the steam generated against the oil burned in one diagram, and the steam consumption against the kilowatt-hours generated in another, it is possible to study the boiler-room and engine-room operations separately, and thus quickly locate the cause of low efficiency. By setting separate standards for the boiler-room and engine-room crews, responsibility can be more definitely fixed and the advantages of the system of operation greatly enhanced.

Since boiler efficiency usually decreases quite rapidly as the capacity increases above the boiler's rating, a single boiler will naturally have a curved characteristic. In a plant containing a large number of boilers, however, the boiler-room characteristic will be approximately straight until the load exceeds the economical capacity of all the boilers in the plant, after which it will begin to curve upward. A curved line, based on previous performance, is just as satisfactory as a straight line for setting standards and calculating operating efficiency in the manner described. Fig. 4 shows the power used by electric auxiliaries in a station, plotted against the total generation, and is of interest in showing that the points do form well-defined straight lines, and that the same methods may be used for standardizing these items as for fuel consumption and steam consumption.

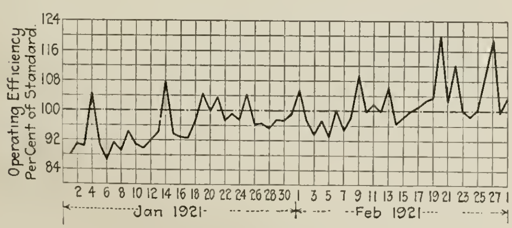

Fig. 3 Diagram of Operating Efficiency of a Plant Over a Two-Months' Period

To sum up, the essentials for securing the best efficiency in power-plant operation are:

1 A fair standard by which the daily performance can be measured and compared with previous results, at the same time giving the operating men a definite goal to work to.

2 Means of comparing results obtained by different groups of men, such as different shifts of one plant or the crews of different plants, and the posting of this comparison so that the men can see the results of their efforts

3 A system of reports that keeps up the interest of the men. combined with suggestions and advice that show where losses occur and how they may be avoided.

If the operating men are kept interested, see the results of their work, and have a definite standard to reach, they will do their best. As interest flags some sort of bonus or prize for the crew showing

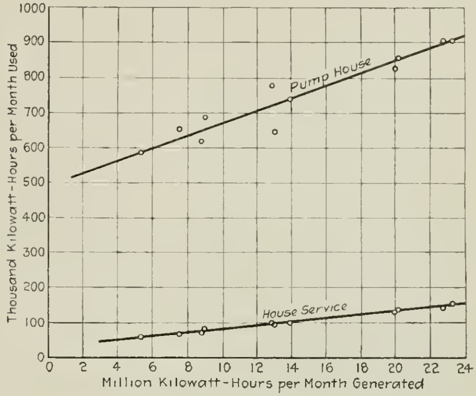

Fig. 4 Power Used by Electric Auxiliaries in a Station, Plotted Against the Total Generation

the best operating efficiency will stimulate them to greater effort, and by guiding this effort by means of thoughtful analysis of the technical features of the power plant, maximum efficiency may be obtained.

The Trent process of cleaning coal, developed on a result of certain suggestions made during the war by Walter E. Trent to the War Inventions Board, consists in agitating together powdered coal, water and oil. This produces a partly de-ashed plastic fuel, called an "amalgam," the oil selecting the coal particles and largely excluding the water and ash. The amalgam can be freed from water mechanically held by working, much as butter is.

This amalgam can be burned in several ways; for example, it may be shoveled or forced through pipes by pressure; it can also be stored under water if desired.

For pulverizing fuel, wet grinding presents many advantages over dry grinding, provided the water can be eliminated afterward.

To be able to reduce the ash in coal may make available great quantities of low-grade coals and material now considered as waste at the mines.

If an oil is used that can be distilled at a temperature below the distilling temperature of the coal, powdered fuel is reclaimed from the amalgam and the oil may be reused. If a heavy oil be used and distilled to dryness, a coke product may be recovered, although the coal may have had no coking quality. If the distillation proceed only to a heavy pitch, a mass suitable for briquetting may be made.

In distilling oil mixed with a finely powdered material the distillates are similar to those obtained by distilling under pressure so that the distillation of an amalgam of coal and oil gives quantities often more favorable than the sum of the separate distillations of the coal and the oil.

The amalgam can be used for a gas-making fuel, and gas-house-tar emulsions can be dehydrated by mixing with powdered coal, the amalgam being retorted for further gas making.

Graphite ore can be separated from its gangue, and coke can be separated from flue dust by using the Trent Process. Clean coal in anthracite sludge will make an amalgam if oil is added.

This brief sketch of possibilities revealed by small-scale laboratory work shows that the field for investigation and development is large. The general results show that real benefits are physically possible by treating coal in this manner.—From an article by O. P. Hood, Chief Mechanical Engineer, U. S. Bureau of Mines, in *Power*, Aug. 2, 1921, p. 196.

DIE SINKING AND METAL PATTERNMAKING BY AUTOMATIC MACHINE

(Continued from page 588)

unusual layout which could not have been accomplished in the old way.

There is another very important point which must appeal powerfully to the thoughtful engineer: A mechanical method which makes of die reproduction merely a routine manufacturing proposition insures constant use and employment of correct dies; the necessity for keeping or the temptation to keep in use dies that have sunk, checked, or spread, is removed. The resultant decrease of rejections and scrap, with a consequent saving of labor and material, is quite evident. What this means to the growth of an industry may be left to the imagination.

Fig. 14 shows a roll-cutting machine. This is a three-dimension automatic machine which cuts a pattern intaglio or relief on the periphery or the inside of cylindrical surfaces. It is useful on embossing and forging rolls for rubber, metal, lace paper, male and female, and particularly for cutting molds for glass.

The propeller-carving machine shown in Fig. 15 is obviously not a die-cutting machine, but is of interest because it shows a very useful application of the principle of the duplicator. This is a very productive machine and capable of cutting accurate and true propellers of any desired shape of pitch. It has records to its credit of 50 large propellers in 8 1/2 hours out of the fullg-lued blank, cutting down to size, ready for sanding.

Fig. 16 shows another interesting applic tion of the reducing machine, designed to overcome the difficulty of getting a smooth and uniform bucket on the wheels of the steam turbines used in connection with torpedoes. The principle is the same as that previously described in connection with the reducing machine for cutting ellipses, with the addition of a special automatic indexing mechanism which carries the turbine wheel and a templet or model the exact shape of the outer contour of the bucket, but four times its size. Spiral end mills and a roller tracer are used.

It has been many times reiterated that without the munitions produced by the American industries, including the machinery, tools, and the great quantities of articles that were so essential, the late war could not have been successfully carried on.

In this connection it may be said that automatic die-sinking machines not only produced many thousands of dies in this country but were also used in the British, French and Italian armories and artillery plants. They supplied dies for howitzers and field guns, for turbines and other parts of torpedoes, for Liberty motor parts, saddlery, shells, surgical instruments, bayonets, trench tools, hand grenades, Emergency Fleet and other marine forgings, aircraft telephone reels, navy chains, submarine parts, horseshoes and tractors.

The question naturally presents itself, how could all these thousands and thousands of dies have been produced had man power been the sole source of supply?

UTILIZATION OF LOW-GRADE COTTON

(Continued from page 596)

body, wiry, of good staple and possesses excellent spinning qualities, permitting the use of less twist and the securing of a higher production. The cleaning machine produces the most remarkable results in cleaning all these types of cotton and makes it possible for a mill to use such cotton in producing many kinds of goods.

On a unit of twenty machines in commercial cotton cleaning where the cotton is rebaled, the cost is less than 1 cent per lb., taking everything into consideration except the shrinkage in stock. This unit of machinery will clean about two bales per hour. In 1920 the profit was from 5 to 7½ cents per lb., and at present the author believes it to be from \$20 to \$25 per bale.

In a manufacturing plant cotton could be taken to the cleaning outfit, opened, cleaned and blown into the picking department. In order to mix this stock properly a mechanical mixer should be used. To reclaim card strips or comber noil the cleaning machine should be installed in the picker room. As the strips are taken from the card, they can be run through the machine and mixed with the cotton in such a percentage as is necessary in number up to and including 40s and then forgotten.

Our machine builders now make equipment to manufacture any kind of product required. What is known as the "coiler" system is used on hard yarns and is perfected to spin good yarn from very low stock. The greatest difficulty has been overcome by being able to clean this stock properly and to mix it in absolutely uniform batches. Most of this low-grade product, especially in Europe, was manufactured on what is known as "woolen machinery." The Europeans were successful because of their low-priced labor and the great care taken with cleaning and mixing. We have learned this and with our improved machinery are in a position to take any raw product and utilize it as efficiently as they.

WATER TREATMENT FOR BOILERS

(Continued from page 600)

normal sulphuric to neutralize it. The cylinder oil analyzed as follows:

Flash point	520 deg. fahr.
Fire test	590 deg. fahr.
Gravity at 60 deg. fahr	25.7 deg. B.
Viscosity at 210 deg. fahr. (Saybolt)	120 sec.
Fat (as tallow)	5.2 per cent
Free acid (as oleic acid)	0.12 per cent

One quart of this oil was injected into the boiler, which was operated at 125 lb. pressure. At the end of three days the water was just faintly alkaline to phenolphthalein, although there was theoretically nothing in that water which should have absorbed the alkali.

THE ABSORPTION OF GASOLINE FROM CASINGHEAD GAS

(Continued from page 602)

After three tests in which steam had been used for distillation, it was demonstrated that all the gasoline could not be distilled and condensed by this method. It was then decided to investigate distillation by dry heat.

The apparatus used in this test was a standard 1000-cc. distillation flask and copper condenser. The distillations were conducted as follows: 1000 cc. of charcoal was placed in the flask and 200 cc. of low-gravity gasoline poured over it. The gasoline used was a drip product of 70 deg. B., with an initial boiling point of 98 deg. fahr. The distillation test of Table 2 shows that it was a very stable product which could be distilled and condensed at atmospheric pressure without excessive loss.

Table 3 shows the results obtained when dry distillations were made by saturating 1000 cc. of the charcoal with 200 cc. of the gasoline under consideration.

The same charcoal was utilized in all tests, but after each distillation the charcoal was cooled down to room temperature before another charge of gasoline was tested.

From Table 3 it is to be noted that in the distillation of gasoline from charcoal by dry heat a greater loss is encountered than when the gasoline is distilled alone. The contact of the gasoline with the charcoal seems to render a certain part of the vapor more volatile. Thus, the use of charcoal for testing casinghead gas, if distilled dry, would give an incorrect yield when compared to the gross or net yeild obtained by the use of a compression physical testing equipment.

A test was conducted to determine whether or not all of the gasoline contained in a certain sample of charcoal could be distilled off and condensed if glycerine is poured over the charcoal containing the gasoline.

A 500-cc. distillat on flask was set up and 250 cc. of charcoal placed in it. 100 cc. of gasoline of low gravity was then poured over the charcoal, after which 150 cc. of glycerine was added. Gasoline of 71 deg. B. was used which had a 4 per cent loss in its own fractional distillation.

Inasmuch as the boiling point of the glycerine with charcoal is 350 deg. fahr. the test was stopped at that point.

Results of this test indicate, as shown in Table 4, that even in the presence of glycerine it is not possible to distill off and condense the original quantity of gasoline in the charcoal without an unusually high distillation loss. In this particular case the results obtained show an unaccounted-for loss to the extent of 7 per cent.

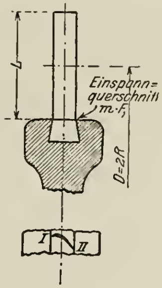
SURVEY OF ENGINEERING PROGRESS

A Review of Attainment in Mechanical Engineering and Related Fields

Steam Turbines for Maximum Loads

By A. LOSCHGE

THE author believes that the development period of the steam turbine, which has been extremely rapid and at times precipitate, is about over. Out of a plethora of inventions only a few types of construction have survived and these have been adopted by practically all turbine builders and are very nearly the same everywhere, notwithstanding material differences in design and construction of metals. These types represent mainly combined turbines with high- and low-pressure stages and for a number of years turbine designers have endeavored to improve and simplify these combined turbines, their efforts being mainly directed toward increase of speed and reduction in the number of stages. As the result of this, it has become possible to employ a speed of 3000 r.p.m., which is the highest that can be used to drive a 50-cycle alternator, and has been applied to increasingly large units of output. How well turbine designers have succeeded in this direction is shown by the fact that the maximum output, that is, the output which can be secured from a turbine unit at the maximum speed of 3000 r.p.m., has increased from 6000 hp. in 1912 to 8000 in 1914, and to about 25,000 in 1921. It is clear that this tendency has very great economic importance and that from now on all turbine builders will have to construct maximum-output turbines.



FIGS. 1 AND 2 TURBINE BLADES
(*Einspannquerschnitt* = Cross-Section at Fastening.)

From this the author proceeds to a discussion of the magnitudes which determine the value of maximum output of a turbine, the technical difficulties which have to be overcome in order to make a higher output possible, and finally the ways and means adopted by various concerns to overcome these difficulties. Because of lack of space only certain parts of the articles can be here abstracted.

Importance of Blade Length in the Last Turbine Stage. The magnitude of maximum output of a turbine is in the first place determined by the length of the blades in the last turbine stage and there are certain conditions which determine the maximum possible length of the longest blade at each circumferential speed u. It was found at the start that the ratio—

$$\frac{\text{average diameter of wheel } D}{\text{blade length } L}$$

should not be less than 5 in the utmost case, since otherwise the blade passage becomes too wide on the outside and too narrow on the inside, which causes a very uneconomic utilization of the steam. From this limiting value $D/L = 5$ it appears that for constructive reasons for a given speed of rotation n the values for L for any circumferential speed u should not exceed those given in the following table:

u (meters per second)	100	125	150	175	200	225	250
D (meters)	0.637	0.796	0.956	1 114	1.274	1 433	1.592
$L_{\max I}$ (at $D/L_{\max I} = 5$) meters	0.127	0.159	0.191	0.223	0.255	0.287	0.318

The blade length $L_{\max I}$ is computed from the equation

$$L_{\max I} = {}^1/_5\, D = {}^1/_5 u/(\pi n/60) = {}^1/_5 u/(\omega/2) \qquad \text{[1]}$$

Stresses in the Blades. A second consideration which tends to limit the maximum length of a blade has to do with the requirement that the blade should have a sufficient factor of safety with respect to its mechanical strength.

Turbine blades are stressed in two different ways, namely: in tension by the centrifugal force of the mass of the blade, and in bending as a result of the pressure which the steam jet exerts on the blade and—in superpressure turbines—also by the difference between the specific steam pressure on the entrance and exit sides of the blades. The tensile stress is determined in a simple manner.

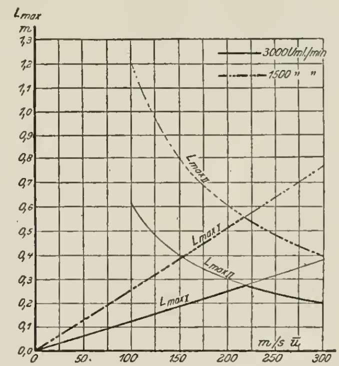


FIG. 3 DEPENDENCE OF MAXIMUM BLADE LENGTH ON THE PERIPHERAL SPEED
(*Uml./min.* = r p.m.; *m/s* = meters per sec.)

If F is the cross-section of a blade in sq. cm., which may be assumed to be the same throughout the blade, and if L is the length of the blade, R the average diameter of the wheel in meters, σ_z the tensile stress in kg. per sq. cm. in the cross-section of the blade at the fastening—which should have an area of mF sq. cm., where m is equal or less than unity (Figs. 1 and 2)—then the centrifugal force is—

$$C = \frac{FL\,\gamma u^2}{1000\,gR} = m\,F\,\sigma_z$$

From this may be computed the specific stress

$$\sigma_z = \frac{\gamma\, Lu}{1000\, mgR} \quad \frac{2\,\gamma\pi}{60\times 1000\, mg}\, nLu = \frac{1}{C}\, n\, L\, u$$

and also the maximum length of blade $L_{\max II}$ that will withstand a given centrifugal stress, assuming certain values for m, u and σ_z:

$$L_{\max II} = \frac{C\sigma_z}{\gamma\, n\, u} \qquad \text{[2[}$$

As regards the bending stresses on a turbine blade, data are available from Stodola's book on steam turbines, (4th German edition, pp. 236 ff.). In many cases these bending stresses may neglected.

If only centrifugal stresses be taken into consideration and if n and σ_z be taken as constant, then Equation [3] will obtain:

$$L_{\max II} = \frac{e'}{u} \quad \ldots\ldots\ldots\ldots [3]$$

This and Fig. 3 show that the connection between $L_{\max II}$ on one hand and u on the other hand is expressed by an equilateral hyperbola, while the connection between $L_{\max II}$ and u at a constant speed of rotation in revolutions is expressed by a straight line. Fig. 3 clearly shows that $L_{\max I}$ and $L_{\max II}$ represent the greatest permissible leng h of blade for small and larger values of u respectively, and that the greatest length of blade that can be used for a given number of revolutions n likewise increases at first with the value of u and then from a certain value of u on begins to decrease. It should be clearly borne in mind, however, that the value of $L_{\max II}$ has been in the first place determined only with respect to stresses produced by centrifugal force and that the calculation given above is based on certain assumptions which affect the value of $L_{\max II}$ very materially. Among such assumptions is that of equal cross-section F throughout the entire length of the blade. In many cases, especially where the blades are long and subjected to high stresses, the cross-section is reduced toward the head of the blade, the blade being made thinner at the end or narrower in the axial direction. With such a type of blade $L_{\max II}$ can be, of course, greater than it could have been with a blade with equal cross-section throughout.

Finally the numerical value of $L_{\max II}$ depends materially on the value of m. $m = 1$ requires that all weakening of the cross-section should be avoided at the places when the blade is held in the hub, which is easily done in the case of machined plates. On the other hand, in the case of rolled plates the plate is undercut in the insert. For this case $m < 1$ and $L_{\max II}$ has to be made of course smaller than for machined and unweakened blades.

The following table contains values for $L_{\max II}$ derived from Equation [2] with $m = 1, n = 3000, \sigma_z = 1500$ kg. per sq. cm. and $C = 93.9$, and gives the values of $L_{\max II}$ for different values of u:

u (meters per second).....	100	125	150	175	200	225	250
$L_{\max II}$ (meters).........	0.602	0.481	0.401	0.344	0.301	*0.268*	*0.241*

A comparison of this and the previous table shows that under the above assumptions $L_{\max II}$ passes into $L_{\max I}$ at about u = 200 meters per second. The actual maximum blade length for each peripheral speed is indicated in both tables by italics. If one takes into consideration the bending forces in addition to the centrifugal stresses it is found that the passage from $L_{\max I}$ to $L_{\max II}$ takes place likewise under 200 meters per second.

In Fig. 3, in addition to the curves for n = 3000 r.p.m. are also given the curves for n = 1500 r.p.m. From this and Equations [1] and [2] it would appear that for the same values of u the maximum length of the blades increases with the decrease in n. (*Zeitschrift des Vereines deutscher Ingenieure*, vol. 65, no. 28, July 9, 1921, pp. 739–744, 10 figs., *t*.—Only the first part of the article has been abstracted. Further abstracts will appear in a early issue.)

Short Abstracts of the Month

AIR MACHINERY

Drier Air For Blast Furnaces

Air Conditions in Blast-Furnace Plants, with Special Reference to Moisture Content in Air, J. Bronn. The author made an extensive investigation of moisture content in air at various places around a blast-furnace plant, using a special recording apparatus called a "thermohydrograph," made by R. Fuess, of Steglitz, Germany. This apparatus records both the temperature of the air and the moisture percentage, from which it becomes possible to determine by proper tables the weight of water in a cubic unit of air.

These investigations have shown that the moisture content in air at an altitude of 30 meters (98 ft.) above ground level is about 20 per cent lower than at the ground level, both measurements being made in the neighborhood of a blast furnace. This led to an inquiry as to whether such a difference is universal or due to specific conditions surrounding a blast furnace, and surprisingly enough the author discovered that no reliable information was available as to moisture content at even low altitudes above the ground. A further investigation has indicated, however, that a difference of moisture content as high as that observed in the present instance was by no means universal. and was probably due chiefly to the fact that air even at an elevation of 100 ft. above the ground in the neighborhood of a blast-furnace plant is very much colder than at the lowermost level, and the author ascribes this to the tremendous amounts of heat delivered to the air from blast-furnace or rolling-mill plants.

In fact, he states that, roughly, each square meter (10.7 sq. ft.) of the area of a blast-furnace plant is heated daily by 3 kg. (6.6 lb.) of coke or coal, in addition to which there is a very large amount of water discharged every minute in the various cooling and washing devices. This leads the author to the conclusion that in order to obtain as dry air as possible for the blast furnaces it is of advantage to take this air from as high an elevation as possible.

In order to meet these conditions when in 1912 the blowing-engine house at the Rombach mills was being reconstructed, it was decided to place the suction orifices of all the eight gas-driven blowing engines into a common suction tower 42 meters (138 ft.) high. The new blower unit was not completed until 1915 and then war conditions made measurements difficult, particularly as neither an air hygrometer nor a registering moisture indicator could be used in connection with the suction tower, because of the very great vibration of the air flow, and all measurements had to be made by weight analysis which is a very time-consuming process. Nevertheless, fifty-three measurements were carried out, with the result that it was found that air taken through the top of the tower contained on an average 12 per cent less moisture than air at the ground level.

In this connection it is of interest to note that it was found that when the wind came from the east and particularly from the north-east, there was a rapid increase in the moisture content in air coming through the suction tower. This is explained by the fact that at the distance of some 50 meters (164 ft.) from the tower was located a tall stack discharging the exhaust of all the engines driving the blowers, and it was evidently the vapor from this exhaust that tended to increase the moisture content in the air.

The latter part of the paper presents a calculation indicating the importance from the point of view of economy of reducing as far as possible the moisture content in the air. This computation does not materially differ from several similar computations that have been published in this country. (*Stahl und Eisen*, vol. 41, no. 24, June 16, 1921, pp. 813–820, 7 figs. *e*)

BLAST FURNACES (See Air Machinery)

ENGINEERING MATERIALS (See also Metallurgy)

Alloys of Tellurium with Some White Metals, J. H. Ransom and C. O. Thiem. The experiments carried out covered alloys of tellurium with 50-50 tin-lead solder, and with lead, tin, zinc, aluminum and zinc-base die-casting metal.

Tellurium was added to the molten metals in comparatively small percentages. When it was added to the solder it burst into a glow and then seemed to form hard lumps which only slowly and in part disappeared. No samples of these lumps have been secured for analysis.

As regards the results obtained, it was found that in some cases the addition of tellurium reduced the amount of copper in the solder. No appreciable difference was found as being due to the addition of tellurium to lead and tin, but in the case of aluminum the tensile strength increased from 13,940 to 14,810 lb. and the elongation from 18.5 per cent to 28.5 per cent. In the case of zinc, no difference in elongation was found, but the tensile strength increased from 4955 lb. to 5510 lb. per sq. in. On the whole, it would appear that where metal dissolves tellurium the hardness and tensile strength are increased to an appreciable extent. In all cases investigated it is probable that tellurides of the metals are formed and that these are little soluble in the molten mass. (*Chemical and Metallurgical Engineering*, vol. 25, no. 3, July 20, 1921, pp. 102–103, 1 fig., *e*)

Cast Iron in the Construction of Internal-Combustion Engines, P. W. P. It is claimed that when cast-iron bars are subjected to prolonged heat treatment at temperatures between 575 and 600 deg. cent. a partial decomposition of the pearlitic carbide takes place and that the extent of decomposition of carbide is greater in the comparatively silicon-rich alloys. This decomposition is almost complete when the silicon content exceeds 2 per cent.

The author therefore expresses the opinion that no subsequent treatment, no matter how thorough, will entirely overcome distortion due to repeated application of heat and that little advantage, if any, is to be gained from the standpoint of release of internal stresses set up by the primary crystallization produced during the cooling or freezing of the iron. He believes that it is necessary to select a material having a much lower silicon content than that contained in commercial gray cast iron, and he suggests that 1 per cent be considered the maximum for material to be used for cylinders and pistons of internal-combustion engines. (*Engineering and Industrial Management*, vol. 5, (new series), no. 26, June 30, 1921, pp. 736, *p*)

Effect of Crusher Screenings in Concrete. Data of tests carried out in Canada which are claimed to show an increase in strength of concrete through use in the aggregate of crusher screenings in quantities up to 20 per cent.

Tests carried out have shown among other things that when 5 per cent of the weight of the crushed-stone proportion was added in the form of screenings, which is less than 3 per cent of the total mixture, the strength was increased from 2223 to 2729 lb. per sq. in., or 22 per cent. This is, however, not an entirely new fact.

Tests were also made to determine the effect of screenings from the upper rock as compared with those from the lower rock. It was found that mortars made with crushed sand are considerably stronger than those made with river sand. (*Cement and Engineering News*, vol. 33, no. 7, July 1921, pp. 19–21, 1 fig., *ce*)

Latent Heats of Fusion of Nickel and Monel Metal. Walter P. White. Description of apparatus and methods used for determination of the specific heats of solid or liquid metals. The results found indicate that formerly published figures are in error by about 30 per cent.

The general method employed was that of heating the specimens of metal and then dropping them into a water calorimeter. The metal specimens were handled in closed and nearly exhausted silica glass tubes which protected them from oxidation and supported them while melted. Before exhausting, the tubes were filled with nitrogen to protect the metal during the inclosing process. The total heat of melted nickel is found by pouring the metal directly from crucibles into the calorimeter, using the first appearance of solidification to indicate the temperature—which was therefore the melting point (some practice was required in catching the right moment for pouring).

The latent heat of nickel was found to be 73 calories per gram, 17 calories greater than the determination of Wust (1918). The latent heat of monel metal, 68 calories, is in excellent agreement with that of nickel. (*Chemical and Metallurgical Engineering*, vol. 25, no. 1, July 6, 1921, pp. 17–21, 2 figs., *e*)

FUELS AND FIRING (See Power-Plant Engineering)

HOISTING MACHINERY

The Graphical Dynamics of a Winding Engine, Charles D. Mottram. Description of the apportionment of the external losses in a large steam winding engine at a British colliery. These losses are determined at instants throughout a complete wind in horsepower and curves are plotted on time abscissae.

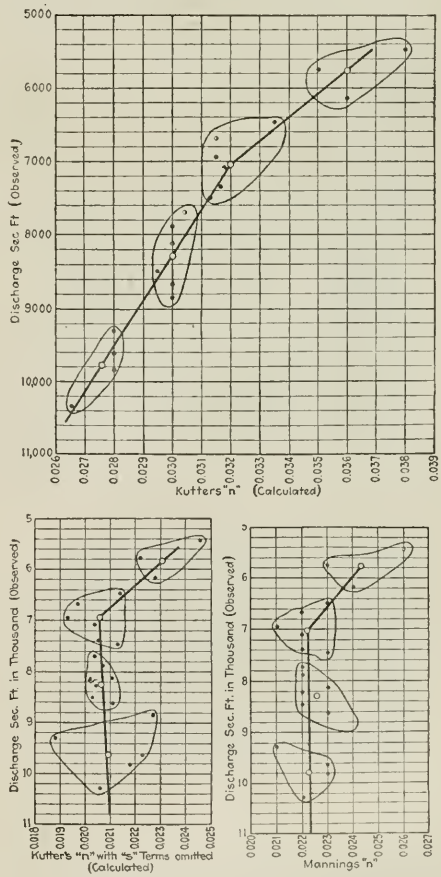
The velocity and acceleration throughout the wind were determined both on the full and on the empty side, this being done from a record automatically drawn by the engine. The record is a diagram showing ordinates proportional to the winding-drum speed in revolutions. On the recorder used in this instance the chart is carried on a cylindrical clock-driven drum varying less than a minute in 24 hours and thus giving an abscissa directly proportional to the time.

The interesting data presented in the paper are not suitable for abstracting. (*The Colliery Guardian and Journal of the Coal and Iron Trades*, vol. 121, no. 3155, June 27, 1921, pp. 1733–1734, 8 figs., *p*)

HYDRAULICS

Manning and Kutter Formulas. In a résumé of four years' intermittent gagings of the flow through the main channel of the Sanitary District of Chicago, contributed to the *Journal of the Western Society of Engineers*, for Sept. 5, 1920, Murray Blanchard, formerly with the Sanitary District, now hydraulic engineer, Illinois State Division of Waterways, Chicago, who made the study, concludes that Kutter's formula to obtain the value of c in the Chézy formula $V = c\sqrt{(Rs)}$ will not apply. The value of n, computed and tabulated from measured discharges ranging from 5,000 to 11,000 sec-ft., is not a constant but increases in value with the decrease in discharge, as shown in Fig. 1.

Similar computation for n with Manning's formula, which for c in the Chézy formula gives $c = 1.486 R^{1/6} n$, shows that n comes out a fairly constant value of 0.220 for all except the low discharge, as shown by Fig. 2.



Figs. 1, 2 and 3 Comparison of Values of n Calculated from Observed Discharges in Main Channel of Sanitary District of Chicago

H. W. King, professor of hydraulic engineering, University of Michigan, in commenting on Mr. Blanchard's equation, states that eliminating the s, or slope terms, will give far more consistent results. Fig. 3, based on the Sanitary District records, gives for n a value somewhat less than 0.021.

Professor King states further that for some time he has been of the opinion that Kutter's formula will give just as satisfactory results without the *s* terms. It is his opinion that the Kutter formula has been used satisfactorily for many years because, in most cases, channels are constructed with slopes so great that the value of *c* is not generally affected by the inclusion of the slope terms. (*Engineering News-Record*, vol. 87, no. 3, July 21, 1921, pp. 96, 3 figs., *ct*)

INTERNAL-COMBUSTION ENGINES (See Engineering Materials; Lubrication)

LUBRICATION

The Carbonization of Lubricating Oils in Internal-Combustion Engines, Frederic H. Garner. The paper discusses the factors which cause decomposition of the oil in the engine, decomposition being considered the fundamental cause of carbonization. According to the opinion of the author, decomposition of oil in an engine can occur in two ways, namely:

First, rapid carbonization due to exposure of the oil (in the form of a fine spray or mist) to the explosion flame causing incomplete combustion of the oil; the result of such carbonization being the production of carbon and asphaltic material.

Second, gradual carbonization of the thin oil film on the piston and cylinder heads at temperatures of 200 to 400 deg. cent., giving first asphaltic material which is changed to carbon by the prolonged action of these temperatures.

The paper describes experiments to determine the evaporation losses and degree of carbonization for various oils and the estimation of the asphalt resin content of lubricating oils.

Among other things it was found that the evaporation losses of lubricating oils of similar boiling-point range were approximately the same whether the oils were derived from Texas or Pennsylvania crude.

It was also found that for similar oils there is a general relationship and that the higher the flash point of the oil, the lower is the amount of asphaltenes formed in a given time at a given temperature. Moreover, the rate of asphaltene formation appears to follow a mathematical law and decreases almost uniformly with rise in flash point and fire point of the oil. Direct carbonization increases much more rapidly than the evaporation loss, both as regards increase of time at a particular temperature and increase of temperature after heating for the same length of time. (*Journal of the Institution of Petroleum Technologists*, vol. 7, no. 26, April 1921, pp. 98–126, with discussion pp. 126–138 and bibliography 139–148, *eA*)

MACHINE PARTS (See Machine Shop)

MACHINE SHOP

Lantern Projector Apparatus for Inspection of Machine Work

Cold Swaging. Second of two articles describing the methods employed in making swaging dies, the first of which was abstracted n Mechanical Engineering, August 1921, p. 546.

An interesting feature is the use of a lantern projector apparatus for the inspection of swaging dies. The machine has a magnification of 50 diameters, which facilitates inspection of the condition of the dies either from a projectograph of the matrix of the die or of a piece of swaged work.

The projectographs reproduced in Figs. 4 and 5 emphasize the value of such an inspection means for detecting imperfections in the die surfaces. Fig. 4 shows a needle of 0.07 in. diameter after being swaged in a pair of dies, and enables the irregularities in the blade, produced either by wear or by improper machining, to be easily detected. Mention has been made in a previous paragraph of the quality of product which may be realized in the manufacture of threaded rods by swaging. The projectograph of swaged threads shown in Fig. 5 is self-explanatory. The thread form, it will be seen, is exceptionally good, although it is not in respect to thread form that the swaging process is most efficient, but rather in the lead.

On precision work such as the sizing of wire or for work encountered in needle manufacture, the existence of worn surfaces must be detected before it has advanced far enough to produce unsatisfactory work. The detection of this wear probably cannot be accomplished with such a degree of positiveness as by the use of the projectograph apparatus. (*Machinery*, vol. 27, no. 11, July 1921, pp. 1018–21, 8 figs., *d*)

Position of Lathe with Respect to Light. The general tendency is to place a lathe, when possible, in front of or near to a window, or under a top light, but only seldom is an effort made to secure any result beyond that of obtaining as ample light as possible.

An engineer who has done a considerable amount of research work in turning is credited with the statement that when a lathe has been moved from a position in front of a window facing to the west to one facing to the north, a much better view of the operations has been obtained.

Artists have for a long time endeavored to have their studio windows face north; weaving sheds and other workshops have also been planned to obtain north lighting. (*Model Engineer and Electrician*, vol. 45, no. 1054, July 7, 1921, pp. 1 and 2, *p*)

Fig. 5 Swaged Thread Projectographed to Show the Contour

Non-Metallic Gears

Design and Manufacture of Non-Metallic Gears, Fred R. Daniels. Description of the methods and processes employed in the manufacture of rawhide and micarta gears.

The raw material from which rawhide gears are made is the green packer hides cured and treated by processes that leaves mainly a fibrous structure. These processes reduce each hide to a thickness of approximately $^1/_{16}$ in., the hide being then blanked into circular disks or into rings or segments according to the requirements of the gear manufacturers. These blanked-out hides are then dipped into a vat of special glue and assembled between steel end blocks until a thickness of from 8 to 10 in. has been reached. Hydraulic pressure is next applied to squeeze out the surplus glue, after which the blank is kept compressed until dry, which may require several days.

Gears made from various fabric-base materials are said to resemble closely each other in physical characteristics. The fabric is first impregnated with compositions (condensation products of phenol and formaldehyde), after which a number of the blanks are bonded together under great pressure and application of heat. The rings or segments are cut from the impregnated fabric and placed in a suitable mold before the pressure and heat are applied.

Rings or segments are used in designs where a spider or bushing is the main support. Such constructions are employed where a stress on the key is likely to be greater than the material itself would be able to withstand if the gear were made of one solid blank. Micarta is frequently mounted on a hub center in such a manner that no additional mechanical retaining means are required.

Rawhide gears should not be subjected to a temperature in excess of 225 deg. fahr., neither must they become wet. Care must be therefore taken to provide suitable storage space for rawhide gears and when not in use the rawhide should be coated with shellac and kept in a cool, dry place. The life of the gear in service is greatly prolonged by the use of a lubricant consisting of a thin mixture of lard oil and graphite. Mineral oils should never be used as a lubricant for rawhide.

On the other hand, rawhide is as strong as cast iron at high speeds and gears are often used with peripheral speeds of from 1700 to 2000 ft. per min. or more. Rawhide can successfully compete with bronze from the viewpoint of ultimate cost, owing to its comparative length of service, but is somewhat higher as regards first costs.

A safe working load for rawhide pinions is 150 lb. per inch width of face for gears of 1-in. circular pitch. The working load for other pitches should be in proportion but should never exceed 250 lb. per inch of face width, and an allowance of from 20 to 25 per cent should be made for such conditions as overload, etc. The above figures apply only to pinions constructed without flanges and may be increased from 10 to 25 per cent for pinions with flanges.

Fabric-base materials are not affected by water or oil, not susceptible to the action of acids or alkaline solutions, and not attacked by rodents. They will not shrink at temperatures under 200 deg. fahr.

The specific gravity of these fabric-base materials is 1.4, the weight 0.05 lb. per cu. in., and the Brinell hardness from 30 to 40. The raw material has a tensile strength, parallel to the laminations, of 10,000 lb. per sq. in.; a compressive strength of from 35,000 to 47,000 lb. per sq. in. perpendicular to the laminations, and from 17,000 to 24,500 lb. per sq. in. parallel to the laminations; and a transverse strength, both parallel and perpendicular, of 17,000 lb. per sq. in. In figuring the strength of gear teeth by the Lewis formula, however, a safe working load greater than 5000 lb. per sq. in. should not be used.

The diametral pitch of gear teeth recommended for service is as follows: For smaller loads up to and including $1/2$ hp., 10 pitch; for 1 hp., 8 pitch; 2 hp., 5 pitch; 10 hp., 4 pitch; 15 hp., 2 pitch; 25 hp., $2\,1/2$ pitch; 50 hp., 2 pitch; 75 hp., $1\,3/4$ pitch; and 100 hp., $1\,1/2$ pitch. When heavier service than 100 hp. is encountered, the design of the gears should receive special consideration. The maximum recommended pitch-line speed is 2500 ft. per min. The greatest length of service for gearing is obtained when there is a good rolling contact; consequently the most desirable condition in non-metallic gear design is where there is a comparatively large number of teeth. Gears having less than fifteen teeth do not furnish good rolling contact, and they wear faster and vibrate more than when a finer tooth is used. It may even be good engineering to redesign the entire gear train in order to use gears of smaller pitch.

The article gives extensive information on the design and machine methods of these gears and also illustrates several of the designs of the gears. (*Machinery*, vol. 27, no. 11, July 1921, pp. 1005–1011, 12 figs., *d*)

Milling Slender Castings. Description of the fixtures and processes used by the Remington Typewriter Co. Of particular interest is the discussion of the effect of rate of feed or distortion of work.

It was found that the rate of feed used for milling has a decided influence on the distortion of such slender parts as the bed and carriage rails of the typewriter. When a fine feed is used there is considerable distortion, but when the feed is coarse the distortion is not great enough to cause trouble.

The explanation given for this fact is as follows: Milling often leaves on the surfaces uniformly spaced revolution marks caused by some irregularity of the cutter such as the presence of a tooth which differs slightly from the others. As this irregular tooth comes around, it strikes the work with greater force than the others. This irregularity while slight, may have, nevertheless, a pronounced effect on the work when the feed is fine because the "peening" action, due to the irregularity of the cutter, is greater or occurs often in a given length with the fine feed than with the coarse feed; consequently there is greater distortion with the fine feed. (*Machinery* (London), vol. 18, no. 456, June 23, 1921, pp. 356–358, 4 figs., *dp*)

MACHINE TOOLS

Inclined Wheel Grinders

Phantom Wheel Grinders, Ellsworth Sheldon. Description of a new type of grinder of American manufacture.

The device was invented primarily for grinding extremely thin pieces of hardened steel. The pieces are not absolutely flat when they come from the hardening process to the grinding operation and will not lie still under the wheel unless packed. Packing each piece to grind first one side and then the other alternately would render the cost prohibitive, even if it were possible mechanically. A magnetic chuck could not be used because some of the

Fig. 6 Parts of the Phantom Grinding Wheel

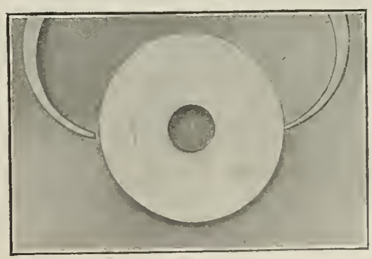

Fig. 7 Ellipticity of the Phantom Grinding Wheel

pieces were so thin that even the pull exerted by it would distort them. To handle these wheels a special bearing was provided, but its character was such that there was no very efficient way of conducting the heat away from the piece being ground. Furthermore, a solid wheel wide enough to cover the surface of the work would quickly sweep the pieces off the chuck or would overheat them, and a very narrow wheel that would enable the operator to avoid both these troubles would take a long time to traverse over the width of the piece, besides being likely to induce distortion because of the slow progression of the hot spot across the work.

It was to avoid these troubles that the "phantom" wheel was developed.

The parts of the phantom wheel are shown in Fig. 6. A standard grinding wheel 7 in. in diameter and of about $^1/_2$ in. width of face was first mounted in the usual manner and dressed to the shape shown in the figure, leaving a very narrow face. A sleeve was then fitted with a pair of collars, one face of each collar being machined to form an angle of about 15 deg. with its axis.

These collars are keyed to the sleeve. The lead bushing of the grinding wheel is then dug out to allow the wheel to tilt to an angle corresponding to that of the collars, a ring nut holding the whole combination together.

When the whole combination is first mounted on the grinding machine the periphery of the wheel does not run true. There are two high and two low spots. In other words, the wheel, though round of itself, will appear to be elliptical. To correct this condition the periphery must be redressed and thereafter the ring nut that binds the parts together must not be slackened; for the wheel that now presents a truly circular periphery to the work is in fact elliptic, as may be seen in Fig. 7, and as is shown by the calipers; the actual difference between the larger and smaller diameter with a wheel initially 7 in. in diameter amounts to about $^3/_{32}$ in.

The grinding action of the wheel is in effect the same as that of a solid wheel of the width equal to the scope of gyration, but the action may be represented as a series of contacts progressing back and forth across the work in a direction at right angles to its lineal advance.

When in motion the solid lines of the wheel disappear and, though the wheel is grinding with the apparent continuity of a solid wheel of 1 in. face and throwing sparks clear across the work, the work is at no time concealed from the operator's view.

Furthermore, because of the narrow surface in contact with the work at any time, comparatively little heat is generated and it becomes possible to cover the entire surface of the work without side traverse and with little danger of drawing the temper.

The original article shows a rather unusual method of dressing the wheel in which the diamond is placed at an angle of 45 deg. (*American Machinist*, vol. 55, no. 2, July 14, 1921, pp. 44–45, 5 figs., *d*)

METALLURGY

High-Temperature-Resisting Alloys for Carbonizing, A. Bensel. In two of the processes of case carbonizing, namely, pack carbonizing and liquid-bath carbonizing, the parts are packed in containers and it is claimed that cast-iron and steel containers are badly distorted in a relatively short time, with the result that it is impossible to load a furnace evenly. It is also stated that cast-iron and steel containers are subject to the formation of scale. While this scale clings to the box it makes the heat penetration poor, and when it drops off the walls become thinner and more heat is supplied to the work than should be.

The material for containers should be such that it will not easily carbonize, is not brittle and is capable of being machined. It should have a high tensile strength and retain much of that strength at the usual operating temperatures.

The alloy developed for this purpose is said to have the following characteristics:

Percentage composition: Nickel, 60; chromium, 12; iron, 26; carbon, silicon, manganese, etc., 2.
Melting point, 2660 deg. fahr.
Safe working temperature, 2000 deg. fahr.
Specific gravity, 8.15; Weight per cubic inch, 0.29 lb.
Specific heat, 0.111 at 100 deg. cent.
Brinell hardness number, 179
Scleroscope hardness, 27 to 30
Coefficient of linear expansion over temperature range from 0 to 100 deg. cent., 0.0000121
Thermal conductivity is 0.0341 cal. per cm. per sec., or a ratio of 1 to 4.888 with soft iron; or expressed in percentage, 20.5 per cent of the thermal conductivity of soft iron

The following tests were made on a 1-in. diameter specimen:

Tensile tests at 70 deg. fahr.:
Elastic limit, 40,000 lb. per sq. in.
Ultimate tensile strength, 54,000 lb. per sq. in.
Elongation, 1.00 per cent
Reduction of area, 2.50 per cent

Tensile tests at 1500 deg. fahr.:
Elastic limit, 20,100 lb. per sq. in.
Ultimate tensile strength, 24,500 lb. per sq. in.
Elongation, 4.00 per cent
Reduction of area, 4.30 per cent

The use of such an alloy made it possible to design a round container with a machined taper-fit cover which goes snugly into the container and closes it as a ground-glass-stoppered bottle. (*Transactions of the American Society for Steel Treating*, vol. 1, no. 10, July 1921, pp. 598-601, *dp*)

PIPE LINES

Economics of Lagging Oil Pipe Lines

Pipe-Line Transportation of Hot Oil. Leonard L. Barrett Discussion of effect of applying insulating coverings to hot-oil pipe lines such as are found in the California, Texas, and Mexican fields, with special reference to the economic results to be obtained by such practice.

The rate of heat loss from a hot-oil pipe line has a governing effect upon the location of stations. As the temperature of the oil drops, due to loss of heat by radiation, the viscosity of the oil increases rapidly and a point is reached where it becomes necessary to install a pumping station and heaters to force the oil along. The low specific heat of crude oil (approximately 0.5) accounts in a measure for the rapidity with which the oil drops in temperature during its passage through the pipe lines, because for a given loss of heat the temperature of the oil will drop twice as fast as would that of water.

The chief advantage of a suitable insulating covering on the pipe line is found in the heat saving effected, as it permits to space farther apart the pumping and heating stations which form the principal element of cost in pipe-line construction. It is stated in this connection that the loss of heat to the air from a pipe covered with a 1-in. thickness of 85 per cent magnesia is 0.45 B.t.u. per sq. ft. of pipe surface per hour per degree temperature difference, while the bare-pipe loss in air is between four and five times as much and the ditched-pipe loss may even exceed that of pipe in air if the ground is wet.

An extensive calculation of the flow of viscous fluids, of spacing of pumping stations and temperature of oil during flow is presented. This is accompanied by temperature-distance curves, viscosity-distance curves, density-distance curves and calculation of thermal efficiencies obtained in practice.

As regards the coefficient of radiation, it is stated that the values given in the article for above-ground insulated lines are very reliable, likewise the values for above-ground uninsulated lines, though the latter have been determined only for still-air conditions and would have to be increased for air in motion. The value of the coefficient for ditched insulated and uninsulated lines cannot be considered as fully reliable.

The discussion of the economic aspects of the question brings the author to the conclusion that insulation of pipe lines would bring the following net savings, (based on present cost): A capital saving of $72,000 per 100 miles, an annual saving of $36,700 per 100 miles and a saving of 3.85 cents per 1000 barrel-mile cost. To this should be added the advantage gained through the protection of the pipe from electrolysis and the steadiness in operating conditions which is gained by eliminating all the trouble due to moist ground during rainy weather. (*Chemical and Metallurgical Engineering*, vol. 24, no. 26, June 29, 1921, pp. 1148–1152, 3 figs., *cp*)

POWER-PLANT ENGINEERING

Economic Features of Pulverized-Coal Firing

Pulverized-Coal Versus Stoker Firing, F. P. Coffin. Comparative data on the value of the two under different operating conditions. The author arrives at the conclusion that where great flexibility of operation is required, pulverized coal may prove preferable.

The development of the underfeed stoker has made the adoption of pulverized fuel more difficult, though improved machinery for its preparation may help in this respect. It is also claimed

that large plants can be equipped for the preparation and burning of pulverized fuel at less cost than for burning coal on stokers.

The most important advantage of pulverized-fuel firing is its ability to handle a wider range of coals than can be burned on stokers and the same furnace is available for burning all grades of coal in pulverized form. Another important advantage is the facility and economy with which fires may be banked and the ease with which they may be restarted when steam is wanted suddenly. This makes pulverized fuel especially desirable where the steam plant is used as a reserve unit either in connection with water power or to carry peak loads.

From a discussion of several large central stations the author finds that the coal consumed in banking fires and bringing them back into steaming conditions was in one instance 3.76 per cent of the annual consumption. In another system with 15 stations feeding into it, 1.5 per cent of the annual consumption, and in a third instance the coal used for maintaining banked fires ran from 5.5 to 6.5 per cent of the total coal used.

In the first of these systems the underfeed stokers could be economically banked, the consumption then being only 35 lb. per hour for each 5000-sq. ft. boiler, but 1500 lb. was required to bring the fire back into condition for operation. When a fire was allowed to go out, 1000 lb. of coal was left on the grate and credited to the plant, while 6000 lb. was required to light a boiler and bring it to steaming condition, ready to put on the line.

When coal is burned on stokers in stations that are used for stand-by service for a considerable part of the year, the consumption in banking fires is an appreciable item of expense. The amount of coal burned during banking periods varies with the service conditions. Banked fires are carried as "hot bank" or cold bank." "Hot bank" or "live bank" consists in carrying full steam pressure and having the fire in condition to get the boiler to the normal rating in from five to seven minutes. A "cold bank" or "dead bank" consists in burning only enough fuel to keep up a low steam pressure. On modern underfeed stokers the average hourly coal consumption during banking is about 0.05 lb. per sq. ft. of heating surface on live bank and 0.02 lb. on dead bank or 7.5 to 10 and 2.5 to 3.5 per cent, respectively, of the fuel at full load.

Where pulverized fuel is used, steam has been held over night with only a small drop in pressure and in the morning about four minutes' firing sufficed to bring the pressure up to normal.

This suggested that the equivalent of dead-banking conditions may be effected by burning fuel only under a single boiler in a battery and by maintaining a steam pressure in the remaining boilers by circulating either steam or hot water through them from the live boiler. This will keep the boilers hot and permit raising the pressure rapidly without undue overstrain.

A further advantage claimed for pulverized fuel is that it is more responsive to delicate control of combustion conditions than solid fuel. On a good station-load factor the investment required for a pulverized-coal installation is comparable with that required for a stoker installation, but as the load factor becomes poorer the pulverized-coal installation will cost less in proportion, provided the fuel requirements are sufficient to enable the preparation plant to operate at a good load factor. (*Power*, vol. 54, no. 2, July 12, 1921, pp. 52–54, 2 figs., *cp*)

POWER PLANTS (See also Pipe Lines)

Cleaning Surface-Condenser Tubes, D. W. R. Morgan. After discussing the economic importance of keeping the condensers clean, the author proceeds to a description of eight methods of cleaning, some of which appear to be very expensive and others lacking in efficiency. The following, however, are recommended for use under certain conditions. The use of adjustable rubber plugs is said to be well adapted to cleaning the tubes when the deposit is of a slimy nature. These plugs are inserted into the tubes and are driven through by compressed air or water pressure. Cleaners of the scraper type are applied in a manner similar to the adjustable rubber plugs. This method of cleaning applies particularly to cases where there is a brittle or hard deposit on the tubes. The sketch in Fig. 8 illustrates the arrangement required for either the adjustable rubber plug or the cleaner of the scraper type, in cases where the condenser head has been removed. The brackets which support the scaffold plank are bolted to the flange of the condenser and may be set at any elevation. The seat and foot rest are made in one piece and can be moved along the plank to the most convenient position. A $^3/_4$-in. quick-opening gate valve is supported from the foot rest and is controlled by the operator's foot. Large condensers are cleaned without taking the heads off; this eliminates the seat and foot support, and the $^3/_4$-in. valve is then located adjacent to the nozzle and is operated by hand.

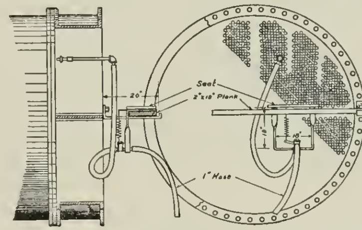

Fig. 8 Arrangement of Equipment for Cleaning Condenser by Rubber Plugs or Scrapers (Head Removed)

The author does not believe in the efficiency of providing valve in the intake and discharge line of the condenser in order to reverse the flow of the water.

The ejector method applying low-pressure water and air at 80 lb. pressure to the tubes is illustrated in Fig. 9. The equipment consists of a $^3/_4$-in. tee into which the $^1/_4$-in. air nozzle A is inserted, thus forming an ejector. Nozzle N is flattened out so as to impart a spiral flow to the water. The air connection is made tc point A

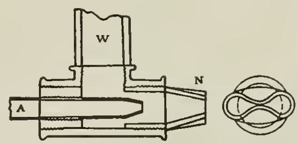

Fig. 9 Ejector for Applying Low-Pressure Water to Condenser Tubes by Compressed Air

and the water connection is made at W, using water at atmospheric pressure. It requires about five seconds to clean each tube properly with this method. (*The Electric Journal*, vol. 18, no. 7, July 1921, pp. 313–315, 6 figs. *d*)

Removing Scale from Surface-Condenser Tubes with Hydrochloric Acid, Norman G. Hardy. Date obtained from the practice of the Arizona Copper Co., at Clifton, Ariz., where hydrochloric acid has been used to clean condensers for the last two years. It is not claimed that this method is entirely satisfactory or that it is suitable under all conditions, but it has given very good success at the plant.

The general arrangement of apparatus is shown diagrammatically in Fig. 10. The condensers in this outfit have a tube area of 7600 sq. ft. in 2500 Muntz metal tubes $^3/_4$ in. in diameter by 15 ft. 1 in. long. The condensers have two passes with a vertical diaphragm between the water inlet and outlet compartments.

Before using the acid, both heads are removed from the water boxes, the tubes are washed out with a hoset he scale is cleaned from the water boxes, theheads, and, so far as,practicable, from the tubes sheets also; after drying thoroughly, water boxes, heads and tube sheets are painted with two coats of roofing cement, to eliminate all chances of corrosion of the permanent parts of the condenser.

At first an acid-proof paint was tried, with the idea of maintaining a coating that would only have to be replaced occasionally, but it was found that the coating would not remain serviceable from one cleaning to the next. After trying several asphaltic paints, it

was decided that roofing cement, such as is ordinarily supplied for cementing the seams of prepared roofing, was best because it is sufficiently acid-resistant, can be easily applied, and dries quickly.

Cover plates with gaskets are next fastened over water inlet and outlet with capscrews tapped into the water box. The heads are then replaced and the apparatus connected up as indicated in the figure.

Vent pipes about 12 ft. long are placed at the top of each water compartment. The water boxes are tapped for $1^1/_2$-in. pipe and have a short nipple and reducer to connect to the 3-in. vent pipe. These vent pipes are very necessary, and it has been found that gas will blow water over if a height of less than 12 ft. is used. To circulate the solution, a 2-in. brass centrifugal pump with direct-connected motor drive is used.

The acid used is commercial hydrochloric, averaging about 24 per cent HCl. It is estimated that the water boxes and tubes will hold 7800 lb. of water, and 1000 lb. of acid is used for cleaning, making the solution about 3 per cent HCl. A stream from a $^3/_4$-in.

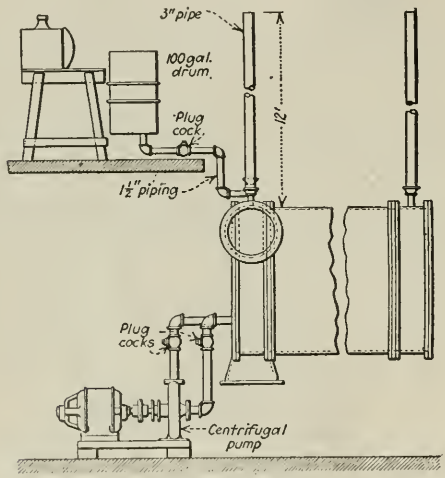

Fig. 10 Arrangement of Apparatus for Cleaning Condenser with Hydrochloric Acid

hose is used for supplying water and the time required to discharge a measured quantity to the mixing tank is noted. From this the length of time necessary to empty one carboy of acid, with water flowing into the tank continuously, is calculated. Having the outlet from the mixing tank open, the water from the hose and the acid from the carboy are delivered into the mixing tank at a predetermined rate, whence they flow into the condenser continuously until it is filled. This is a rather crude method of proportioning the mixture, but it has been satisfactory in practice.

As soon as the level of the solution in the condenser rises above the pump suction, the pump is started. It is kept running for four to five hours, by which time the acid is entirely neutralized. The solution is usually not drained from the condenser until the following day.

The amount of scale actually dissolved is relatively small, being equivalent to a thickness of about 0.001 in. for the condenser and mixture described. But the great benefit of acid treatment is that it softens and loosens scale, so that it can easily be removed by washing and brushing. For this reason, if the condenser is very dirty, it will probably be more economical to treat it several times with a weak solution, washing out the loosened material between treatments, than to use a stronger solution.

The principal objections to the use of acid for cleaning are high cost and the possibility of injury to tubes and packing. The first of these is undoubtedly justified and eliminates this method in any case where the tubes are in good condition and the scale is not too hard to permit mechanical cleaning.

With regard to the second objection, it can be positively stated that the experience of the Arizona Power Co., Ltd. for two years past does not indicate any serious deterioration of tubes as a result of the use of acid for cleaning. (*Power*, vol. 54, no. 1, July 5, 1921, pp. 22–24, 1 fig., *b*)

SPECIAL PROCESSES (See Machine Shop)

Charcoal-Iron Boiler Tubes

The Manufacture of Charcoal-Iron Boiler Tubes. Description of the processes employed by the Parkesburg Iron Co., Parkesburg, Pa. The processes are of interest, partly because of the considerable use of this kind of tubes and also because of the fact that the manufacture has been to an unusually slight degree affected by the general processes of mechanization of modern industry.

The first stage in manufacture is selection of scrap to go into the melt. Metal containing copper, tin, nickel, chromium or more than one-half of one per cent silicon is considered to be unfit for use, as these elements tend to make he finished product dry or brittle and unweldable.

The charges, in not more than 300-lb. lots, are placed in small forge fires in furnaces which to all intents and purposes have not changed in design in the last thousand years. In a rectangular hearth about 16 in. deep by 2 ft. square with a cast-iron box about 3 ft. high and open in the front, the charges are slowly melted in incandescent charcoal, the required oxygen being furnished by a blast of air entering the charcoal bed at an angle at about half its depth. Under the action of the blast the light scrap begins to melt and during the heating the impurities such as carbon, manganese, silicon and sulphur are slowly oxidized, a relatively large proportion of iron also undergoing the same process. The oxides unite to form a high basic slag with a comparatively low melting point and therefore quite fluid.

Gradually the mass becomes a conglomeration of microscopic grains of pure plastic iron, each covered or glazed with a film of slag.

The incandescent lump is then removed to a steam hammer where it is forged or "shingled" to a bloom about 30 in. by 5 in. by 6 in. Before it is placed under the hammer the lump resembles a sponge with the holes filled with molten slag, and the whole covered with a husk of iron oxide and partly consumed charcoal. Under the hammer most of the slag between the grains of the iron is forced out. From the hammers the hot blooms are passed to a reheating furnace and then rolled into bars. In this process the balance of the slag is almost entirely worked out.

After cooling, the bars are sheared into the required length, reheated and rerolled in a two-high plate mill. The rolling is done transversely, that is, the length of the pile is parallel with the axis of the rolls. The pile is run through the mill until the length of the resulting slab is equal to the desired width of the finished plate. The slab is then turned through 90 deg. and rolled for length and thickness to give the iron cross fiber or additional strength across the grain. The metal is always rolled in the same direction, and the few impurities left are worked to one end of the plate, which is cropped off and a much better surface is obtained.

The plates are next trimmed into strips of the proper width to make the tubes ("skelp").

The rest of the operations do not materially differ from the manufacture of welded tubing of other kinds. (*The Boiler Maker*, vol. 21, no. 7, July 1921, pp. 187–190 and 212, 9 figs., *d*).

STEAM ENGINEERING (See Power Plants)

CLASSIFICATION OF ARTICLES

Articles appearing in the Survey are classified as *c* comparative; *d* descriptive; *e* experimental; *g* general; *h* historical; *m* mathematical; *p* practical; *s* statistical; *t* theoretical. Articles of especial merit are rated *A* by the reviewer. Opinions expressed are those of the reviewer, not of the Society. The Editor will be pleased to receive inquiries for further information in connection with articles reported in the Survey.

ENGINEERING RESEARCH

A Department Conducted by the Research Committee of the A.S.M.E.

Engineering Research at Michigan

THE report of Prof. A. E. White, Director of the Department of Engineering Research at the University of Michigan, made to the third meeting of the Executive Committee of the Advisory Board, outlines the plans of the department. The report shows the great value of the industrial products of Michigan and comments on the work done at the Mellon Institute, the M.I.T. and the University of Illinois, and from this points out the opportunity for development of the department of research at the University. The department has an Advisory Board of one hundred men made up of the leading business men of the state and divided into groups according to the industries to which they belong. These subdivisions will be called Committees, and the chairman of each Committee will be empowered to enlarge the Committee when necessary. These sub-committees will confer with the Director of the Department of Engineering Research on problems and policies and on the methods of solving various research problems. The University has placed all of its facilities at the service of the Department of Engineering Research.

The method of financing various research investigations has not been decided on. Six plans are suggested:

1 All cost of investigation cared for by interested parties
2 Investigations financed from income from the state
3 Investigations financed from funds of an association formed for this purpose
4 Joint financing: industries provide funds, state provides building
5 Joint financing: industries provide building, state provides endowment
6 Industries provide buildings and endowments.

Locomotive Testing

The Locomotive Testing Laboratory of the University of Illinois is one of the largest laboratories for this purpose and in some respects the best-equipped locomotive laboratory in existence. The expense of operating it, however, is great, and for that reason little work is being done. It is hoped that steps may be taken by certain railway interests to use the laboratory for the purpose of research regarding the action of locomotives. It is believed that the authorities of the University of Illinois are willing to donate the use of the laboratory provided interested parties would finance the maintenance of the Research Staff and the purchase of coal and necessary supplies. This cost would amount to $60,000 per year, exclusive of any rental which might be charged the company furnishing the locomotive for test. The use of this laboratory for an investigation of locomotive problems would probably lead to extensive savings in the use of coal and other supplies. Address Dean C. R. Richards, University of Illinois, Urbana, Ill.

Research Résumé of the Month

A—Research Results

The purpose of this section of Engineering Research is to give the origin of research information which has been completed, to give a résumé of research results with formulas or curves where such may be readily given, and to report results of non-extensive researches which, in the opinion of the investigators, do not warrant a paper.

Apparatus and Instruments A7–21. Hygrometer. Technical Note 148 of the Forest Products Laboratory is on the Care and Use of Hygrometer in Kiln Drying. The note states that each thermometer of the hygrometer should be compared with the standard thermometer before using and a record noted. The hygrometer reservoir should be filled with pure water only. It is important that the silk or muslin covering of the wet bulb be kept in good condition at all times. A small amount of solid material is always left in the meshes after evaporation and this impedes distribution of moisture. The hygrometer should be placed at the exact points at which information is desired. Do not place it near door, wall or radiator. Such positions are not representative. In reading wet bulb sufficient air circulation should be present to give maximum evaporative rate from covering. U. S. Forest Products Laboratory, Madison, Wis. Address Director.

Automotive Vehicles and Equipment A7–21. Brake Linings. An investigation on commercial brake linings is being made at the Bureau of Standards and the results of these tests will be published later. One of the preliminary results shows that the coefficient of friction between the brake band and drum may fall to one-third of its normal value when the brakes first become hot. On cooling the normal value is restored. Used linings do not show this effect to such a great extent. Bureau of Standards, Washington, D. C. Address S. W. Stratton, Director.

Economics A1–21. Telephone Service. Circular 112 of the Bureau of Standards on Telephone Service has just been published and may be obtained at 65 cents per copy from the Superintendent of Documents. This circular describes the service which the telephone company sells, enumerating the elements of the service and how the grade of service is dependent on each. It describes the various instruments used and calls attention to what determines the grade of service furnished by various companies. It describes the regulatory commissions controlling telephone service and discusses the matter of plant extensions, abandonment of service, physical connections, accounting, valuation, rates, contracts, collections and discriminations, etc., etc. Bureau of Standards, Washington, D. C. Address S. W. Stratton, Director.

Electrical Communication A1–21. Telephone Service. See *Economics A1–21.*

Fuels, Gas, Tar and Coke A12–21. Sulphur in Coal. The Analysis of the Sulphur Forms in Coal is the subject of Technical Paper 254 by Alfred R. Powell for the Bureau of Mines. The purpose of the paper was to test the method of Powell and Parr for the analysis of sulphur forms in coal, to determine its application and to indicate, if necessary, certain refinements in the process. The Powell and Parr method is described and the investigation proves it to give correct and accurate results and that dilute nitric acid will extract small amounts of organic sulphur from certain coals. This is in the unstable phenol-soluble form. In order to avoid this error it is recommended that pyritic sulphur be calculated from the pyritic iron value. The results show that acid extractions can be materially shortened by a shaking machine and that dilute nitric acid not only extracts the pyrites quantitatively but also the same iron and sulphur taken into solution by dilute hydrochloric acid. Hence dilute nitric acid extraction need not be extracted first with hydrochloric acid. The experiments showed that semi-bituminous coals and harder bituminous coals must be digested a long time with concentrated nitric acid before the organic matter will become completely soluble in ammonia. The research proved that the Eschka method is preferable to the sodium peroxide method for the analysis of sulphur in coal and the coal residue, unless the sodium peroxide used has a low and constant sulphur content. Bureau of Mines, Washington, D. C. Address H. Foster Bain, Director.

Heat A11–21. Constants of Transmission for Pipe Covering at High Temperature Differences. One of the thesis subjects at the Rensselaer Polytechnic Institute during the spring of 1921 was the investigation of pipe covering of the Philip Carey Company of Cincinnati. Three types were tested: Carey Carocel, consisting of numerous laminations corrugated longitudinally with about ten layers per inch; Carey Multiply, a laminated covering made up of numerous rough-surfaced asbestos sheets of about 32 layers per inch, and Carey 85 per cent Magnesia. These coverings were tested in single, double and triple thicknesses—approximately 1 in., 2 in. and 3 in. The constant k of transmission was computed from the formula—

$$\text{Heat} = k2\pi L(t_1 - t_2)/\log_e(r_2/r_1)$$

in which L = length in feet, $(t_1 - t_2)$ = temperature difference in deg. fahr., and r_2 and r_1 are respectively the radii to the outside and inside of covering.

The results of the tests are shown in Figs. 1 and 2. Fig. 1 indicates that in general the coefficient of heat transfer increases with the temperature difference in 1-in. covering, and as the thickness of the covering increases the coefficient remains more nearly constant. The variations of the coefficient with thickness of covering at temperature differences of 200 deg. and of 600 deg. are indicated in Fig. 2. Rensselaer Polytechnic Institute, Troy, N. Y. Address Arthur M. Greene, Jr.

Heat A12–21. Heat Transfer to Oil. The Coefficient of Heat Transfer from Steam to Oil through Steel Pipe has been the subject of a thesis at the Rensselaer Polytechnic Institute. The results of this thesis

are shown in the curves of Fig. 3. The oils used were as follows:

450 Red—Kendall Refining Company.
- Specific gravity........ 31 deg. B.
- Viscosity.............. 181 Saybolt at 100 deg. fahr.
- Flash point............ 356 deg. fahr.
- Burning point......... 451 deg. fahr.

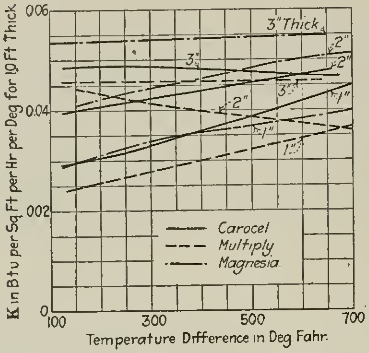

Fig. 1 Variation of Coefficient of Heat Transfer with Temperature Difference

600 Cylinder—Kendall Refining Company
- Specific gravity........ 25.5 deg. B.
- Viscosity.............. 95 Saybolt at 212 deg. fahr.
- Flash point............ 428 deg. fahr.
- Burning point......... 550 deg. fahr.

Kerosene—Commercial Kerosene of the Standard Oil Company

28–30 Petroleum Fuel Oil—Standard Oil Company
- Specific gravity........ 30.8 deg. B.
- Viscosity.............. 51 Saybolt at 100 deg. fahr.
- Flash point............ 205 deg. fahr.
- Burning point......... 300 deg. fahr.

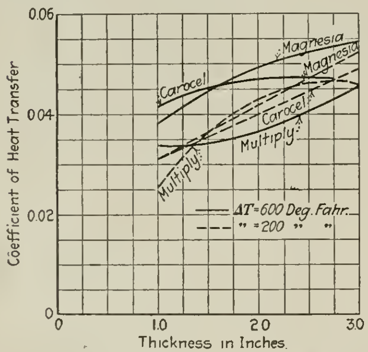

Fig. 2 Variation of Coefficient of Heat Transfer with Thickness of Covering at Temperature Differences of 200 and 600 Deg. Fahr.

Crude Oil—Standard Oil Company
- Specific gravity........ 33.4 deg. B.
- Viscosity.............. 53 Saybolt at 100 deg. fahr.
- Flash point............ 110 deg. fahr.
- Burning point......... 136 deg. fahr.

The 14–16 fuel oil was not tested for physical properties. Rensselaer Polytechnic Institute, Troy, N. Y. Address Arthur M. Greene, Jr.

Illumination A1–21. Prof. E. H. Waldo has investigated the distribution of incandescent street-lighting units and has found that the statements issued by the various companies producing the units are substantially correct. Address Dean C. R. Richards, Engineering Experiment Station University of Illinois, Urbana, Ill.

Internal-Combustion Motors A3–21. Water Injection with Kerosene as Fuel. One of the undergraduate theses at the Rensselaer Polytechnic Institute during the spring of 1921 has been the investigation of effect of injecting water with kerosene in an internal-combustion engine. The engine used was a 7-in. by 12-in. Fairbanks-Morse type horizontal gas engine fitted for various types of fuel. Water was allowed to enter with the kerosene and both the water and kerosene were preheated to 150 deg. fahr. by passing them through an iron tube heated by a bunsen burner. In all cases the amount of water injected was computed as that above the moisture in the air at 5.8 grains per cu. ft. The effect of the water injection is to reduce the initial explosion pressure and at full load the injection of water seems to decrease the fuel consumption. The decrease of explosion pressure increases the smoothness of operation of the engine and this seems to increase mechanical efficiency of the engine by giving greater pressures at more advantageous crank angles. At great quantities of water injection the mechanical efficiency decreases, and this is believed to be due to the tendency of the water to destroy the cylinder lubrication. Water injection seems to result in a cooler operation of the engine, as shown by the decrease in the amount of heat absorbed by the cooling water and the lower temperature of the exhaust gases. Fig. 4 shows the pounds of fuel per brake horsepower-hour at different ratios of kerosene to water, the curves indicating that 8 lb. of kerosene to 1 lb. of water gives the best result. Fig. 5 shows the effect of various amounts of water injected at different horsepowers. Fig. 6 shows the effect of water injection on the initial explosion pressure and Fig. 7 the effect of water injection on the mechanical efficiency. Rensselaer Polytechnic Institute, Troy, N. Y. Address Arthur M. Greene, Jr.

Metallurgy and Metallography A12–21. Centrifugally Cast Steel. Technologic Paper No. 192 of the Bureau of Standards dealing with centrifugally cast steel has just been issued. It may be obtained from the Superintendent of Documents, Washington, D. C. at 10 cents a copy. The experiments reported show that metal so cast shows physical soundness and freedom from chemical segregation. For certain shapes forging and boring operations may be eliminated. It is shown that subsequent heat treatment of such castings improves them and makes them comparable with forgings. Bureau of Standards, Washington, D. C. Address S. W. Stratton, Director.

Metallurgy and Metallography A13–21. Corrosion of Soft Metals. The results of the investigation of corrosion will soon be published. The investigation has determined the extent of intercrystalline embrittlement of soft metals—zinc, aluminum and tin—as a result of prolonged corrosion. Lead has been previously studied. Although the effect of stress in accelerating this action in lead will be studied, the publication of the results is expected at an early date. Bureau of Standards, Washington, D. C. Address S. W. Stratton, Director.

Mining, General A4–21. Gas Masks. Gas Masks for Gases Met in Fighting Fires is the subject of Technical Paper 248 issued by the Bureau of Mines. It is prepared by A. C. Fieldner, S. H. Katz and S. P. Kinney. It also contains a chapter on the Effects of Gases and the Treatment of Gas Poisoning by Y. Henderson. Bureau of Mines, Washington, D. C. Address H. Foster Bain, Director.

Mining, General A5–21. Safety Lamps. The Relative Safety of Brass, Copper and Steel Gauze in Safety Lamps is the subject of Technical Paper 228 of the Bureau of Mines by L. C. Ilsley and A. B. Hooker. The pamphlet describes the method of mixing the gas and air, the construction of the flame-testing galley, the method of mixing and the condition of the gauze at different times. The investigation includes:

1 Study of European reports on similar research
2 A selection of critical tests for a publication on safety
3 Obtaining enough material to duplicate such tests
4 The performance of check tests
5 A report and analysis of results.

The investigation checked the results obtained by Belgian investigators. For conditions of high temperatures steel proved superior to brass or copper, while at low temperatures the different materials were about equal. Brass proved more satisfactory than copper. The least safe lamp of all tested was the single-gauze unbonneted lamp of the Davy type. The double-gauze unbonneted lamp is safer than a single-gauze lamp. The bonneted lamps were better than unbonneted lamps, the bonnet being more effective than an additional gauze. The safest lamp was the double-gauze bonneted lamp. The results indicate

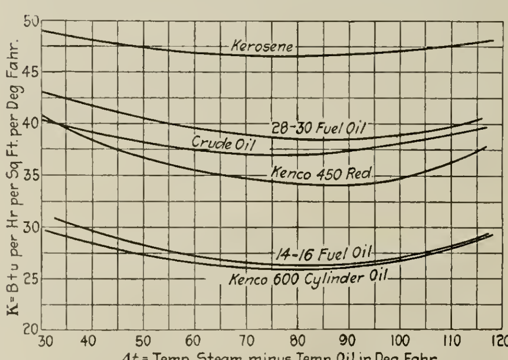

Fig. 3 Coefficient of Heat Transfer from Steam to Oil through Steel Pipe

that the present specification of Schedule No. 7 is not detailed enough. Bureau of Mines, Washington, D. C. Address H. Foster Bain, Director.

Petroleum, Asphalt and Wood Products A5–21. Bulletin 194 of the Bureau of Mines is devoted to some principles covering the production of oil wells. It is prepared by Carl H. Beal and J. O. Lewis. The bulletin describes the factors controlling the production such as the oil content of the ground, the ultimate production, the factors governing the decline of oil wells, the declining production of an oil property, the consideration of flush and settled production, and the life of oil wells. In addition the bulletin gives the publications on petroleum technology issued by the Bureau of Mines. Bureau of Mines, Washington, D. C. Address H. Foster Bain, Director.

Petroleum, Asphalt and Wood Products A6–21. UNDERGROUND CONDITIONS IN OIL FIELDS. Bulletin 195 on the Underground Conditions in Oil Fields by A. W. Ambrose is a publication of 238 pages. Its purpose is to point out the general method of procedure in studying underground conditions and to place before the petroleum industry the results of proper coöperation between the technical man and practical man. The bulletin would also serve as a guide to the engineer in solving oil-field problems and indicate to him studies that should be made in oil-field development. The bulletin is illustrated with charts, diagrams and halftones. Bureau of Mines, Washington, D. C. Address H. Foster Bain, Director.

Wood Products A5–21. WOOD RESEARCH. The Forest Products Laboratory has recently issued Technical Note 150 on the Effect of Direction of Fibers on the Strength of Fiber Boxes. Technical Note 151 on the Cause and Prevention of Blue Stains in Wood and Technical Note 152 on the Antiseptic Treatment of Wood Pulp to Prevent Mold and Decay. U. S. Forest Products Laboratory, Madison, Wis. Address Director.

B—RESEARCH IN PROGRESS

The purpose of this section of Engineering Research is to bring together those who are working on the same problem for coöperation or conference, to prevent unnecessary duplication of work and to inform the profession of the investigators who are engaged upon research problems. The addresses of these investigators are given for the purpose of correspondence.

Explosives and Explosions B1–21. GASEOUS MIXTURES. See *Internal-Combustion Motors B8–21.*

Frame Structures B1–21. INDETERMINATE STRUCTURES. A classification is being made of the source material on the subject of analysis of stresses in statically indeterminate structures which were published in Bulletin No. 108 of the Engineering Experiment Station, University of Illinois. The purpose of the research is to put the material in form for use by practical engineers. Address Dean C. R. Richards, Engineering Experiment Station, University of Illinois, Urbana, Ill.

Fuels, Gas, Tar and Coke B2–21. BREAKAGE OF COAL. Prof. H. H. Stoek and Messrs. L. R. Nylius and H. H. Huang are determining the breakage of different coals when dropped from different heights. Circular 6 of the Engineering Experiment Station discusses the apparatus used.

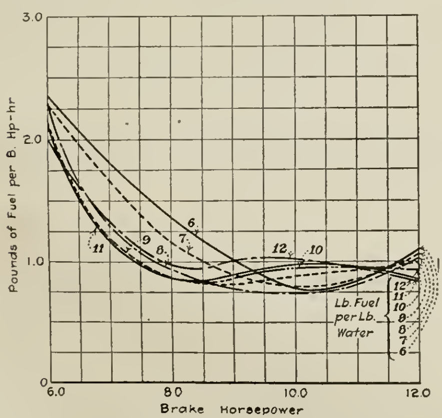

FIG. 4 FUEL REQUIRED PER BRAKE HORSEPOWER-HOUR AT VARIOUS RATIOS OF KEROSENE TO INJECTION WATER

See page 125. Address Dean C. R. Richards, Engineering Experiment Station, University of Illinois, Urbana, Ill.

Internal-Combustion Motors B7–21. IGNITION. A study of the electrical ignition systems for gasoline engines is being made under the direction of Prof. E. P. Payne by Mr. Y. Naito and others for the purpose of determining the relative amounts of energy delivered by sparks from various systems. The heat energy is being determined by a special calorimeter and the electrical phenomena are being determined by means of oscillograph records. Address Dean C. R. Richards, Engineering Experiment Station, University of Illinois, Urbana, Ill.

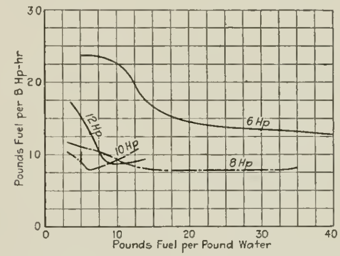

FIG. 5 RELATION BETWEEN FUEL CONSUMPTION PER B.HP-HR. AND RATIO OF FUEL TO INJECTION WATER

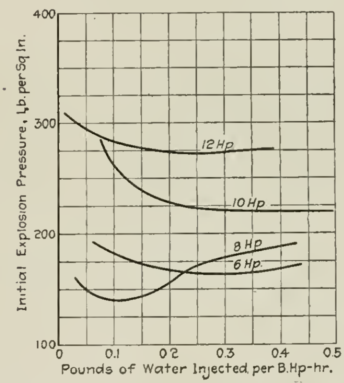

FIG. 6 VARIATION OF INITIAL EXPLOSION PRESSURE WITH AMOUNT OF WATER INJECTED

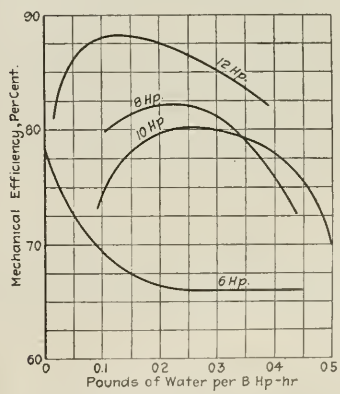

FIG. 7 VARIATION OF MECHANICAL EFFICIENCY WITH AMOUNT OF WATER INJECTED

Internal-Combustion Motors B8–21. EXPLOSION OF GASEOUS MIXTURES. Prof. A. P. Kratz and Mr. C. Z. Rosecrans are investigating the effect of shape of cylinder head, position of ignition plug and the effect of agitation of the gases upon the maximum pressure produced by explosion and on the time of explosion of gaseous mixtures. The pressure is measured by a specially designed diaphragm indicator making use of a spot of light, and time is determined by comparison with a photographic record made by a mirror on a tuning fork. Address Dean C. R. Richards, Engineering Experiment Station, University of Illinois, Urbana, Ill.

Internal-Combustion Motors B9–21. Internal Phenomena. An analysis of the thermal and chemical phenomena occurring in the cylinder of an internal-combustion engine is being made by Prof. G. A. Goodenough and Messrs. C. T. Felback and C. Z. Rosecrans. This work is almost complete. Address C. R. Richards, Engineering Experiment Station, University of Illinois, Urbana, Ill.

Machine Design B4–21. Riveted Joints. Prof. W. M. Wilson is investigating riveted joints subject to reverse stresses for the purpose of determining suitable working stresses for rivets and such joints and to determine the relative merits of different methods of driving rivets. Address Dean C. R. Richards, Engineering Experiment Station, University of Illinois, Urbana, Ill.

Machine Tools B3–21. Gear Measurements. Representatives of the Bureau of Standards have visited a number of gear manufacturers to obtain information as to the requirements of testing and measuring gears, cutters and hobs. A machine is now being designed to measure the important elements of gears and gear-cutting tools. Bureau of Standards, Washington, D. C. Address S. W. Stratton, Director.

Mechanics B1–21. Pressure Through Granular Materials. Mr. L. M. Enger is determining the bearing pressure which granular materials will sustain under various conditions of size, angularity and restraint. Address Dean C. R. Richards, Engineering Experiment Station, University of Illinois, Urbana, Ill.

Mechanics B2–21. Rapid Loading. The strength and ductility of steel under rapid loading is being investigated by Prof. H. F. Moore. Address Dean C. R. Richards, Engineering Experiment Station, University of Illinois, Urbana, Ill.

Mechanics B3–21. Boiler Heads. The stresses produced in forming boiler heads are being examined by Prof. H. F. Moore in studying the effect of the rapid application of a load produced by the fall of a heavy weight. Address C. R. Richards, Engineering Experiment Station, University of Illinois, Urbana, Ill.

Metallurgy and Metallography B10–21. Tempering of Hardened Steels. The Bureau of Standards is continuing the work on this subject in the Metallurgical Division. The investigation deals with micro changes which occur during tempering. Bureau of Standards, Washington, D. C. Address S. W. Stratton, Director.

Railway Rolling Stock and Accessories B2–21. Timber for Freight-Car Construction. For the antiseptic treatment of timber used in freight-car construction, see *Wood Products B2–21.*

Steam Power B1–21. Air-Steam Mixtures. Dean C. R. Richards and Mr. L. A. Wilson are investigating the thermal efficiencies of a small Corliss engine using various mixtures of compressed air and steam, the quantity of air being determined by a venturi meter and the amount of steam being determined by condensation. Address Dean C. R. Richards, Engineering Experiment Station, University of Illinois, Urbana, Ill.

Ventilation B1–21. Friction and Power Loss. Prof. A. C. Willard and others are preparing to investigate the friction and power requirements for supplying and exhausting air from the projected vehicular tunnels under the Hudson River. The air ducts in this case will be made of concrete with concrete elbows. The air discharge will be uniform from the side of the experimental duct. Address Dean C. R. Richards, Engineering Experiment Station, University of Illinois, Urbana, Ill.

Wood Products B2–21. Freight-Car Floor Timbers. The antiseptic treatment of timber used in freight-car construction is the subject of a research to determine the best commercial method therefor. Open-tank and brush methods of treatment on air-dried timber have been tested after cutting to dimensions. Tongue-and-groove joints, lap joints and common joints have been used with each type of treatment. Floors are assembled and placed in a position exposed to the weather. Address Dean C. R. Richards, Engineering Experiment Station, University of Illinois, Urbana, Ill.

C—Research Problems

The purpose of this section of Engineering Research is to bring together persons who desire coöperation in research work or to bring together those who have problems and no equipment with those who are equipped to carry on research. It is hoped that those desiring coöperation or aid will state problems for publication in this section.

D—Research Equipment

The purpose of this section of Engineering Research is to give in concise form notes regarding the equipment of laboratories for mutual information and for the purpose of informing the profession of the equipment in various laboratories so that persons desiring to conduct special investigations may know where such work may be done.

Aircraft D1–21. Large Wind Tunnel. See *Apparatus and Instruments D1–21.*

Apparatus and Instruments D1–21. Large Wind Tunnel. The Aerodynamics Section of the Bureau of Standards is constructing a new tunnel 10 ft. in diameter. This will give exceptional facilities to all types of research work involving the study of the behavior of objects in a wind stream. Bureau of Standards, Washington, D. C. Address S. W. Stratton, Director.

University of Arizona D1–21. The Mechanical Laboratory is provided with the following equipment:

- 75-hp. internally fired boiler and accessories
- A small vertical boiler
- Three high-speed engines, gasoline engine and automobile motor
- Pelton wheel
- Turbo-blower
- A single-stage and double-stage centrifugal pump
- Duplex direct-acting steam pumps and instruments for testing and calibration.

The power plant of the University is also used for a mechanical laboratory. Address Professor A. J. Wiechardt, University of Arizona, Tucson, Ariz.

University of California D1–21. The following equipment at the University of California is modern, dating from 1916. The equipment is noted under various Experiment Stations at which certain experiments are performed:

General:

Experiment Stations 100 to 109. Comprising calibration apparatus for thermometers, pyrometers, gages; lubricators; indicator and manograph study; valve, valve-gear and governor study from one simple and one Stephenson link compound engine; measurements of gases; measurements of vapors; orifices; measurement of power by prony brake, belt dynamometer, water brake, Sprague dynamometer, etc.

Fuels and Oils:

Experiment Stations 200 to 205. Comprising gas photometry; fuel calorimetry on the Parr, Junker and Hempel apparatus; fuel analysis; gas analysis; testing of lubricating oils.

Air:

Experiment Stations 300 to 305. Comprising Ingersoll-Rand compressor tests with variable-speed motor drive and belt dynamometer; Rider-Ericsson hot-air engine tests.

Internal-Combustion Engines:

Experiment Stations 400 to 406. Comprising tests on Continental motor, Ferro gas engine, Willys-Knight sleeve-valve engine, semi-Diesel engine, Westinghouse gas engine, Standard gas engine, Sprague dynamometer, etc.

Automotive Equipment:

Experiment Stations 500 to 514. Comprising work on Ford chassis; Willys-Knight sectional model; "Cut-away" chassis showing every moving part of a standard slide-gear car; magnetic gear shift; caterpillar tractor; Weidley engine; Buick engine; battery ignition systems; magnetos; rectifiers; Sprague dynamometer tests of generators and of starters; carburetors; also in the official headlight testing laboratory of the State of California which is located in the building.

Steam:

Experiment Stations 600 to 610. Comprising steam calorimetry; study of steam auxiliaries such as traps, separators, valves, boiler-feed apparatus and boiler-feed-heating equipment; tests of steam pumps; injectors; tests on Ideal marine compound engines; complete tests of a Curtis turbo-generator; complete boiler test; complete power-plant test; study of section models of a Curtis 30-hp. turbine, of a Curtis 500-kw. turbine and of a 3000-kw. Westinghouse Parsons turbine.

E—Research Personnel

The purpose of this section of Engineering Research is to give notes of a personal nature regarding the personnel of various laboratories, methods of procedure for commercial work or notes regarding the conduct of various laboratories.

F—Bibliographies

The purpose of this section of Engineering Research is to inform the profession and especially the members of the A.S.M.E. of bibliographies which have been prepared. These bibliographies have been prepared at the request of members, and where the bibliography is not extensive, this is done at the expense of the Society. For bibliographies of a general nature the Society is prepared to make extensive bibliographies at the expense of the Society on the approval of the Research Committee. After these bibliographies are prepared they are loaned to the person requesting them for a period of one month. Additional copies are prepared which are available for periods of two weeks to members of the A.S.M.E. or to others recommended by members of the A.S.M.E. These bibliographies are on file in the offices of the Society and are to be loaned on request. The bibliographies are prepared by the staff of the Library of the United Engineering Society which is probably the largest engineering library in this country.

THE Boiler Code Committee meets monthly for the purpose of considering communications relative to the Boiler Code. Any one desiring information as to the application of the Code is requested to communicate with the Secretary of the Committee, Mr. C. W. Obert, 29 West 39th St., New York, N. Y.

The procedure of the Committee in handling the cases is as follows: All inquiries must be in written form before they are accepted for consideration. Copies are sent by the Secretary of the Committee to all of the members of the Committee. The interpretation, in the form of a reply, is then prepared by the Committee and passed upon at a regular meeting of the Committee. This interpretation is later submitted to the Council of the Society for approval after which it is issued to the inquirer and simultaneously published in MECHANICAL ENGINEERING.

Below are given the interpretations of the Committee in Cases Nos. 351 to 356 inclusive, as formulated at the meeting of May 12, 1921, and approved by the Council. In accordance with the Committee's practice, the names of inquirers have been omitted.

CASE NO. 351

Inquiry: Is it necessary, under Par. 2 of the Boiler Code, that welded or seamless circular furnaces or flues in boilers up to 18 in. in diameter as specified in Par. 241, must conform to the requirements for firebox plate material when exposed to the products of combustion?

Reply: It is not necessary that welded or seamless circular furnaces or flues up to 18 in. in diameter meet the specifications for boiler plate material. It is the opinion of the Committee that such boiler parts should be constructed from material fulfilling the requirements for lap-welded and seamless boiler tubes given in Par. 165 of the Boiler Code.

CASE NO. 352

Inquiry: Is it not permissible to construct boilers of the locomotive, economic or other portable types as coming under the classification of traction or portable boilers, as regards the attachment of lugs or brackets for which Par. 325 of the Boiler Code permits the use of studs with pipe threads? It is found impossible to properly rivet the lugs on certain designs of locomotive-type boilers where the lugs are to be located near the bottom of the waterleg of the firebox.

Reply: It is the opinion of the Committee that where the boilers of the portable type are to be fitted with lugs or brackets, the practice specified in the last sentence of Par. 325, of using studs, is permissible.

CASE NO. 353

Inquiry: Is it permissible, under the requirements of Par. 218 of the Boiler Code, to use stay tubes in place of through stays for supporting the surfaces around the manhole in the heads of h.r.t. boilers?

Reply: Stay tubes are not permissible for supporting the surfaces around the manhole in the heads of h.r.t. boilers.

CASE NO. 354

Inquiry: What are the requirements of the Heating Boiler Section of the Code, relative to the staying of flat surfaces of steel heating boilers designed to operate at a pressure not to exceed 15 lb. per sq. in.?

Reply: Par. 372 of the Code specifies a shop test of 60 lb. per sq. in. hydrostatic pressure shall be applied to steel or cast-iron boilers used exclusively for low-pressure steam heating. It is the opinion of the committee that in staybolting a boiler of this sort, the stresses in the material should not exceed those allowable in power boiler practice which would necessitate computing the staybolts and their spacing for a working pressure of at least 40 lb. per sq. in., or two-thirds of the test pressure.

CASE NO. 355

(In the hands of the Committee)

CASE NO. 356

Inquiry: Is a boiler constructed as shown in the prints and described, safer under the Boiler Code Rules than other forms of similar boilers?

Reply: The Boiler Code Committee does not express opinions upon the relative merits of different designs of boilers. This is in accordance with the Constitution of the Society, C56 of which reads as follows:

> C56 The Society shall not endorse any commercial enterprise. It shall not allow its imprint or name to be used in any commercial work or business.

An interpretation of the Boiler Code is a proper action of the Boiler Code Committee and will always be given upon request.

"The A.S.M.E. Code Boilers"

The A.S.M.E. Boiler Code Committee has been apprised of the fact that several boiler manufacturers are following the practice of referring to boilers built to conform to the requirements of the A.S.M.E. Boiler Code as "A.S.M.E. Boilers." In fact, advertisements in the trade papers have actually appeared in which Code boilers are referred to in that form.

Inasmuch as this practice is erroneous and incorrect, the Boiler Code Committee suggests that manufacturers state that their boilers are built in accordance with the Boiler Code of The American Society of Mechanical Engineers, or should the manufacturers or any one else desire to refer to such boilers in a briefer way, that they designate them as "A.S.M.E. Code Boilers."

CORRESPONDENCE

CONTRIBUTIONS to the Correspondence Department of MECHANICAL ENGINEERING are solicited. Contributions particularly welcomed are discussions of papers published in this Journal, brief articles of current interest to mechanical engineers, or suggestions from members of The American Society of Mechanical Engineers as to a better conduct of A.S.M.E. affairs.

Appraisal Methods

TO THE EDITOR:

Appraisal and the determination of annual depreciation, which is an inseparable part of it, has until recently been almost wholly in the hands of accountants, but the recent problems involving capitalization which have been made an important issue on account of the income and excess-profits tax, have brought the engineer into the problem, so that at the present time we have two general methods of procedure in appraisals, i.e., the accounting method and the engineering method. The faults and weaknesses of the first are simple and easily exposed, but the weakness and liability to error of the engineering method, involving as it does the personal factor, are likely to be hidden in a mass of varying opinions.

The accountants' method consists in assuming a more or less correct total life of the property, and marking off an annual depreciation on a straight-line, logarithmic or some other purely mathematical basis. In prewar days this method, with a large factor of safety in the annual rate, was safe if not sound. It resulted in the extinction of values—on the books—which existed as a matter of fact.

The engineering method in its simplest form implies that the engineer can by his personal inspection determine the physical deterioration, the liability to obsolescence and inadequacy, and any other of the factors in the depreciation of the property under consideration. If he can do this he can justify his method. In so far as he relies on or colors his judgment with ideas of average length of life, he has departed from strict engineering methods. It will be seen, therefore, that while the accounting method depends but little on mental equipment of the appraiser, the engineering method relies on it almost entirely. If we not unreasonably assume any advantages for the latter method, it follows that they exist in fact only when applied by the right sort of man.

As a matter of fact and of practice the best results in appraisal are not secured by purely engineering methods as defined above, and one reason why the engineer is likely to make a better appraiser is that he is in a much better position to adopt any profitable accounting methods than the accountant is to adopt engineering methods. For example, there are at least three different values that usually appear in a valuation report: First, cost or investment values; second, replacement values; and third, the depreciated values derived from the first two. It is safe to say that if the first two values can be found by accounting methods they will be more accurate than if figured by the engineer. For the cost value there is nothing that can exceed the invoice cost for accuracy and authority, plus, of course, transportation and erection cost. If the invoice is not available, it can often be valued by office records of the cost of similar commodities at a time as near as possible to the date of purchase of the original item. This figure may need to be corrected for any known change in prices between the two dates. If neither of these methods is possible, the question reverts to one of an engineering estimate of the cost of building and selling such a machine, which is very unsatisfactory. The cost to produce depends on the quantity produced and various other factors which are not likely to be known. Furthermore the selling price of an article is controlled by other factors than shop cost. It will be seen, therefore, that here is a case that should be handled by engineering methods only as a last resort.

The replacement or basis for insurable value is the next item. This is also valuable information for those companies whose system of accounting includes a reserve for depreciation, or sinking fund for replacements. This value represents what a similar article would cost new at the time of appraisal, but it usually happens that in ten years or more such articles have been improved upon. The same company may make them, but with such improvements as make them more expensive. The question now arises, should the replacement value be the estimated cost of a similar article as if it were a commercial product, or the actual cost of the nearest similar article now made to do the same work? In practice this is largely an academic question, or at least one to be settled as a matter of expediency, but it may be said that whatever light is shed on the problem will be furnished by the engineer. He is the one who must pass on the suitability of available equipment, or furnish an estimate of the present theoretical replacement cost of a duplicate article.

It is only when such commodities are in the nature of standard equipment that the foregoing methods are applicable. That is, the value of a lathe, either cost or replacement, may be so determined if it is of standard construction, but if it be a special-purpose machine built to order, or, as is commonly found in machine shops, special jigs and tools, these are to be handled only by the engineer, and he will find few problems of valuation that are more difficult to handle.

Depreciation from these values to determine the present remaining value, or the theoretical replacement value allowing for wear, etc., is the most difficult part of appraisal and is distinctly an engineer's problem, whatever other sciences, trades or professions he may draw on for assistance.

Depreciation is either a process that can be detected by the senses, or it is something that experience has shown exists, even if we can detect no sign of its progress. The odor of a hot bearing, the sound of worn gearing or their inspection by sight, touch, or measurement, are practical demonstrations of depreciation. Any or all of these may not establish its exact extent or percentage, but they at least are palpable evidence of it. There is also the depreciation due to chemical or molecular change such as crystallization of an axle, or the burning out of an incandescent-light bulb. Any examination not involving the destruction of the article itself would show no indication of impending failure, even though it were to fail within the next hour. The depreciation of a lead pencil can be established definitely. It is a definite length when new. It is discarded at another reasonable definite length. It can be measured at any time, and the percentage of remaining available service established, which it will be noted is something altogether different from predicting how much longer the owner will use it. The one is a statement of present facts, the other is an attempt to use this information in an attempt to read the future, something that is often necessary, but always dangerous. On the other hand, it is in general a waste of time to attempt by inspection to establish definitely the present condition of an electric motor. It may run without mishap for years, or it may burn out within the next five minutes. No inspection that it is practical to make for valuation purposes could predict either case, nor could the most careful laboratory tests determine when it would next be subjected to an overload beyond its capacity.

The causes of depreciation such as wear, obsolescence, inadequacy, etc., have been enumerated too often to require it here, but in addition to these there are various intangible factors that often overbalance all others. For example, if a shop superintendent believes that a certain machine is obsolete, so far as his shop is concerned, it *is* obsolete, notwithstanding the fact that another man might think otherwise; and the fact that it is obsolete is due to the decision of the man who ordered it scrapped, rather than to anything inherent in the machine. With tangible causes of depreciation the difficulty is not in recognizing them but in measuring their effect in dollars. Wear is easily detected, or measured if need be, but how will you translate thousandths of an inch of wear into dollars of depreciation? With standard types of familiar machines, such as engines, pumps, lathes, motors, etc., the degree of obsolescence or inadequacy may be easy to determine, but in the case of special machinery such as automatic bottle-blowing machinery, looms for wire fencing, or automatic machinery for watch parts, the results of inspection may not be very fruitful. Mechanical engineering is divided and subdivided so often, with a different kind of fruit at the end of each branch, that no one man can be expected to be an authority on all of them. With these problems it is a question of knowing where to find the right information, and being able to get it.

There is one fundamental difference between engineering and accounting appraisals that has been previously hinted at. An engineer standing in front of a machine says, in effect, "This machine, now, today, has 75 per cent of its original value left. I do not care how old it is, or whether the repairs will be kept up in the future. It is in good running condition now, the superintendent is satisfied that even if it is not the very best design for his purpose, it is well up in the list, and without attempting to predict anything that may happen to it in the future, I make my report all in the present tense." If called on to justify his figures, he can point to the satisfactory operation of the machine both as to quality and quantity, and the superintendent can qualify as an expert on that type of machinery. The accountant's report is: "This machine is 10 years old, general practice and various authorities give 20 as the average life of machinery. The remaining life and value is therefore 50 per cent of the original cost. I am not in a position to consider whether or not unusual and extraordinary repairs have been made, or what the plans of the operating force may be with regard to it. I work on the law of averages. If I am not strictly accurate in this particular instance, the accuracy of the total results is not necessarily impaired." The original source of his justification will be found somewhere in a book.

If a considerable volume of statistics were available on the actual active life of different kinds of machinery, extending over a period of at least 30 years, it would be possible to secure a true average life, either of any one kind of machinery, or of machinery as a whole. But no such records exist. Even this is not enough. What is desired in appraisal is a valuation of the particular property under consideration, with consideration for its individual characteristics, and not a cross-section of the average experience of machinery users. The more specialized the nature or conduct of

following report made by an engineer on the valuation of the machinery in such a plant is offered as an example:

July 14, 1920.

It will be noted that numerous machinery items have been depreciated comparatively little, considering their nominal age. The reason for this is as follows:

In Departments A and B the machinery is all of a highly special nature, a major percentage having been either made or materially improved in your own shops and no equally productive machines can be purchased elsewhere. Concrete evidence of these repairs and improvements will be found in the 452, patterns—made for improvements alone—now segregated in Building No. 14.

In general, the manufacturer is able to purchase his machines in the open market, and for this reason does not find it necessary or even advisable to make extensive repairs, but in this instance this does not hold. In case of fire or other total loss, a large part of this special machinery would necessarily be built in their own shops, and the remaining part would require extensive changes to give them a productive value equal to the present equipment.

As a result of these conditions, it has been the persistent policy of the company to give unusual care and attention to repairs. The plant is closed for one week each year, and advantage is taken of this to make repairs that would otherwise be neglected.

In Department C the splitting and shaving machines are simple in construction and have easily renewable parts, consequently the maintenance expense is comparatively small. On the other hand, the cost for repairs in the Weaving Department is a heavy item. Notwithstanding this, however, these machines have been maintained in good condition. For example, —three looms which originally cost less than \$700 each were repaired and improved in 1908 at a cost of \$1830 each (See Journal No. 2, p. 54).

The fact that no better machines are known to exist indicates that there is no depreciation for obsolescence. The fact that repairs are of an unusually extensive nature, indicates that depreciation for wear is correspondingly unusual. The result of these two factors is that the depreciation of these machines is unusually small.

This report indicates the necessity for a thorough investigation of both mechanical and industrial conditions in the plant under consideration, and for this sort of work there is no one better fitted than the engineer. The broader his industrial experience, the better he is fitted for the task. Engineering *methods* are not enough, engineering personnel in the field staff is vitally necessary. Satisfactory results from any method or process presuppose the use of the indicated materials.

Columbus, Ohio. L. L. Thwing.

Concerning Honorary Membership

To the Editor:

Members of about twenty years' standing who remember the old brownstone club house in which the mechanicians of twenty years ago used to gather, will find the new order and new ideals as set forth by our engineering prophets Mr. Cooke, Mr. Hoover, et al., most inspiring.

But as the boys say, the young "grad." this June will be asking, "How do you get that way?"

May it not be summed up in words of one syllable for them once for all by one who has been a "prof.:"—To be a good engineer, "an exceptional man," be something else, or something else also.

Be a portrait painter like Robert Fulton, a polar bear hunter and north pole hunter like dear old Melville, engineer of the universe like dear old Uncle John Brashear, or an engineer of humanity and capitalist like dear old Doctor Andrew Carnegie, and become an Honorary Member like these.

The universe being a mechanical phenomenon, it don't make any difference what you do well—you are a successful mechanical engineer, even if you don't know it till you are elected, like Mr. Charles M. Schwab, Honorary Member.

This is as it should be, and agrees with the conclusions of laborious investigations of the Society for the Promotion of Engineering Education, which I understand were:

1 That engineering education didn't need any promotion, it was just a natural phenomenon going on of itself;

2 That the less technical details a man learned or the more he forgot, the sooner he came into harmony with this natural phenomenon and became a good engineer and material for honorary membership.

When this inspiring process is carried to its logical conclusion as outlined by Mr. H. G. Wells and other engineers, we shall all be Honorary Members and the Society, having outlived its usefulway."

Arcadia, Los Angeles, Cal. David H. Ray, Sc.D., Mem. Am.Soc.M.E.

The Question of Entropy

To the Editor:

In the June issue of Mechanical Engineering I find an article by Prof. G. A. Goodenough relative to a criticism made of American steam tables in a review of Professor Callender's tables contained in London *Engineering*. The particular statement objected to is— "the elaborate tables compiled in America.....fail to satisfy the test...that the work done in a given cycle should be the same whether measured on the temperature-entropy chart or on the indicator diagram."

In respect to this matter, I beg the privilege of submitting that the criticism made is apparently, but only apparently, sound. I have spent the last six years in a complete restudy of heat and allied subjects, developing new vapor equations, etc., which, while attacking the problem from an entirely new viewpoint, show that the truth lies almost exactly between the values given in Goodenough's steam tables and those given in the Marks and Davis tables, while the work of Keyes and Bromlee on ammonia at the Massachusetts Institute of Technology is, for accuracy, probably the most remarkable piece of experimental work ever accomplished anywhere in the world.

That there is an inconsistency between the temperature-entropy and pressure-volume diagrams is due to an entirely different matter that happens to be to the credit and not to the discredit of these tables for the reason that entropy is *a complete error*. To substantiate this statement I submit (*a*) a mathematical proof, (*b*) a physical proof, and (*c*) its probable original derivation, as follows:

(*a*) Assume that entropy is true to begin with. By definition—

$$dN = \frac{dH}{E}$$

where N is the entropy, H the heat energy, and E the absolute temperature. Since entropy is a function of H and E, we may write—

$$N = f(H,E)$$

Differentiating this equation gives—

$$dN = \left(\frac{dN}{dH}\right)_E dH + \left(\frac{dN}{dE}\right)_H dE$$

the parts in the parentheses being the usual partial differentials. We can therefore equate the two values of dN, getting—

$$\frac{dH}{E} = \left(\frac{dN}{dH}\right)_H dH + \left(\frac{dN}{dE}\right)_H dE$$

This equation is satisfied only when—

$$\left(\frac{dN}{dE}\right)_H = 0$$

and therefore E = a constant. That is, entropy is an error except when the temperature is constant.

(*b*) Assume again that entropy is true. We have then that

$$H = \int EdN$$

Let us now have reference to the temperature-entropy diagram shown in Fig. 1. Suppose a substance is originally under the conditions indicated by the point 1 and that its thermal conditions are changed until they are as indicated by the point 2. According to the equation $DH = EdN$ the heat added will equal the area under the path by which the thermal conditions are changed from the conditions 1 to the conditions 2. If, for example, the path of change is $1A2$, the heat added, according to this equation, will be the area under the curve $1A2$. If it is changed by the path $1B2$, the heat added will equal the area under the curve $1B2$; and similarly for the curve $1C2$, or any other conceivable curve. According to the equation $dH = EdN$ the heat content of a substance for any given conditions (E,N) is infinitely many-valued. As a matter of fact, the heat content of a substance depends only upon its final conditions and not at all upon the path by which these final conditions were arrived at. A pound of dry saturated steam

has a certain heat content when at, say, a pressure of 100 lb., irrespective of how this steam was produced, whether by heating up a liquid, or cooling down from the superheated state, or any other way. The conclusion is therefore enforced that the equation $dH = EdN$ is not true.

(c) The calculus teaches that the area A under a given curve $y = f(x)$ is—

$$dA = ydx$$

We thus have two simultaneous equations, namely,

$$y = f(x) \text{ and } y = dA/dx$$

Letting

$$y = E, \ A = H, \text{ and } x = N$$

then

$$E = dH/dN$$

or

$$dN = \frac{dH}{E} \quad [1]$$

and

$$E = f(N) \quad [2]$$

Equation [1] is meaningless without Equation [2], for what can be the area under a curve when there is no curve?

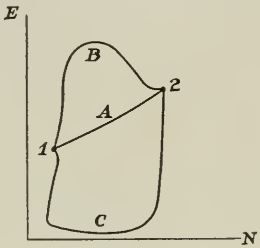

Fig. 1

I think that heat engineering will be greatly benefited by getting away from this age-old error. I know that it has proved so in my case.

U. S. Patent Office Relief

To the Editor:

I note your article in the July number of Mechanical Engineering on U. S. Patent Office Relief, and wish to say that too much publicity cannot be given to Patent Office conditions.

In my opinion the Patent Office stands at the very foundation of industrial welfare and progress. Great industries are founded on patent rights; they either could not have been founded at all or would have been greatly delayed if the inducement of a limited period of enjoyment of the fruits of the invention had not been given. Mechanics and students of the sciences are constantly striving to accomplish great inventions, and in many cases their sole incentive is a patent whereby their fortunes may be assured. I doubt if there is a single engineer of any standing who has neither secured nor applied for a patent.

Consequently the administration of the Patent Office is of great moment to both engineers and manufacturers, whose success often depends on valid patent rights. It is desirable that applications receive prompt action, but above all things such action should be the result of a careful search by competent examiners.

At the present time neither of these requisites can be fulfilled by the Patent Office, because there is a shortage of examiners and this shortage exists principally among the older, more skillful examiners, who are daily being lured away from the Office by higher salaries. At the present time I have applications pending in mechanical engineering classes that were filed nine months ago, and on which I have received no act on. About one-third of the applications filed are not acted on for six months or more.

Surely this situation would be remedied if brought forcibly to the attention of the representatives in Congress.

Engineers, inventors, manufacturers: write your representative to vote for the Lampert Bill.

St. Louis. Mo. H. A. Baimes.

The Banki Hydraulic Turbine

To the Editor:

The May issue of Mechanical Engineering on page 345 gives particulars regarding a "new" hydraulic turbine, the invention of Professor Banki of Budapest. This development has been given considerable publicity, but engineers and manufacturers of hydraulic turbines have been practically unanimous in agreeing that the design does not incorporate those features of efficiency, reliability and reduction of first cost which are the fundamental requirements in modern turbines.

The turbine in question is very close in its major characteristics to the Girard type of turbine in use twenty or thirty years ago, but since discarded. This type of turbine has not been built in any appreciable quantity for the last fifteen years and is not in any way a factor in modern development because it possesses numerous operating disadvantages in connection with pitting of the blades and nozzles, low efficiency, and uneconomical arrangement. These comments apply to the Girard type of turbine arranged with a single application of the jet. All of the disadvantages would be greatly increased in the attempt to pass the jet through the wheel a second time. As a matter of fact, it is not conceivable that a jet, having passed a set of buckets, should remain in a state capable of developing additional power at desirable efficiency.

The inventor of the turbine under consideration fixes the diameter of the wheel at $D = 72.86\sqrt{(H)}/n$. In terms of peripheral coefficient this formula means that the rim runs at a speed equal to $0.48 \sqrt{(2gH)}$. This peripheral coefficient of 0.48 is the same as is used on standard impulse wheels, so from that standpoint there is practically no advantage in the type proposed. While it is possible to use a smaller diameter and consequently higher r.p.m. and maintain this same coefficient, the most extreme proposition that could be secured is far below that easily obtained with the Francis type of runner, which has a peripheral coefficient of 0.6 to 0.7 for the heads to which the proposed wheel is apparently adapted. Furthermore the Francis turbine can be reduced in diameter to a much greater extent than can the proposed Banki wheel in the effort to secure higher speeds. There might be an advantage in the Banki wheel in connection with the width of opening between buckets, this being an advantage as regards clogging on smaller-sized wheels, but the other mechanical disadvantages of the Banki arrangement, particularly in connection with arrangement of nozzle, far outweigh this single point.

In addition to amplifying the features which caused the Girard turbine to be a commercial failure, this type of wheel possesses the inherent disadvantage of an impulse wheel, that is, it must be set above tail-water level so that with the medium-head field, which alone is open to this type of development, there is a prohibitive percentage of loss due to its application.

From a theoretical hydraulic standpoint there is considerable justification for some of the contentions made. From a standpoint of practical hydraulic engineering there is no advantage. Mechanically the wheel can hardly be arranged to permit of the use of a needle type of nozzle, which alone has stood the test of time in the development of the impulse type of turbine.

Engineering Schools

To the Editor:

On page 420 of the June issue of Mechanical Engineering, Dean Bishop is quoted as saying "There is no first-class engineering school to be found in America." Taken by itself as printed and with no explanation of the word "first-class" it is a surprisingly frank statement, but I fear it may tend to compromise our engineering education in the eyes of some who may think it is really true. In the words of Dr. Adams, who supported the charge, it "neglects most of the variables." Probably the speaker desired simply to "start something" in the same way as did Edison with his questions for the college men.

Your report of discussion includes the following comments by Dr. Comfort A. Adams:

In support of the last and rather startling statements made by Dean Bishop the chairman said that he would guarantee to take the graduates in electrical engineering from any institution in this country and prove in a

five-minute oral examination of each one, in 98 or 99 per cent of the cases, that the men do not understand in any thorough fashion the fundamentals of the subject; that in most cases they do not even know the meaning of the words they use; that they are carried through analyses of comparatively complicated problems, but in a machine-like superficial way, neglecting most of the variables, so that they get into the habit of a kind of loose thinking which so affects all their work that they cannot be counted on for any sound results.

Does not Dr. Adams miss the point? The highest aim of the teacher is to direct the student to think for himself, rather than to carry him through "comparatively complicated problems in a machine-like, superficial way." The good teacher has that higher aim constantly in mind. Measure up your graduate by that as well as by the test mentioned by Dr. Adams and see if 98 or 99 per cent of the graduates will fall down. If over 90 per cent do fall, then you may more safely conclude there is no first-class engineering school in the country; but don't place the charge solely upon the depth of abstract knowledge which a man ten years out of college in responsible work would also fall down on if put to the same test.

True, we need more than ever a larger number of first-class engineering schools, but more than that we need a greater stress laid on the fundamentals in all the engineering schools of the country. Measure the standard on the basis of ability to think clearly rather than solely on the ground of a multitude of accumulated facts. We need to cultivate the engineering type of mind, and that calls for elements of character as well as elements of knowledge.

State College, Pa. ARTHUR J. WOOD.

Progress Report on Symbols in Heat Engineering

Preliminary Report of The American Society of Mechanical Engineers' Standing Committee on Technical Nomenclature

SINCE July 1917 The American Society of Mechanical Engineers has had a committee coöperating with a similar committee of the Society for the Promotion of Engineering Education for the purpose of systematizing and standardizing technical nomenclature. Recently this committee was made a standing committee of the Society and for the past year or more it has devoted its attention to the subject of heat engineering.

The report which appears below is of a preliminary nature and is printed here to elicit general discussion by those interested in this phase of the subject.

The Chairman of the Committee is Mr. W. D. Ennis, and he may be addressed in care of The American Society of Mechanical Engineers, 29 West 39th Street, New York City.

THE PRELIMINARY REPORT

1 The concepts or quantities relating to a liquid, its saturated or its superheated vapor for which symbols are most commonly used are:

Heat content
Temperature
Pressure
Volume
Entropy.

In addition, the following quantities are commonly symbolized:

Specific heat of superheated vapor at constant pressure
Mechanical equivalent of heat (778)
Dryness (saturated vapor)
Latent heat of vaporization (rarely that of fusion)
Entropy of vaporization
Internal and external portions of the latent heat of vaporization
Ratio of specific heats of gases
Specific heats at constant pressure and at constant volume (gases).

Less commonly used symbols are those for—

Reciprocal of the mechanical equivalent of heat density
Absolute temperature.

2 As the result of a few preliminary letters and some oral discussion, the following principles seem to command rather general (though not universal) assent:

(*a*) Greek letters should be avoided.
(*b*) Dimensional symbolism should not be attempted.

3 The standardization most needed is that which relates to symbols for properties of liquids and their vapors—particularly water. There are three physical conditions to be distinguished: liquid, saturated vapor (wet or dry), and superheated vapor. It is natural to use small and capital letters for two of these conditions: as h, H; t, T; v, V; n, N; for liquid and saturated vapor. The third condition must then be designated (unless by a different letter) by either a prime or a subscript.

Primes are not likely to be confused with exponents, because the latter are rarely used in heat engineering. The chief objection to them is one of typography—they are apt to break off or slip out.

Subscripts are objectionable because they are also needed to refer to stated points. Thus if N_1 denotes entropy of superheated steam, we might have to write $(N_1)_a$ and $(N_1)_b$. Both are awkward forms and do not sound when enunciated verbally.

4 Absolute temperature could be designated by $t + 460$, $T + 460$, etc., and no special symbol is imperatively necessary, although many writers use t for fahrenheit and T for absolute.

5 Present usage seems to indicate maximum popularity for the following:

Cp, J, p, t, h, L or r, H, v
(with primes or subscripts)

For other quantities there is no uniformity of symbolism.

By using the following, there would be no departure from generally accepted usage:

Heat content	h, H, H'	
Temperature	$(t = T)$ T'	
Pressure	p	
Volume	v, V, V'	
Entropy	n, N, N'	(It is true that n is often used as the polytropic exponent)
Mechanical equivalent of heat	J	
Its reciprocal	A	
Dryness	x or q	(preferably the latter)
Latent heat of vaporization	$L = H - h$	
Entropy of vaporization	$N - n$	(no single symbol.) See Note.
Internal latent heat	r	(implies the use of L for total latent heat)
Ratio of specific heats	y	(suggests a former Greek symbol)
Specific heat at constant pressure	C_p	
Specific heat at constant volume	C_v	

NOTE:—There is perhaps a real need for a single symbol. The entropy of a wet vapor would be—

$$n + q\,(N - n) = qN + n\,(1 - q)$$

If for $(N - n)$ we had a single symbol, l (though this might be useful for latent heat of fusion) there would result the simpler form—

$$n + ql$$

Tests carried out on paint-spraying machines have shown, according to the *Architect*, that spraying requires approximately 10 per cent more paint than brushing when the surface being treated is an iron roof, while brushing requires approximately 200 per cent more labor than spraying. On exterior brick walls spraying requires 7 per cent more paint than brushing, while brushing requires 109 per cent more labor than spraying. On interior ceilings and walls of plaster spraying requires 40 per cent more paint than brushing but gives a better hiding in one coat. On similar work brushing requires 160 per cent more labor than spraying, and gives a poorer hiding in one coat. Although it has not been possible as yet to arrive at a definite conclusion confirming the relative durability of spraying as compared with hand painting, it is claimed that the investigations so far made tend to support the belief that the spraying work will last longer.—*The Engineer* (London), July 25, 1921.

What the Virginia Capes Aircraft Bombing Tests Show

THE conflict between the air bombing squadron and the ex-German battleship *Ostfriesland* off the Virginia Capes was an epoch-making incident in the ever-present conflict between the old and well-established and the new and untried. The new device proved successful and indicated a future.

Elmer A. Sperry

When the United States entered the world war in 1917 it did not possess a single military flying machine, and of the two score training planes then owned by the Army and Navy there were barely a baker's dozen capable of an hour's flight. Not quite four years have elapsed between the foundation of American military aeronautics and the sending out of the unprotected David of the air with a few bombs to do battle with the Goliath of the sea protected with armament representing forty years of sustained development costing billions of dollars. The battleship went to the bottom of the ocean in less than twenty-five minutes. Still the aircraft engineers responsible for this remarkable performance thoroughly realize the crudeness of the airplane, especially as regards the sighting, aiming and bomb-dropping devices.

The battleship can be made larger and faster, but this will not make it less vulnerable to aerial attack. The airplane, however, is only at the threshold of its development. The question seems to be one of time when the battleship will be driven from the sea.

American engineers have particular reasons to glory in the success of our flyers. The planes used were chiefly of American design, driven by a typical American motor. The bold conception of the test was on a par with the big things done every day by our engineers, and the daring of the men who flew for over a hundred miles out to sea in planes which had no facilities for landing on the water is something of which the nation may well feel proud.

Great honor must be given to the persistent and marvelous organization of the Air Service, which carried this difficult task to such successful completion. This is due in large measure to the enthusiasm and leadership of General Mitchell and his extremely able corps of assistants. Colonel Bane, chief of the Engineering Division of the Air Service, is another who should receive no small amount of praise and congratulations.

From my experience in connection with the production of the first depth bomb for the Navy, I am convinced that it is the only device capable of reaching the vulnerable parts of a battleship. The enormous sledge-hammer blow that is delivered to the ship's structure by a depth bomb at a distance is something prodigious. The compressibility of water being only 1/150 at the pressure of one ton per square inch, it acts to all intents and purposes as a perfect solid in transmitting the enormous concussion. Mass action is the secret of the success of the depth bomb, as is shown in the following formula:

$$P = \frac{0.68\,WK}{D^{1.39}}$$

where P is the effective pressure in tons per square inch against the target from the depth bomb; D the distance from the center of the charge to the face of the target, in feet; K the coefficient, which for the TNT equals 3.17; and W the weight of the charge in pounds.

In early bombing days, from the heights to which anti-aircraft guns drove the aircraft it was lucky if the bomb was able to hit the township containing the target. The precision obtained since that time in the various elements of the bombing equipment is due in no small measure to the astute, practical mathematician, the man who is 100 per cent mathematician and also 100 per cent engineer, in being able to point out a practical and physical, as well as simple, solution of otherwise very perplexing and abstruse formulas. This, together with the new method of stabilizing, finding and being able to hold the exact vertical reference line, and precision flight due to great care on the part of the pilot, are all important elements, but in the last analysis the level head and horse sense of the "man behind the gun" constitute no small part of the answer.

So aircraft, which is the natural American heritage, is coming not only into its own, but assuming nothing short of sovereign leadership in direct offensive action, and it has remained for America again to lead the way.

There are many defensive actions in which aeronautics will from now on take prominent leadership, and all are based on the most highly organized engineering analysis and skill. I therefore recommend that our Aeronautic Division make a close study of these intensely interesting activities so as to be in readiness to extend first aid in this all-important development.

Elmer A. Sperry.

The Value of the Waste Report

THE report o fthe Committee of The Federated American Engineering Societies on the Elimination of Waste in Industry, an abstract of which we publish elsewhere in this issue, has recently been released.

Some criticism of it has appeared, based evidently upon too brief and incomplete extracts from it. In the main, however, comment upon the report has been intelligent and appreciative, and we believe will be more so as the complete report is studied and understood.

The carefully prepared "Questionnaire" used by the field workers for the committee has been declared by some of the shrewdest and most progressive manufacturers to be in itself a valuable thing that ought to be meditated upon by every one in any way responsible for the conduct of industrial operations.

The report shows that the opportunity of management for improving industrial affairs is much larger than that of "labor," and upon this point the report sustains the opinion of practically all trained observers who have studied the matter, including many industrial managers and proprietors of manufacturing establishments themselves.

The real value of the Waste Report will be determined by its success as a stimulant to future waste-eliminating activity.

In the industry of this country there are a great many variables, the evaluation of which, to permit comparison between plants or

divisions in the same industry or between the various industries, cannot but lead to greater or less differences of opinion about the findings of any group of men. The report, however, definitely points out wastes and recommends steps for their elimination. This last is the work of years, calling for the concentrated, coöperative effort of every individual and organization interested in industrial administration and development. This effort should not be dissipated in combating statements in the report that happen not to please. Wastes must be eliminated, not argued away, if the industries of America are to stand the test of the future. As the product of capable, conscientious men, realizing the tremendous importance of the subject, this report deserves more than criticism of details, especially since its great mission is that of a call to service in waste elimination.

Admittedly preliminary in character, the Waste Report sheds enough light on the situation to show the way of future waste-elimination procedure.

The American Society of Mechanical Engineers is taking the lead, and the 1921 Annual Meeting will be devoted to the subject of Elimination of Waste in Industry. Although the program has been prepared without definite relation to the Waste Report, the various Professional Divisions will present definite technical contributions to waste elimination in their various fields. The following subjects indicate the character of the meeting: Power-Plant Heat Balance as a Factor in Economic Operations; Avoidable Losses in Locomotives; Waste in Small Machine Shops; Hidden Wastes in Textile Mills; Importance of Research in Waste Elimination; and Development in Boiler and Furnace Design as a Factor in Reducing Fuel Waste. The presentation and discussion of these papers on that occasion will constitute a strong attack against waste.

This meeting will be but a step forward, however, and great strides are necessary. The report should be studied carefully by every industrial and business leader so that the results of this intensive study may be put to work at once in every industrial establishment where there is the desire to advance the economy and industrial technique of the country. Furthermore, general familiarity with the Waste Report should stimulate thought and action toward the development of an aggressive program for waste elimination.

The DeLamater Ericsson Tablet Committee

March 9, 1922, will be the sixtieth anniversary of the battle of the *Monitor* and *Merrimac* at Hampton Roads, Va., which demonstrated the merits of the turreted battleship. That has been the date selected by the DeLamater Ericsson Tablet Committee to memorialize the services of Mr. Cornelius H. DeLamater and Capt. John Ericsson, who for 50 years, 1839–1889, were pioneers in developing the naval, marine and industrial interests of this country, and who at the time of the civil war, without thought of personal reward, turned their mental and financial resources to account and applied their knowledge and experience to accomplish what the Government had failed to do.

The Government has appropriated $35,000, and private individuals have subscribed a larger sum for a memorial to Captain Ericsson in Washington adjacent to the Lincoln Memorial, and $5000 is being raised by private subscription among engineering and marine interests to erect bronze tablets on four sites of buildings in New York City with which the lives and work of the two men were identified.

These are (1) The Phoenix Foundry, 260 West Street, between Laight and Vestry Streets, where the first iron boats in this country were built and the screw propeller was first introduced on river and ocean steamers. Some of the equipment of the *Princeton*, the first battleship with machinery and boilers below the water line safe from cannon shot, was constructed there, revolutionizing the navies of the world. The 3-in. pipe for the Croton Aqueduct and hot-air engines to pump the Croton water to the upper floors of houses were conceived and built there, as well as much other notable work. (2) The DeLamater Iron Works, foot of West 13th Street, where many industries now internationally established obtained their first development. There the first self-propelled torpedo, the first torpedo boat, the first submarine boat, and the engines for the original *Monitor*, were built, and the *Dictator* was built complete. (3) The Continental Iron Works, Greenpoint, Brooklyn, L. I., where the hull of the original *Monitor* was built and the *Puritan* and other monitors were built complete; and (4) No. 36 Beach Street, where Captain Ericsson lived and worked and died. By the *Monitor*, the navies of the world were revolutionized a second time.

The movement to erect these tablets started at the DeLamater Ericsson Commemoration meeting held December 3, 1919, in the auditorium of the Engineering Societies Building, 29 West 39th Street, in which the following twelve engineering and civic organizations participated: The American Scandinavian Alliance of Greater New York; American Scandinavian Foundation; American Scenic and Historic Preservation Society; The American Society of Mechanical Engineers; American Society of Naval Architects and Marine Engineers; American Society of Refrigerating Engineers; American Society of Swedish Engineers; Associated Veterans of the DeLamater Iron Works; Engineers' Club of New York; General Society of Mechanics and Tradesmen; John Ericsson Memorial Committee; New York Historical Society; and The Union League Club.

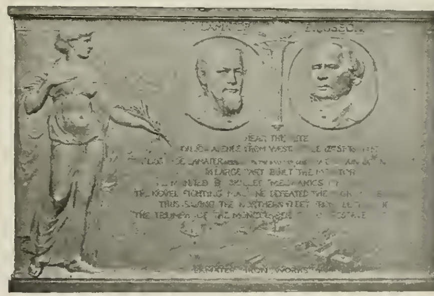

Table to Mark Site of DeLamater Iron Works

Since then the following additional societies have joined the movement; Amaranthus Lodge, I.O.O.F.; Bredablick Lodge, F. & A.M.; Captain John Ericsson Memorial Society of Swedish Engineers; Engineers' Club of Trenton, N. J.; Past District Grand Masters Association; and the United Swedish Societies of New York. A number of prominent marine interests and private individuals have subscribed to the Tablet Fund.

Mr. Isidore Konti is the sculptor, the Municipal Art Commission has accepted the design and the American Scenic and Historic Preservation Society will serve as guardian of the tablets.

The Committee proposes to unveil the tablets in the afternoon of March 9 and in the evening to hold a public dinner meeting at one of the large hotels, at which representatives of the Swedish and United States federal, state and municipal governments, as well as of prominent marine and industrial interests, will be present and speak. The children attending the various public schools located near the localities of the tablet sites will participate in the ceremonies.

The Committee would like to hear from other technical societies, civic organizations, marine and industrial interests and individuals who desire to show their patriotism and appreciation of the services to the country of Mr. DeLamater and Captain Ericsson by participating in this movement. Any money left after the tablets are erected will be devoted to the establishment of a depository for relics and memorabilia of Captain Ericsson, of which there are already considerable in hand. Correspondence should be addressed to The DeLamater Ericsson Tablet Committee, Engineering Societies Building, 29 West 39th St., New York, N. Y. This Committee consists of H. F. J. Porter, *Chairman*, Oakley R. De Lamater, Frederick A. Halsey, Axel S. Hedman, Ernst Ohnell, Henry R. Towne, and Charles Vezin.

Death of Dr. George F. Blessing

George F. Blessing

Dr. George Frederick Blessing, professor of engineering at Swarthmore College, passed away at his summer home at Bay View, Mich., June 24, after a brief illness. He was born in Carrollton, Ky., in 1875, and was a graduate of Kentucky University and also of Hanover College, Ind., from which he received the degree of Ph.D. in 1908. After graduation, Professor Blessing spent several years in practical work, becoming professor of mechanical engineering at the University of Nevada in 1899, where he stayed till 1905, spending his summers in practical work with various concerns on the Pacific Coast. In 1905 he became connected with the General Electric Company at their Lynn works as a designer in the steam-turbine department, and in 1906 he became assistant professor of machine design at Cornell University. In 1908 he accepted the position at Swarthmore which he held at his death.

Professor Blessing was essentially a great teacher. Gifted with a brilliant mind, he also possessed the interest in his fellow-beings so essential to the successful teacher. At the time of his death he was employing a leave of absence from university work in making an investigation of industrial conditions for Mr. John D. Rockefeller, Jr., in the mines and mills of the Colorado Fuel and Iron Company in Colorado, and in endeavoring to develop new ideas in this work. The result of this work and similar previous experiences was to have been published in book form and it is hoped that the large amount of material gathered can be edited and published in the near future, as such a volume would undoubtely prove of great value to students of industrial conditions. Overexertion incident to this work brought on a physical breakdown from which he failed to rally, and his illness was of short duration.

Professor Blessing was the author of books on machine drawing and descriptive geometry and of various contributions to the technical press. He was a member of The American Society of Mechanical Engineers, the Society for the Promotion of Engineering Education, the Efficiency Society, the Engineers' Club of Philadelphia, and the honorary scientific societies of Sigma Xi and Tau Beta Pi.

In his death the Society and the teaching profession lose an able engineer, a fine teacher, and a man of sterling qualities and of lovable character. His untimely end will be deeply regretted by a host of friends and former students throughout the entire country. Few men possess the attractive personal qualities that endeared him to a very large circle of acquaintances.

Conference to Stabilize Road Building

Herbert Hoover, Secretary of Commerce, called a conference of engineers and state highway officials on July 18 in Washington. The purpose of the conference was to obtain engineering suggestions and criticisms on the advisability of awarding highway contracts in the fall for the next season's work. This would stimulate the buying of materials and equipment early enough to give a stable period for the manufacture and shipment of such materials and would also enable the contractor to plan in the winter for his work in the coming year and to devote all of his time and efforts to the construction of roads in the favorable part of the summer. The following men attended the conference: Col. W. D. Uhler, chief engineer, State Highway Department, Pennsylvania, representing Civil Engineers; Mr. Coleman, chief engineer, Highway Department, State of Virginia, representing Association of State Highway Officials; Mr. Upham, chief engineer, State Highway Department, North Carolina, representing, the State Highway Officials; Gen. R. C. Marshall, Jr., general manager, Association of General Contractors; Prof. W. K. Hatt, representing National Research Council; Thomas MacDonald, chief, Bureau of Public Roads, Department of Agriculture; L. W. Wallace, executive secretary, American Engineering Council; and R. M. Gates, representing The American Society of Mechanical Engineers.

The conference prepared and presented a report in which were pointed out the engineering advantages of fall awarding of highway contracts, namely, a much longer construction season and a consequent better service in the handling of highway construction materials; less fluctuation in construction and a greater possibility of completion of highway programs. This system would permit interseasonal work with resulting increase in the continuous employment of labor, more uniform production in basic industries, and more efficient road-building organizations.

The conference did not substantiate the assumption that the cost of road-making materials is generally high in the fall. From the report of the conference Secretary Hoover prepared a memorandum for the governor of each of the states, which he forwarded to them with the earnest request that the matter be given careful consideration in view of the need for economical construction and the stabilization of employment and manufacture of material and equipment.

Highway Research on a National Basis

The Advisory Board on Highway Research which was established by the Division of Engineering of the National Research Council, with the coöperation of Engineering Foundation at a conference held in New York last November, has recently engaged William Kendrick Hatt, professor of civil engineering and director of the materials testing laboratory, Purdue University, to direct its work in national highway research.

The purposes of the Advisory Board are:

a To assist existing organizations in outlining a comprehensive national program of highway research and coördinating their activities thereunder

b To organize committees for specific problems

c To act in a general advisory capacity

d To serve as a clearing house for highway research information.

The Advisory Board is composed of fifteen organizations of national importance interested in the design, construction, economics, maintenance and financing of highways, in materials and equipment therefor, and in vehicles used on highways; governmental departments and bureaus of similar interests, and higher educational institutions. In addition to the member organizations, which include The American Society of Mechanical Engineers, thirteen state highway departments and more than forty universities have definitely signified their interest in the work of the Advisory Board and their willingness to coöperate.

Anson Marston, dean of engineering, Iowa State College, and a member of the Iowa State Highway Commission, is chairman of the Board, and Alfred D. Flinn, secretary of Engineering Foundation and vice-chairman of the Division of Engineering of the National Research Council, is vice-chairman.

Three technical committees have been at work for a number of months. These are the committees on Economic Theory of Highway Improvement; on Character and Use of Road Materials; and on Structural Design of Roads. Committees on Vehicle Design as Related to a Road; on Economics and Cost of Transport; on Financing Highway Improvements, on Traffic Studies, and on Organization of Construction Plants are under consideration.

Professor Hatt, in consultation with the Advisory Board, will prepare a comprehensive plan of the field of highway research, including economics, design, construction and administration, and will arrange a program of committee work for those fields that need to be occupied immediately.

N.E.L.A. Issues Reprints of Prime Movers Committee Report

The Prime Movers Committee of the National Electric Light Association presented a comprehensive report at the recent Chicago Meeting of the Association. The functions of the Committee are the investigation and reporting of developments in design, installation, and operation of prime movers and equipment for the production of power from fuel for the generation of electricity.

This report, a book of 350 pages, contains considerable information about the various types of new equipment which have been developed and placed in use. The statements of users and manufacturers are given concerning each class of equipment. A bibliography is also provided for those who wish to get more complete information. The demand proved to be so great that the N.E.L.A. has authorized the reprinting of the report. Copies are on sale at the Association headquarters, 29 West 39th St., New York, N. Y.

September Board Meeting to be Held at Washington

THE next meeting of the Executive Board of the American Engineering Council will be held at the Cosmos Club in Washington on September 30. This will be the first meeting of the Board in Washington since its initial meeting held there November 20, 1920. It is probable that the Board will decide at this meeting whether it will hold future meetings regularly at the Washington headquarters or will pursue the plan of meeting at various engineering centers throughout the country as it has been doing during the past year.

The most important business coming before the September meeting will be the election of a president to succeed Herbert Hoover, who resigned after he became Secretary of Commerce. Nominations to fill this vacancy were ordered at the last meeting of the Executive Board, held at St. Louis on June 3. Other items which have been before the Board will come up for further consideration, special attention being given to the plans for the Engineering Assembly, the extension of the Employment Service, and the question of licensing and registration of engineers.

Employment Service Conducts Special Work

In regard to Employment Service extension the Finance Committee has made arrangements to increase the budget of the Employment Service so that special emergency work can be done for the large number of engineers now out of employment. Prominent engineers, manufacturers and bankers throughout the country will be canvassed by letter for the purpose of compiling information on vacant positions. Special committees of engineers will call on prospective employers as much as possible throughout the states.

In New York City a volunteer committee of twelve has been engaged in this work since late in May. In spite of the fact that the vacation period and changed addresses and business connections have materially delayed the work, a report of this committee submitted on August 15 shows that over 1600 calls have been made 1000 interviews granted, 36 positions found, and 59 prospective positions listed. Practically all of the technical journals, allied journals and periodicals read by engineers and captains of industry have been called upon and a number of editorials have already been published. Slightly over 300 new calls and some return calls remain to be made in New York City proper. A classification of members by companies in the commuting area of the city (outside of Manhattan) is well under way and recommendations may be made on the organizing of one or more committees to cover that area.

The special Employment Committee of the Council is working in conjunction with the Employment Management Committee in developing further plans for the Service.

Engineering Assembly Planned for January

The Engineering Assembly Committee has been appointed as follows:

A. P. Davis, Washington, D. C., *Chairman*
Philip N. Moore, St. Louis, Mo.
L. P. Alford, New York, N. Y.
John C. Hoyt, Washington, D. C.
F. A. Vaughn, Milwaukee, Wis.

This committee will work out detailed plans for an assembly to be held in conjunction with the annual meeting of the American Engineering Council, the assembly having been authorized by the special vote of the Executive Board at its Philadelphia meeting in April. Present plans are to make this assembly a three-day session during the latter part of January 1922. One day will probably be devoted to special meetings of the Executive Boards of member organizations and committees of the Council, one to sessions of the Council, and one to the discussion of some special topic such as elimination of waste, licensing of engineers, the National Department of Public Works, or some other subject of equal importance to the engineering profession.

Committee Work of Council Varied and Important

The Committee on Procedure and the Committee on Public Affairs have been of great assistance in carrying on the work of the Council. Under their direction the Council has been active in advancing the plans for a National Department of Public Works, improving the status of public health engineers, obtaining equitable engineering research legislation, coöperating with the American Engineering Standards Committee, working for the appointment of engineers to engineering positions in the Federal Government, supporting the topographic mapping program and much-needed patent legislation, etc.

The most important committee work of the Council during recent months has been the study of Elimination of Waste in Industry. An abstract of the report of this committee will be found elsewhere in this issue. Copies of the complete report will be available shortly and may be secured from L. W. Wallace, Secretary of the Federated American Engineering Societies, 719 Fifteenth St., N. W., Washington, D. C.

Engineering and Industrial Standardization

Results of the Last Three Years' Work of the Joint Committee on Steel Roller Chains Shown by Report on Standards Developed

FROM time to time since its organization in July 1917, the Joint Committee of the Society of Automotive Engineers and The American Society of Mechanical Engineers has made progress reports. Now, however, we are able to publish the standards which it has developed for (1) Roller Transmission Chain Dimensions, Heavy, Medium and Light Series; (2) Roller Transmission Chain Sprockets; (3) Tooth Forms for Roller-Chain Sprockets and corresponding cutter design; and (4) Uniform System for Numbering Chains.[1]

As its work has progressed, the Joint Committee has kept constantly in touch with the work of the Association of British Driving Chain Manufacturers with a view to the final adoption of standards which would receive international approval. Consequently certain concessions have been made on both sides and the standard dimensions given below are the same, with a very few exceptions, as those adopted by the A.B.D.C.M.

Roller Transmission Chains—Heavy Series

The "chain widths" given in Column 5 of Table 1 are for the wide-chain series. The numbers express the exact distance between the inside plates and are as near to the norm of $W = {}^5/_8 P$ as seems advisable in consideration of present practice and the desire to express dimensions in terms of binary fractions. These are known as "wide" chains.

The Committee also recognizes as standard a narrow class of chains for which $W = 0.41\ P$, but recommends only the wide series for general practice. These narrow chains can be made in all three series, heavy, medium and light.

Roller Transmission Chains—Medium Series

The standard medium-weight series of roller transmission chains is developed by adopting for each pitch the standard rollers, bush-

[1] Standards (1) and (2) were presented to the A.S.M.E. at the Spring Meeting held in May, 1921, in Chicago and were adopted. Standards (3) and (4) will be presented to this Society for adoption in December, 1921. The S.A.E. has already adopted the entire set.

ings, and pins of the next shorter pitch and assembling them with side plates equal in thickness to those of the next shorter pitch of the heavy series.

Roller Transmission Chains—Light Series

The standard light-weight series of roller transmission chains is developed by adopting for each pitch the standard rollers, bushings, and pins of the second shorter pitch and assembling them with side plates equal in thickness to those of the second shorter pitch of the heavy series.

TABLE 1 DIMENSIONS OF ROLLER TRANSMISSION CHAIN, HEAVY SERIES, IN INCHES

Pitch	Roller Diameter	Pin Diameter	Thickness of Inside Plates	Chain Width, Min. (W[1])	Measuring Load, Lb.	Approx. Test Load, Lb.
3/8	0.250	0.125	0.050	0.250	14	464

1 3/4	1.040 ±0.013	0.525	7/32	0.021	0.085
2	1 156 ±0.015	0.600	1/4	0.024	0.094
2 1/2	1 447 ±0.018	0.750	5/16	0.030	0.115
3	1 738 ±0.021	0.900	3/8	0.036	0.137
4	2.319 ±0.027	1.200	1/2	0.048	0.181
5	2 784 ±0.032	1.500	5/8	0.060	0.216
Formulas	T = 0.93W − 0.006 Tolerances = ±(0.01W + 0.002)	0.3P	P/8	0.012P	0.07W + 0.006

All dimensions in inches.

By thus setting the five principal dimensions of the chain for each of the thirteen pitches in each of the three series, the Committee has done all that is necessary to insure the interchangeability of spare links between chains of various makes and also the interchangeability between chains and sprockets.

Tolerance for Chain Length. New chains under standard measuring load may be one sixty-fourth inch per foot over length, but must not be under length.

Roller Transmission Chain Sprockets

Table 2 and its accompanying figure give in convenient form the standard dimensions of chain sprockets as far as width, clearance and transverse sections are concerned.

Roller Transmission Chain Sprocket-Tooth Form and Sprocket-Tooth Cutters

Historical Note. The first tooth forms for roller-chain sprockets were designed upon the theory that the tooth action was similar to that of gear teeth, the chain being regarded as analogous to a rack. It was, however, soon found that when chains had been in use a short time the wear at the joints caused an elongation of the pitch of the chain, thus destroying perfect registration with the sprocket teeth which resulted in rough action and rapid wear. The sprocket teeth were then redesigned to provide for the chain elongation by making the tooth gap somewhat greater than the diameter of the chain roller, but with little or no modification in the contour of the tooth, which was so shaped that the chain roller bore almost squarely against the sprocket tooth, throwing practically the whole load on a single tooth.

Meanwhile, the use of roller chains became more extensive and the demands made on them more exacting. This condition naturally led, both in this country and abroad, to a more careful study of the action between chains and sprocket teeth than had heretofore been given to the subject, and it soon became apparent that by giving some obliquity to the face of the sprocket tooth, quite different and decidedly better results could be obtained. The action of the forces called into play can be readily analyzed by the graphic method of laying out a parallelogram of forces which will show in true proportion the initial tension on the chain, the resultant thrust on the sprocket tooth (determined by the degree of obliquity selected) and a balancing force passed on to the ensuing links of the chain where this action is repeated in a lessening amount.

By this method the load on a chain may be distributed over several teeth of the sprocket and at the same time, by extending the oblique portion of the sprocket tooth a suitable distance, make it possible for a chain of elongated pitch to slide outward on this oblique face until it finds a pitch circle on the sprocket coinciding with the lengthened pitch of the chain. These general findings were freely exchanged among the chain manufacturers and one of the English companies published a brochure on the subject. During the war more pressing matters prevented an interchange of opinion on this subject, but never the less most of the sprocket manufacturers evolved tooth forms along these lines.

It is now proposed to effect an agreement upon one standard form that shall supersede the various individual designs, and the formula now presented by the Joint Committee for adoption is a composite of the best features of the various tooth shapes that have been tried out and pronounced satisfactory.

Sprocket Tooth Form (See Fig. 1)

P = pitch of chain
D = nominal roller diameter
N = number of teeth in sprocket
D' = diameter of seating curve = 1.005 D + 0.003 in.

$$A = 31° + \frac{90°}{N}$$

$$ws = 0.8\,D$$

$$B = 13° - \frac{18°}{N}$$

xz = a circular arc whose center is at w
zy = a straight line perpendicular to wz

$$xy = 1.3\,D \times \sin\left(25° - \frac{90°}{N}\right)$$

ek = a line perpendicular to st

H = height of tooth crest above the chord $se = 0.35\ P$

qy = a line parallel to wz with q so located that the circular arc through y will pass through k, thus forming a pointed tooth.

Outside Diameter of Sprocket = Pitch Diameter +

$$P\left(0.7 - \tan\frac{90°}{N}\right) = \text{(approx.)}\ P.D. + P\left(0.7 - \frac{1.592}{N}\right)$$

$$E = O.\ D. \times \sin\frac{180°}{N}$$

Sprocket-Tooth Cutters (See Fig. 2)

Cutters shall be designed for 6, 7-8, 9-11, 12-17, 18-34, 35 teeth and over.

The number of teeth on which each cutter shall be based is, $M = \frac{2\ N\ n}{N+n}$, where N and n are the maximum and minimum number of teeth to be cut by any given cutter. A sprocket having N teeth will thus have a pressure angle which departs the same amount from the desired pressure angle as one having n teeth.

The values of M for the various cutters are respectively, 6, 7.47, 9.90, 14.07, 23.54 and 65.42 teeth.

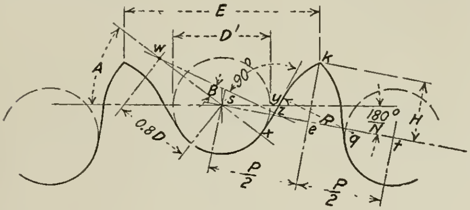

Fig. 1

Cutter numbers shall be respectively, 6, 7½, 10, 14, 24 and 65.

$D' = 1.005\ D + 0.003$ in.

$A = 31° + \frac{90°}{M}$

$ws = 0.8\ D$

$B = 13° - \frac{18°}{M}$

xz = a circular arc with w as the center

zy = a straight line perpendicular to wz

$xy = 1.3\ D \sin\left(25° - \frac{90°}{N}\right)$

$se = \frac{1}{2} P$

$ek = H = 0.35\ P$

yq = a line parallel to wz

q = a point so located that the arc yk, struck from q as a center, will pass through k

The radius R may be determined graphically.

Where the same roller diameter is used on chains of two different pitches (as $^5/_8$-in. roller, 1-in. pitch; and $^5/_8$-in. roller, $1^1/_4$-in. pitch), cutters Nos. 6 and 7½ shall be designed for the longer pitch, and may be used for cutting sprockets of the shorter pitch. Cutters Nos. 10, 14, 24 and 65 shall be designed for the shorter pitch and may be used to cut sprockets of the longer pitch.

W = width of cutter $= 1.02 \times O.\ D. \times \sin\frac{180°}{n}$, to the next higher 32nd inch; where $O.\ D.$ equals the outside diameter of the sprocket with the larger pitch and the lowest number of teeth to be cut with the cutter.

Note: The specifications to the cutter maker may be simplified if w and z are located as follows:

$$a = 0.8 \times D \times \sin\left(31° + \frac{90°}{M}\right)$$

$$b = 0.8 \times D \times \cos\left(31° + \frac{90°}{M}\right)$$

$$xz = 2.6 \times D \times \sin\left(6.5° - \frac{9°}{M}\right)$$

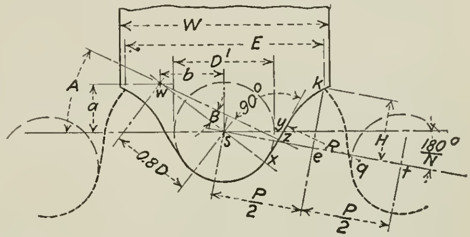

Fig. 2

This proposed standard tooth form and the cutters which produce it have slight modifications from those in general use, but the principles involved have all been thoroughly tried out and the compromises that have been made to produce a standard are in no case large enough to influence the result. Sprocket teeth cut to this form have been in very general use for a number of years.

Standard chains made to fit the old form of sprocket teeth will fit the new form as well, but they will run better on the new sprockets.

Standard Uniform System for Numbering Chains

In this system of numbering, each chain number consists of three parts, the first indicated by the first one or two digits; the second by the last digit, and the third part by the letter which follows the figures. The rule for fixing the number of any standard chain is as follows:

a The left-hand figures shall denote the number of one-eighth ($^1/_8$) inches in the pitch

b The final figure shall denote the series to which the chain belongs. "0" stands for the heavy series, "1" for the medium series, and "2" for the light series

c The letters "W" and "N" following the figures shall denote whether the chain is wide or narrow.

Thus, if the pitch is $^3/_8$ in. and the chain is a wide one of the heavy series, its number is 30W. Again, if its pitch is $1^3/_4$ in. and it is a narrow chain of the medium series, the standard number is 141N.

To provide for rollerless bushing chains the committee proposes the use of the digits 5, 6 and 7 in place of 0, 1 and 2.

LIBRARY NOTES AND BOOK REVIEWS

The Aircraft Handbook. By Fred H. and Henry F. Colvin. Second edition. McGraw-Hill Book Co., Inc., New York, 1921. Cloth, 5 x 8 in., 415 pp., illus., $4.

This work was first published in 1918 under the title, The Aircraft Mechanics' Handbook and was intended to meet the wartime need for a book for airplane mechanics. It has now been thoroughly revised, and increased in scope to meet the needs occasioned by the development of commercial aviation. The book is intended to give a good general knowledge of the principles involved in the design of airplanes and their motors, without describing details, and to show how both planes and motors are assembled, cared for and repaired.

Automaten. By Ph. Kelle. Julius Springer, Berlin, 1921. Cloth, 6 x 9 in., 426 pp., illus., 144 marks.

This work treats of automatic and semi-automatic lathes, screw-machines and similar machine tools. The book first explains the various systems of automatic machinery, and follows this by a detailed discussion of such special parts as driving mechanisms, work holders, feeding devices, gearing and turret heads. Machines

and appliances for special classes of work are also described. The volume is thoroughly illustrated with drawings and photographs of modern German tools.

Automobiltechnisches Handbuch. By Richard Bussien. Tenth edition. M. Krayn, Berlin, 1921. Cloth, 5 x 7 in., 1194 pp., illus., $2.

This pocket-book of automotive engineering is intended primarily for designers and builders, for whom it provides the formulas, technical data, standards and other information usually needed, in convenient form. The first division of the book is given over to general subjects, such as the properties of materials, engine fuels, lubricants, standards, gearing and chain drives. The second division takes up in detail the calculations of mechanical traction, the organs of power transmission, motors, speedometers, electric lighting and starting apparatus, accounting, motor boats, motor plows, fire engines, etc. This edition has been carefully revised.

The Case-Hardening of Steel. By Harry Brearley. Second edition. Longmans, Green & Co., New York, 1921. Cloth 6 x 9 in., 207 pp., illus., $6.

This work, which first appeared in 1914, has been out of print for some years. It is intended for those actively engaged in the commercial manufacture of case-hardened objects, and for this reason is arranged to appeal to the workshop experiences and observation of craftsmen.

Die Drahtseilbahnen. By P. Stephan. Third edition. Julius Springer, Berlin, 1921. Cloth, 6 x 9 in., 459 pp., illus., 150 marks.

This work is presented as a complete treatise on wire ropeways. The first chapter is devoted to a historical account of their development. This is followed by a description of the various details, such as cables, towers, cars and buckets, landing stations and protective devices. Chapter III gives examples of the use of ropeways for transportation in mountainous lands, for river crossings and as conveyors in various industries; while Chapter IV presents the various types. Chapter VI discusses the economic aspects of the subject and legislation. The closing chapter considers erection and operation.

The Efficiency of Pumps and Ejectors. By E. C. Bowden-Smith. D. Van Nostrand and Co., New York, 1920. Cloth, 6 x 9 in., 205 pp., plates, diagrams, $5.

This book discusses their efficiency with regard to a single problem the raising of crude sewage, the author's object being to enumerate and discuss those points which tend to economy, and to suggest methods of increasing efficiency. The problem is treated from three points of view, mechanical efficiency, commercial efficiency and sanitary efficiency.

Engineering Instruments and Meters. By Edgar A. Griffiths. D. Van Nostrand Co., New York, 1921. Cloth, 7 x 10 in., 360 pp., illus., diagrams, $7.50.

The writer has attempted to give a brief review of the appliances which have been devised for the measurement of some of the fundamental quantities of mechanical science, such as length, screw threads, area, volume, velocity, force, mass, work and temperature. The book should enable the reader to appreciate the advantageous and drawbacks of the various types of instruments for making any particular measurement, and to choose the instrument best suited to his requirements. References to literature on the subject accompany each chapter.

Engineering of Power Plants. By Robert H. Fernald and George A. Orrok. Second edition. McGraw-Hill Book Co., Inc., New York, 1921. Cloth, 6 x 9 in., 595 pp., illus., tables, $5.

This is an epitome of the subject arranged for classroom use, in which an especial effort has been made to awaken a realization of the fact that engineering, although based on exact sciences, is not itself an exact science, but requires the application of judgment, and to give the student some idea of the commercial side of engineering. The present edition includes corrections, slight modifications and reasonable additions.

The Engineers and the Price System. By Thorstein Veblen. B. W. Huebsch, Inc., New York, 1921. Cloth, 5 x 8 in., 169 pp., $1.50.

Contents: On the Nature and Uses of Sabotage; The Industrial System and the Captains of Industry; The Captains of Finance and the Engineers; On the Danger of a Revolutionary Overturn; On the Circumstances which Make for a Change; A Memorandum on a Practical Soviet of Technicians.

This series of papers is reprinted from the *Dial*, where they appeared during 1919. They discuss certain difficulties involved in the American industrial situation, and present the author's views concerning the way in which they will be solved.

Foundrywork. By Ben Shaw and James Edgar. Sir Isaac Pitman & Sons, Ltd., London and New York, 1921. (Pitman's technical primer series.) Boards, 4 x 6 in., 115 pp., illus., $1.

This book is intended to supply engineers responsible for the designing machines that involve castings with some knowledge of the fundamental principles applied to their production in the foundry, in order that the difficulties involved in the casting of intricate forms may be understood by the designer and avoided in the design when possible.

Gasoline and Other Motor Fuels. By Carleton Ellis and Joseph V. Meigs. D. Van Nostrand Co., New York, 1921. Cloth 6 x 9 in., 709 pp., diagrams, $10.

The authors of this work have endeavored to prepare a substantially complete survey of the field, which would include a description of practically every process of making gasoline and of most other motor fuels of prominence or promise. The chief fuels considered are gasoline, benzene, alcohol and shale and asphalt oils. Much attention has been given to patent literature.

Handbuch des Wasserbaues. By Hubert Engels. Second edition. Wilhelm Engelmann, Leipzig, 1921. 2 vol., 7 x 11 in., diagrams.

The first edition of Engels' Handbuch des Wasserbaues, published in 1914, was intended to meet the lack of a modern work covering the entire field of hydraulic engineering in a uniform manner. The second edition has been revised and enlarged.

The work is divided into ten sections treating of the occurrence and movement of water, hydrology, river works, weirs, dams and water-power plants, protection of land, agricultural hydraulic works, navigation, ship locks, river canalization and ship canals, and harbors. Each of these is an extensive summary of modern theory and practice, accompanied by a list of "sources."

The High Cost of Strikes. By Marshall Olds. G. P. Putnam's Sons, New York, 1921. Cloth, 6 x 8 in., 286 pp., $2.50.

In this book the author has attempted to analyze the costs to the public and to labor itself of the strike epidemic which followed the war and to show, as concretely as possible, the results, to labor and the whole country, of the theories of the professional labor leader as they become apparent in this large-scale demonstration. He endeavors to make clear the wasteful absurdity of strikes as a means of controlling the division of the proceeds of production, and suggests other measurements for adjusting labor questions.

Industrial Organization and Management. By Hugo Diemer. La Salle Extension University, Chicago, 1921. Cloth, 6×8 it., 291 pp., illus., $3.

Contents: The Principles of Business Organization; Types of Organization; Locating an Industry; Manufacturing Plants and Equipment; Buying; Receiving, Storing, and Recording Materials; Planning; The Determination of Costs; Methods of Collecting Material and Labor Costs; The Distribution of the Expense Burden; Standardization; Scientific Management; Time and Motion Studies; Wage Systems; Welfare and Betterment Work; Employment Problems; Reports to Executives.

The contents illustrate the general purpose and scope of this book. The volume is intended for beginners and sets forth the elements of the subject clearly and concisely.

The Manufacture of Pulp and Paper. Volume 2. By J. J. Clark and T. L. Crossley. First edition. McGraw-Hill Book Co., Inc., New York, 1921. Cloth, 6 x 9 in., 182 pp., illus., $5.

This is the second volume of the series of textbooks prepared under the direction of the educational committees of the pulp and paper associations of the United States and Canada, as a course of study bringing together the fundamental facts of mathematics and elementary science and the principles and practice of paper and pulp making. The present book is devoted to mechanics, hydraulics, elementary electricity and chemistry. It is adapted for home study as well as for classroom instruction.

THE ENGINEERING INDEX presents each month, in conveniently classified form, items descriptive of the articles appearing in the current issues of the world's engineering and scientific press of particular interest to mechanical engineers. At the end of the year the monthly installments are combined along with items dealing with civil, electrical, mining and other branches of engineering, and published in book form, this annual volume having regularly appeared since 1906. In the preparation of the Index by the engineering staff of The American Society of Mechanical Engineers some 1200 technical publications received by the Engineering Societies Library (New York) are regularly reviewed, thus bringing the great resources of that library to the entire engineering profession.

Photostatic copies (white printing on a black background) of any of the articles listed in the Index may be obtained at a price of 25 cents per page, plus postage. A separate print is required for each page of the larger periodicals, but wherever possible two small or medium-sized pages will be photographed together on the same print. The bill will be mailed with the print. When ordering photostats identify the article by quoting from the Index item: (1) Title of article; (2) Name of periodical in which it appeared; (3) Volume, number, and date of publication of periodical; (4) Page numbers. Orders should be sent to the Engineering Societies Library, 29 West 39th Street, New York.

ACCIDENT PREVENTION

Building Construction. Prevention of Accidents in the Erection of Steelwork. Contract Rec., vol. 35, no. 25, June 22, 1921, pp. 605–608. Instructions issued by construction firm to its foremen engaged in placing of structural steel. Rules governing handling of erection equipment and tools.

AERODROMES

Design. The Effect of Temperature and Altitude of Aerodrome in the Taking off of Aeroplanes, P. G. Gundry. Aeronautical Jl., vol. 25, No. 126, June 1921, pp. 290–300, 7 figs. Design of aerodromes suitable for conditions in South Africa. Paper read before South African Assn. for Advancement of Science.

AERONAUTICAL INSTRUMENTS

Steering Gages. German Gyro Gauges, Alfred Gradenwitz. Aeronautics, vol. 20, no. 401, June 23, 1921, pp. 451–452, 3 figs. Description of Drexler aircraft steering gage fitted on large fighting aeroplanes of German army.

AEROPLANE ENGINES

ABC Wasp. Standard Engine Report on ABC Wasp Radial Aeronautical Engine Rated at 170 Hp. at 1800 R.P.M. U. S. War Dept., Air Service Information Circular, vol. 2, no. 197, April 30, 1921, 23 pp., 26 figs. Results: Normal hp. full throttle, 169.5 at 1800 r.p.m.; fuel consumption at normal hp., 0.592 lb. per hp-hr. at 1800 r.p.m.; brake m.e.p. at normal speed, 111.2 lb. per sq. in. at 1800 r.p.m.; total dry weight, 289.15 lb.; dry weight per hp., 1705 lb.

Developments. The Requirements of Aeronautic Powerplant Development, G. J. Mead and L. E. Pierce. Jl. Soc. of Automotive Engrs., vol. 9, no. 1, July 1921, pp. 23–32, 2 figs. Review of developments of various engine types, analysis of effect of their characteristics on aeroplane performance and consideration of proper installation of powerplants in aeroplane.

French. French Aeroplane Engines in 1920 (Les moteurs d'aviation français en 1920), M. Martinot-Lagarde. Aéronautique, vol. 3, nos. 19–20, Jan. 1921, pp. 296–305, 11 figs. Panhard-Levassor, Schneider, Renault, Salmson, Bréguet, Henri-Paul and Rhône.

Fuels. The Use of Commercial Low-Test Automobile Gasoline in Aviation Engines. U. S. War Dept., Air Service Information Circular, vol. 3, no. 216, April 30, 1921, 12 pp., 6 figs. With commercial low-test automobile gasoline power developed was 7 per cent less at normal speed than that obtained with domestic aviation gasoline. With mixture of low-test automobile gasoline and 6 per cent xylidine by volume, 5-hr. run with regular operation was obtained.

Heaters. Test of Airplane Engine Heater. U. S. War Dept., Air Service Information Circular, vol. 3, no. 232, May 25, 1921, 4 pp., 2 figs. Object of test was to determine possible cause of unsatisfactory service rendered by engine heaters.

Manifold. Eliminating Crankcase Dilution by Manifold Development, G. P. Dorris. Jl. Soc. of Automotive Engrs., vol. 9, no. 1, July 1921, pp. 35–36, 4 figs. Type of manifold in which admission pipe is cast integrally over exhaust pipe. Exhaust ports form hot spot immediately above carburetor inlet.

Starting Switches. Operating Tests of Magnetically Operated Starting Switches U. S. War Dept., Air Service Information Circular, vol. 3, no. 214, April 30, 1921, 6 pp., 6 figs. Bijur switch was found unsatisfactory. Hart switch, U. S. L. switch and Diamond-H switch proved satisfactory for production.

Supercharging. An Analysis of the Effect of Supercharging. U. S. War Dept., Air Service Information Circular, vol. 2, no. 195, April 15, 1921, 11 pp., 8 figs. Analysis of typical performance of aeroplane fitted with supercharging device.

Some Experiments on Supercharging in a High Speed Engine, Harry R. Ricardo. Automobile Engr., vol. 11, no. 151, June 1921, pp. 219–224, 20 figs. Comparative graphic study of performance with supercharging device and normal.

AEROPLANE PROPELLERS

Wheel. Wheel Propeller for Aircraft. Aeronautics, vol. 20, no. 399, June 9, 1921, p. 414, 6 figs. Patented wheel propeller built in such a manner that number of wing planes placed in vicinity of periphery of wheel and parallel to wheel axis, adjust themselves during rotation of wheel and become active only during half revolution of wheel, while during other half of revolution of wheel their position will be tangential to wheel.

AEROPLANES

Aerofoils. Airfoil Data on American and British Airfoils. U. S. War Dept., Air Service Information Circular, vol. 2, no. 197, April 30, 1921, 129 pp., 63 figs. Tables of coefficients and graphs of angle of incidence for 32 American models and 32 British models.

All-Metal. The All-Metal Aeroplane in Germany (L'avion métallique en Allemagne), Roger Couturier. Aéronautique, vol. 3, no. 24, May 1921, pp. 194–200, 9 figs. Junkers types.

Corrosion of Metal Parts. Methods for Preventing the Corrosion of Metal Parts of Aeroplanes. Aerial Age, vol. 13, no. 16, June 27, 1921, pp. 369–370, 1 fig. Graph giving results of comparative experiments on lasting qualities of various protecting methods. Air Service Information Circular.

Preliminary Report on Investigation of Methods for Preventing the Corrosion of Metal Parts of Airplanes. U. S. War Dept., Air Service Information Circular, vol. 3, no. 211, April 30, 1921, 4 pp., 1 fig. Corol compound was found to be best organic corrosion preventative. Zinc plating, it was determined, offers best protection against corrosion of metallic coatings tested.

Design. Some Possible Refinements in Design, W. R. Douglas Shaw. Aeronautics, vol. 20, no. 401, June 23, 1921, pp. 453–454, 10 figs. Suggestions in regard to airscrew distribution, balanced ailerons, wing section and seating accommodation.

The Loads and Stresses in Aeroplanes, John Case. Aeronautics, vol. 20, no. 402, June 30, 1921, pp. 475–477, 6 figs. Model experiments with elevators of different sizes. (Continuation of serial.)

French Commercial Types. New French Commercial Airplanes. Aviation, vol. 11, no. 2, July 11, 1921, pp. 48. Spad-33 6-Seater and Potez-IX 5-Seater.

Performance. Airplane Performance and Design Charts, L. V. Kerber. Aviation, vol. 10, nos. 24 and 25, June 13 and 20, 1921, pp. 748–751, 2 figs., and 780–784, 15 figs., June 13: Graphical solution of empirical-theoretical method of predicting performance of aeroplane of which are known weight, area, horsepower and external characteristics; also method for determining weight and area of aeroplane of given horsepower and external characteristics which is to be designed to realize a required performance. June 20: Charts for computing rate and time of climb for aeroplanes fitted with Liberty 12, Hispano-Suiza and similar engines.

Steady Motion, Theory of. General Theory of the Steady Motion of an Airplane, George de Bothezat. Nat. Advisory Committee for Aeronautics, report no. 97, 1921, 70 pp., 27 figs. Development of chart representing aeroplane steady-motion performance.

Wings. Ground-Plane Influence on Airplane Wings, A. F. Zahm and R. M. Bear. Aviation, vol. 10, no. 26, June 27, 1921, pp. 807–808, 5 figs. Test made on single British R.A.F. 6 aerofoil at 40 m.p.h. in wind tunnel at Washington navy yard. From Jl. Franklin Inst.

The Handley Page Wing. Aeronautical Jl., vol. 25, No. 126, June 1921, pp. 263–278 and (discussion) 279–289, 31 figs. Record of experimental work carried out with a view to overcoming phenomenon of "burbling."

Stresses. The Deflection of Supporting Planes and Stress of Material (Tragflächendurchbiegung und Stoffbeanspruchung), A. Pröll. Zeit. für Flugtechnik u. Motorluftschiffahrt, vol. 10, no. 11–12, June 28, 1919, pp. 121–124, 6 figs. Calculation of increase of stress due to deflection of supporting planes.

Zeppelin Passenger. The 1000-Hp. Passenger Aeroplane of the Zeppelin Works in Staaken (Das 1000 PS-Verkehrsflugzeug der Zeppelinwerke in Staaken), Ad. K. Rohrbach. Zeit. des Vereines deutscher Ingenieure, vol. 65, no. 23, June 4, 1921, pp. 591–594, 12 figs. Monoplane, designed by author and made entirely of duralumin, reached on trial flight a speed of 211 km. per hr. with engines somewhat throttled. The four 260-hp. Maybach engines are placed side by side on wing.

AIR COMPRESSORS

Hydraulic. Experiences in Construction and Operation of Hydraulic Compressors in the Harz (Germany) (Bau- und Betriebserfahrungen mit Hydrokompressoren im Harz), K. Rubach. Glückauf, vol. 57, no. 16, Apr. 16, 1921, pp. 361–367, 9 figs. Development of theory of hydraulic compressors and operating experiences, based on which suggestions are drawn for their constructional arrangement. Future possibilities of their use.

Small. A Small Compressor (Klein-Kompressor), M. Prölss. Chemiker-Zeitung, vol. 45, no. 27, Mar. 3, 1921, p. 220, 3 figs. Small air compressor exhibited at Leipzig fall exhibition, constructed in four sizes for supplying 3, 10.6, 12.7, and 29.5 cu.m. of air per hour at pressure of 6 atmos. Advantages of its use in laboratories, repair workshops, etc.

AIR LIFT

Raising Liquids. Compressed-Air Lifts for Raising Liquids, A. T. Cross. Mech. World, vol 69, No. 1798, June 17, 1921, pp. 462–463, 3 figs. Formulas and graphs for computing efficiency of installation.

Characteristics: Length, 695 ft.; diameter, 85 ft. 4 in.; capacity, 2,700,000 cu. ft.; total normal lift, 83 tons; disposable lift, 50 tons; endurance at full speed, 5000 mi.; estimated ceiling, 25,000 ft.

ZR.2. "ZR.2" ("R.38"). Flight, vol. 13, no. 23, June 9, 1921, pp. 287–289, 6 figs. Characteristics; Length, 695 ft.; diameter, 85 ft. 4 in.; capacity 2,700,000 cu. ft.; total lift under normal conditions, 83 tons; total horsepower, 2100.

ALCOHOL

Industrial. Industrial (Including Power)—Alcohol Charles H. Bedford. Jl. Royal Soc. of Arts, vol. 49, no. 3577, June 10, 1921, pp. 472–482 and (discussion) pp. 482–486. Possibilities of establishing within British Empire industrial alcohol industry.

Industrial Alcohol and Prohibition Enforcement Chem. & Metallurgical Eng., vol. 24, no. 25, June 22, 1921, pp. 1088–1093. Before Committee on Industrial Alcohol, Am. Chem. Soc. Administration and enforcement of existing law are denounced.

Industrial Alcohol (L'alcool industriel), Charles Blanchet. Revue de l'ingenieur et Index Technique, vol. 28, no. 5, May 1921, pp. 211–219. Economics of alcohol synthesis from acetylene. (Concluded.)

ALCOHOL ENGINES

Tests. Tests with Alcohol Engines (Undersökningar å Spritmotorer), E. Hubendick. Teknisk Tidskrift (Mekanik), vol. 51, nos. 2, 3 and 4, Feb. 9, Mar. 9, and Apr. 13, 1921, pp. 25–31, 45–52 and 69–73, 23 figs. Comparison of efficiency and weight of engines for alcohol and for gasoline with same dimensions and same power. Basic principles of design. Results of tests show degree of compression to be from 7 to 9 for alcohol alone or mixed with gasoline or benzol. In spite of high degree of compression, output remains practically unchanged. Alcohol engines with flywheel are 20 per cent heavier than gasoline engines and 15 per cent dearer. Denaturing of alcohol.

ALLOY STEELS

Tests. Comparative Tests of Steels at High Temperatures, R. S. MacPherran. Chem. & Metallurgical Eng., vol. 24, no. 26, June 29, 1921, pp. 1153–1155, 13 figs. Determination of comparative properties of various alloy steels at high temperatures with a view to obtaining information as to best material for use under operating conditions of 600 to 1000 deg. fahr. It was found that introduction of metals forming carbides tends to strengthen steels at high temperatures. Paper read before Am. Soc. for Testing Matls.

ALLOYS

Microstructure. Micrographic Study of Alloys and of the Structure of Tungsten Steels by Their Slow Cooling (L'emploi des refroidissements très lents pour l'étude micrographique des alliages et la structure des aciers au tungstène), A. Portevin. Comptes rendus des Séances de l'Académie des Sciences, vol. 172, no. 61, April 18, 1921, pp. 964–967, 2 figs. Record of experiments.

[See also BEARING METALS; COPPER ALLOYS; IRON ALLOYS; MONEL METAL; NON-FERROUS METALS.]

ALUMINUM

Casting Losses. Losses in Aluminum and Aluminum-Alloy Melting, Robert J. Anderson. Brass World, vol. 17, no. 6, June 1921, pp. 154–156. Method of estimating metal and fuel losses in melting aluminum.

ALUMINUM ALLOYS

Melting Losses. Aluminum-Alloy Melting Loss Great, Robert J. Anderson. Foundry, vol. 49, no. 13, July 1, 1921, pp. 520–522. Description and estimation given of losses sustained in melting aluminum and aluminum alloys. Oxidation and heavy fuel consumption due to inefficient furnace operation principal causes. Report prepared for United States Bureau of Mines.

Reverberatory Furnaces. Aluminium and Its Alloys in Engineering—V, John G. A. Rhodin. Engr., vol. 131, no. 3414, June 3, 1921, pp. 586–589, 4 figs. Description of aluminum reverberatory furnaces.

Uses. Aluminium and Its Alloys in Engineering, John G. A. Rhodin. Engr., vol. 131, nos. 3415 and 3416, June 10 and 17, 1921, pp. 622–623 and 635–636. June 10: Behavior of aluminum castings. June 17: Principles of designing dies for facilitating their use in the foundry.

AMMONIA

Properties. The Isometrics of the Ammonia Superheated Region and the Vapor Pressure of Liquid Ammonia, Frederick G. Keyes. A.S.R.E. Jl., vol. 7, no. 5, Mar. 1921, pp. 371–379, 1 fig. Experiments at research laboratory of Mass. Inst. of Technology.

APPRENTICES, TRAINING OF

Railways. A Railway Company's System of Engineering Apprenticeship. Eng. & Indus. Management, vol. 5, no. 24, June 16, 1921, pp. 692–694. Practice of Orleans Ry. Co. Translated from Revue générale des Chemins de Fer.

Systems. Apprenticeship System of the Southern Pacific Railway, Frank A. Stanley. Am. Mach., vol. 55, no. 1, July 7, 1921, pp. 12–15, 8 figs. Methods of instruction. Rates of pay while learning. Summary of periods of instruction.

Programs of Apprenticeship and Special Training in Representative Corporations, J. V. L. Morris. Am. Mach., vol. 54, no. 25, June 23, 1921, pp. 1081–1083, 1 fig. Plan of instruction followed in plant of Westinghouse Air Brake Co., Wilmerding, Pa.

ARTILLERY

Anti-Aircraft. The future of Anti-Aircraft Artillery, Robert V. Morse, Jl. U. S. Artillery, vol. 54, no. 6, June 1921, pp. 583–593, 3 figs. Future developments.

AUTOGENOUS WELDING

Low-Carbon Steel. The Influence of Foreign Substances in Low-Carbon Steel on Its Weldability in Melting Flame (Ueber den Einfluss der Fremdkörper im Flusseisen auf seine Schweissbarkeit in der Schmelzflamme), C. Diegel. Zeit. des Vereines deutscher Ingenieure, vol. 65, no. 24, June 11, 1921, pp. 626–629, 5 figs. Influence of C, Si, Mn, P and S in low-carbon steel on quality of seam with autogenous welding. Results so far of tests being carried out by Julius Pintsch Corp. show injurious influence of silicon.

AUTOMOBILE ENGINES

Air-Cooled. Fins for Air-Cooled Engines. Automobile Engr., vol. 11, no. 151, June 1921, p. 213, 1 fig. Formulas for determining dimensions of fins.

Gas-Producer Plant. Suction Gas-Producer Plant for Motor Vehicles. Engineering, vol. 111, no. 2894, June 17, 1921, pp. 739–741, 18 figs. Parker plant manufactured by Producer-Gas Plants, of London.

High-Compression. Developing a High-Compression Automotive Engine, Fred C. Ziesenheim. Jl. Soc. of Automotive Engrs., vol. 9, no. 1, July 1921, pp. 5–19, 16 figs. Experimental work in development of mechanical injection system conducted at Carnegie Inst. of Technology, Pittsburgh.

Manifold Design. Intake Manifold Practice in Europe, W. F. Bradley and S. Gerster. Automotive Industries, vol. 44, no. 25, June 23, 1921, pp. 1370–1375, 41 figs. Based mainly on French practice.

Pistons. A Novel Piston. Automobile Engr., vol. 11, no. 151, June 1921, pp. 212–213, 4 figs. Allen design, aiming at minimum ring friction and even pressure.

Research. A Suggested Programme for Automobile Research, Geo. W. Watson. Automobile Engr., vol. 11, no. 151, June 1921, pp. 225–230. Utilization of low-grade fuel; alcohol, ether, benzol, and mixtures thereof; and solid fuels. Study of materials for valves, and design of pistons, piston rings and cylinders; cooling systems; silencers; lubrication; shafts; bearing metals; gears; spring suspension; brakes and transmission.

Vibrating Force. Running Balance and Uniformity of Crankshaft Effort in 8-Cylinder 60 Degree Vee Engines, P. M. Heldt. Automotive Industries, vol. 44. no. 26, June 30, 1921, pp. 1427–1429, 4 figs. Analytical study of vibrating forces in 8-cylinder Vee engine. One conclusion reached is that maximum vibrating force of 60 deg. eight-cylinder engine is only 61.2 per cent of that of 90 deg. 8-cylinder Vee engine.

AUTOMOBILE FUELS

Benzol. Nearly 65 Miles on One Gallon of Benzol, W. F. Bradley. Automotive Industries, vol. 44, no. 25, June 23, 1921, pp. 1364–1365, 2 figs. New record is established in French "grand prix" fuel-consumption test by Gregoire, Citroen and other small cars, as well as by some larger cars. Nearly all makes entered in 183-cu. in. class and smaller make over 30 m.p.h.

Research. Influence of Various Fuels on Engine Performance—IV, H. R. Ricardo. Automotive Industries, vol. 45, no. 1, July 7, 1921, pp. 8–13 and 17, 6 figs. When all fuels are used with same compression ratio, power output is proportional to energy content of charge, but fuels which can be used with higher compression ratios without detonation are capable of developing higher maximum power than those which detonate at lower pressures. From Automobile Engr.

Where Are We Getting in Efforts to Solve the Fuel Problem? Herbert Chase. Automotive Industries, vol. 44, no. 24, June 16, 1921, pp. 1241–1250, 15 figs. Review of research and development work covering results of tests and improvements in design made public during past year, together with comments on future developments that appear to be promising.

[See also AEROPLANE ENGINES, Fuels; BENZOL.]

AUTOMOBILES

Body Suspension. A New Method of Automobile Body Suspension, George J. Mercer. Automotive Industries, vol. 44, no. 24, June 16, 1921, pp. 1261–1263, 4 figs. There are two supports on each side for connecting body to frame and body sills are outside frame.

Examples of European Practice in Three- and Four-Point Suspension, M. W. Bourdon. Automotive Industries, vol. 44, no. 26, June 30, 1921, pp. 1419–1420, 6 figs. Tendency is toward three-point type, though majority of cars still employ four-point arrangement. One maker employs self-aligning ball bearing as support for extended front end of crankcase.

Propulsive Suspension of Automobile Body (La voiture a suspension propulsive), Pierre Maréchal. Nature (Paris), no. 2456, April 30, 1921, pp. 279–282, 4 figs. There are no shafts common to wheels on opposite sides, and each of rear wheels is driven by separate mechanism. Body is supported by springs engaging in rod attached to wheel pointing at small angle toward direction of motion. Obstacles force rods against springs, which transmit impact by elasticity to car in direction of motion.

Design in U. S. The Trend of Design in the United States of America. Automobile Engr., vol. 11, no. 151, June 1921, pp. 215–217, 20 figs. Notes on 1921 New York automobile show.

Four-Wheel Brakes. Engineering Analysis of European Four-Wheel Brakes, W. F. Bradley and S. Gerster. Automotive Industries, vol. 44, no. 24, June 16, 1921, pp. 1267–1273, 20 figs. Engineering features of chief types and results of tests.

Front-End Drive. Problems of the Front-End Drive in Automobiles, J. Edward Schipper. Automotive Industries, vol. 44, no. 24, June 16, 1921, pp. 1296–1301, 16 figs. Typical three-wheel Morse silent chain drive. Present and future trend in front-end drive.

Manufacture. Manufacturing Methods on a Light Car. Automobile Engr., vol. 11, no. 151, June 1921, pp. 206–211, 18 figs. Tooling equipment at works of A.B.C. Motors, Ltd., Surrey, England.

Shock Absorbers. Suspension Shock Absorber fo, Automobiles. Sci. Am. Monthly, vol. 4, no. 1r July 1921, pp. 69–70, 5 figs. Construction employing differential lever principle to meet variable conditions.

Starting and Lighting System. Oscillograph Measurements of Instantaneous Values of Current and Voltage in the Battery Circuit of Automobiles, George W. Vinal and C. L. Snyder. U. S. Dept. of Commerce, Technologic Papers of Bur. of Standards, no. 186, May 2, 1921, 23 pp. 28 figs. Oscillograms of instantaneous and average values of current and voltage.

Transmission Gears. A New Transmission Designed to Facilitate Gear Shifting. Automotive Industries, vol. 44, no. 25, June 23, 1921, pp. 1366–1367, 6 figs. Secondary clutch completely disconnects transmission from propeller shaft during interval of gear shafting. Shifting is accomplished by imparting rotary motion to slotted camshaft in gear box which actuates shifting yokes. Shifting lever mounted on steering column.

AVIATION

Civil, Australia. Commercial Aviation in Australia, R. A. Hendy. Aviation, vol. 11, no. 2, July 1921, pp. 49. There are nearly sixty companies or persons engaged independently in aviation.

Civil, Canada. Civil Aviation in Canada. Aviation, vol. 11, no. 2, July 11, 1921, pp. 45, 1 fig. Summary of Canadian civil aviation certificates and licenses issued during 1920 and the first five months of 1921.

Commercial. Commercial Aviation 1920 (La navigation aérienne commerciale en 1920), M. Emile Pierrot. Aéronautique, vol. 3, nos. 19–20, Jan. 1921, pp. 307–316, 8 figs. European developments.

France. French Aviation in 1921, Capt. de Lavergne Aviation, vol. 10, no. 24, June 13, 1921, pp. 745–747. Developments in military and civil aviation.

French Aerial Navigation Regulations. Organization of French Aeronautics. Aerial Age, vol. 13, no. 16, June 27, 1921, pp. 367–368 and 365. Regulations for aerial navigation in France. Establishment of Nat. Meteorological Bur. Note from Nat. Advisory Committee for Aeronautics.

International Law. Aerial Navigation and International Law (La navigation aérienne et le droit international), Henri Bouché. Aéronautique, vol. 3, no. 24, May 1921, pp. 216–220. Study of protocols before French senate. Centrifugal study.

Legislation. Air Navigation Directions—I. Aeronautics, vol. 20, no. 400, June 16, 1921, pp. 442–444. Survey of air-navigation acts enacted from 1911–1919.

London-Paris Service. London-Paris Service. Aeronautics, vol. 20, no. 400, June 16, 1921, pp. 428–431, 3 figs. Report on installation work on engines, oil, water and gasoline systems, engine design, aeroplane design, etc. (To be continued.)

Safety and Economy on the London-Paris Air Service. Flight, vol. 13, no. 24, June 16, 1921, pp. 408–409. Report of committee appointed by Royal Aeronautical Society "to discuss what is required to insure the safe and economical working of an aeroplane carrying mails and passengers between London and Paris.

Radiogoniometry. Aerial Navigation by Radiogoniometry (La navigation aérienne par la radiogoniométrie). Vie technique & industrielle, vol. 2, no. 21, June 1921, pp. 214–217, 8 figs. Operation of radiogoniometry.

Soaring Flight. Soaring and Gliding Experiments in Germany. Stanley Yale Beach. Aviation, vol 11, no. 1, July 4, 1921, pp. 13–14, 2 figs. Records of flights made.

Technique. The Technique of Flight—II, R. M. Hill. Aeronautical Jl., vol. 25, no. 126, June 1921, pp. 301–311, 2 figs. Analysis of longitudinal balance of aeroplane.

AVIATORS

School for Flight Surgeons. Report of the Medical Research Laboratory and School for Flight Surgeons for the Calendar Year 1920. Air Service Information Circular, vol. 3, no. 231, May 20, 1921, 12 pp.

BALANCING

Turbines. Four Years of Balancing Practice, N. W. Akimoff. Jl. Am. Soc. of Naval Engrs., vol. 33, no. 2, May 1921, pp. 261-267, 6 figs. Summary of facts established.

BEAMS

Non-Uniform Section. Deflection of Beams of Non-uniform Section. U. S. War Dept., Air Service Information Circular, vol. 3, no. 213, April 30, 1921, 10 pp., 10 figs. Comparison of graphical and analytical methods of design.

Reinforced-Concrete. Reinforced-Concrete Beams —I, T. C. Broom. Mech. World, vol. 69, no. 1799, July 24, 1921, pp. 484-486, 1 fig. Graph for designing rectangular concrete beam with single reinforcement.

Trussed. The Calculation of Trussed Beams (Zur Berechnung von Fachwerkträgern), L. Gensen. Zentralblatt der Bauverwaltung, vol. 41, no. 44, June 1, 1921, pp. 273-275, 11 figs. Following theorem is derived: The mobility of a biaxial symmetrical link polygon inscribed in a circle is finite.

BEARING METALS

Alloys. Bearing Metals (Ueber Lagermetalle), Bruno Simmersbach. Chemiker-Zeitung, vol. 45, no. 27, Mar. 3, 1921, pp. 216-219. Bronze, white metals and phosphor bronze are said to be best adapted for bearing metals. Review of various patented alloys which have been successfully used.

Self-Lubricating. New Self-Lubricating Bearing Material. Automotive Industries, vol. 45, no. 1, July 7, 1921, pp. 15, 3 figs. Mixture of bronze and graphite developed by General Electric Co.

White-Metal. Some Properties of White Metal Bearing Alloys at Elevated Temperatures, John R. Freeman, Jr., and R. W. Woodward. U. S. Dept. of Commerce, Bur. of Standards, Technologic Papers, no. 188, April 5, 1921, 16 pp., 7 figs. Apparatus for determining yield point and ultimate strength of white-metal bearing alloys at temperatures up to 100 deg. cent. Record of tests.

BEARINGS

Automobile Engines. Automobile Engine Bearings, W. Betterton. Metal Industry (Lond.), vol. 18, no. 24, June 17, 1921, pp. 461-464, 7 figs. Formula for computing dimensions.

BEARINGS, BALL

Types. Comparison of Various Types of Ball Bearings, H. R. Reynolds and R. W. Sellew. Am. Mach., vol. 54, no. 25, June 23, 1921, pp. 1065-1067, 7 figs. Relation between overall width tolerances and radial play mathematically demonstrated. Difference in radial play before and after mounting.

BELT DRIVE

Tension Rollers. Indirect Friction-Disk Drive by Means of Tension Rollers (Tension-Roller Belt Drive) [Indirekter Reibscheibenantrieb durch Druckrollen (Druckrollen-Riementrieb)], H. Schömburg. Der praktische Maschinen-Konstrukteur, vol. 54, no. 10, Mar. 10, 1921, pp. 45-48, 11 figs. Improved tension-roller belt drive patented by Koch & Co. Machine Works, Remscheid-Vieringhausen, Germany.

BENZOL

Specifications. British Standard Specification for Benzol for Motor Fuel. British Eng. Standards Assn., no. 135, Jan. 1921, 9 pp., 3 figs. Defined as liquid consisting essentially of mixture of benzene and not more than 30 per cent by volume of toluene and xylenes.

BLAST-FURNACE GAS

Pressure Regulation. Automatic Gas Regulation with the Aid of the Reineke Regulator (Selbsttätige Gasreglung mit Hilfe des Reglers von Reineke), R. Goetze. Glückauf, vol. 57, no. 8, Feb. 19, 1921, pp. 169-174, 9 figs.

BLAST FURNACES

Design. Designing Hot Blast Stoves, W. E. Groume-Grjimailo. Iron Age, vol. 107, no. 25, June 23, 1921, pp. 1677-1680, 3 figs. Proportioning passes and brickwork of checkers for work they have to do. Combustion and heat-transfer problems.

BOILER FEEDWATER

Degassing. Degassing and Purification of Boiler Feed-Water, Paul Kestoer. Proc. Instn. Mech. Engrs., no. 4, June 1921, pp. 291-330 and (discussion) pp. 330-360, 21 figs. Physical and chemical study of reactions involved. Classification and description of methods.

Purification. Boiler Feed Water Purification, S. B. Applebaum. Chem. and Met. Eng., vol. 25, no. 1, July 6, 1921, pp. 23-26. Outline of respective merits of various methods used for boiler feedwater treatment, with special reference to advantages of Zeolite water-softening process.

BOILER FIRING

Oil Fuel. Liquid Fuel for Steam-Raising, N. A. Anfilogoff. Jl. Soc. Chem. Ind., vol. 40, no. 11, June 15, 1921, pp. 205R-209R, 4 figs. Typical conversion of Babcock and Wilcox boiler to oil fuel without alteration of brickwork.

BOILER OPERATION

Draft Regulator. Wilkins Pressure Regulator. Power, vol. 53, no. 26, June 28, 1921, pp. 1041, 3 figs. Apparatus for draft and stoker control.

Factor of Evaporation. The Calculation of Boiler Performance, W. B. Campbell. Power House, vol.

Heat Balances. Calculating Boiler Heat Balances, H. D. Fisher. Combustion, vol. 5, no. 1, July 1921, pp. 18-24, 7 figs. Graphs.

Water Meters. The Use of Water Meters in Steam-Boiler Operation (Die Verwendung von Wassermessern im Dampfkesselbetriebe). Elektrotechnischer Anzeiger, vol. 38, no. 72, May 7, 1921, pp. 455-457. Details of recent types of open and closed water meters, both of which systems are said to give good results.

BOILERS

Cleaning. The Influence of Soot and Scale Removal on the Economy of Steam-Boiler Plants (Der Einfluss der Reinigung auf die Wirtschaftlichkeit der Dampfkesselanlage), M. Schimpf. Glückauf, vol. 57, no. 15 Apr. 9, 1921, pp. 345-346. Results of tests carried out on a double-flue boiler showing saving of 15 per cent of fuel through cleaning.

The Removal of Sludge from Steam Boilers (Das Abschlammen des Dampfkessels). Chemiker-Zeitung, vol. 45, no. 3, Jan. 6, 1921, p. 30, 1 fig. Discusses unobserved losses in steam operation and importance of sludge removal from boilers. Details and advantages of blow-off valve constructed by firm of Gustav F. Gerdts, Bremen, Germany.

Electrically Heated. Useful Possibilities of the Electric Boiler (Något om den elektriska ångpannans användningsmojligheter), Otto Stålhane. Teknisk Tidskrift, vol. 51, no. 4, Apr. 6, 1921, pp. 56-61, 8 figs. Describes boiler types and discusses three possibilities, namely (1) complete reconstruction of boiler through installation of resistances in the tubes and walling up of the smoke flues; (2) installation of boilers which can be electrically heated part of year and with coal when electric current is not constantly available; and (3) if current is constant, but not available at all times of the day, the use of a special electric boiler. Electric boilers offer possibility for complete utilization of water power.

Marine. See MARINE BOILERS.

Vertical. The Construction of Small Vertical Boilers (Ueber den Bau von kleinen stehenden Kesseln), E. Höhn. Zeit. des Bayerischen Revisions-Vereins, vol. 25, no. 10, May 31, 1921, pp. 84-86, 3 figs. Explosion occurring in Switzerland in 1915 was attributed to poor quality of welded seam between smoke tube and fire box end, and to use of bumped heads. To prevent recurrence of similar accidents regulations have been adopted by Swiss boiler manufacturers.

Water Concentration. Concentration of Water in Steam Boilers, Victor J. Azbe. Power, vol. 54, no. 2, July 12, 1921, pp. 46-48, 4 figs. Description of densimeter, an apparatus for determining water concentration by sodium chloride method.

BOILERS, WATER-TUBE

Vertical. The Piedboeuf Vertical Water-Tube Boilers (Der Biedboeuf-Steilrohrkessel), Paul Koch. Der praktische Maschinen-Konstrukteur, vol. 54, no. 11, Mar. 17, 1921, pp. 81-82, 2 figs. Vertical water-tube boilers with improved Garbe tube sheets pressed to provide flat surface for tube holes.

BORING MACHINES

Taper Head. A New Taper Head for Boring and Turning Mills. Machy. (Lond.), vol. 18, no. 455, June 16, 1921, pp. 332-333, 5 figs. Device patented by Geo. Richards & Co., Manchester, England.

BRAKES

Electric vs. Pneumatic. Experiences with Different Types of Brakes on the Berlin Street Railway (Erfahrungen mit verschiedenen Bremsarten bei der Berliner Strassenbahn), E. Kindler. Elektrische Kraftbetriebe u. Bahnen, vol. 19, no. 10, May 24, 1921, pp. 112-114, 1 fig. Experiences with pneumatic and electric brakes, from which it is concluded that the electric brake is best adapted for street-railway operation because of its simplicity and low cost of maintenance.

Train. Improvements in Train Braking. Sci. Am., vol. 124, no 26, June 25, 1921, pp. 506-507, 4 figs. Combination of straight and automatic air braking designed for control of train on steep grades.

Virginian Demonstration of Double-Capacity Brake. Ry. Mech. Engr., vol. 95, no. 7, July 1921, pp. 428-432, 8 figs. Train of 16,000 tons handled down 1.5 per cent. grade.

BRASS

Lead Determination. The Determination of Small Amounts of Lead in Brass, Francis W. Glaze. Jl. Indus. & Eng. Chemistry, vol. 13, no. 6, June 1921, pp. 553-554. Electrolytic method for determination of lead as lead dioxide.

High-Resistance. High Resistance Brass, Pendleton Powell. Brass World, vol. 17, no. 6, June 1921, pp. 151-153. Manufacture of special brasses and bronzes to resist large stresses, especially bronzes for ship propellers. Translated from Bulletin Technologique des Arts et Métiers.

BUILDING CONSTRUCTION

Cost Accounting. Construction Accounting under Uniform System. Elec. Rev. (Chicago), vol. 79, no. 1, July 2, 1921, pp. 6-9. Each item of expenditure classified and recorded in form to segregate costs on various plants and lines and on various specific parts of such plants and lines. Examples of accounts.

Construction Costs, W. N. Connor. Jl. Boston Soc. Civil Engr., vol 8, no. 5, May 1921, pp. 157-197, 12 figs. Suggested forms for keeping records of costs in building construction.

Steel-Frame. Reducing the Cost of Steel-Frame Building, R. Fleming. Jl. Western Soc. of Engrs.,

C

CABLEWAYS

Aerial. Aerial Cableways (Les transporteurs aériens a cables), F. Cretio. Génie Civil, vol. 78, no. 19, May 7, 1921, pp. 385-390, 4 figs. Study of stresses in cable and resistance of carriage to travel. Notes on design.

CAR DUMPERS

German. Devices for the Unloading of Railway Cars (Vorrichtungen zur Entleerung von Eisenbahnwagen), G. W. Koehler. Fördertechnik u. Frachtverkehr, vol. 14, nos. 10 and 11, May 13 and 27, 1921, pp. 110-112 and 124-126, 15 figs. Describes several types.

CARS

Armored Ends. Great Central Railway Vehicles with Armoured Ends, Collision Buffers and Interlocking Fenders. Ry. Gaz., vol. 34, no. 23, June 10, 1921, p. 883, 1 fig. Object of construction is to provide buffing and interlocking arrangement whereby underframes of carriages are prevented from getting out of alignment and any tendency to mounting or over-riding is prevented.

Buffer Plates. Avoiding Rupture of Buffer Plates by Proper Heating Treatment (Studio sulla fragilita e sulla rigenerazione per ricottura dei respingent ferroviari), P. Forcella. Rivista tecnica delle Ferrovie Italiane, vol. 19, no. 5, May 15, 1921, pp. 130-134, 16 figs. on 3 supp. plates. Based on photomicrographic examinations of broken surfaces.

Couplings. Impact and Its Relation to Damage Claims, J. A. Pilcher. Ry. Age, vol. 71, no. 2, July 9, 1921, pp. 77-79, 1 fig. Graph showing relation between speed at which cars are coupled and force of impact. Evils are avoided when speed does not exceed 2 miles an hour.

Dump. Large Dump Cars for Use in the Absolute-Removal System of Stripping Overburden from Coal. Coal Age, vol. 19, no. 25, June 23, 1921, pp. 1117-1118, 3 figs. Car will carry rocks up to 18 tons weight, gives 5-ft. clearance for dumping and will hold 43 cu. ft. of material and discharge running or standing and right or left.

Heavy Types. Heavy Locomotives for the Southern Pacific. Ry. Age, vol. 71, no. 1, July 2, 1921, pp. 15-17, 4 figs. Pacific and Santa Fe types. Characteristics: Pacific, tractive effort, 43,660 lb.; cylinders, 25 in. by 30 in.; weight, total engine, 297,800 lb.; wheelbase, driving, 13 ft.; Santa Fe, tractive effort, 75,150 lb.; cylinders, 29½ in. by 32 in.; weight, total engine, 385,900 lb.; wheelbase, driving, 22 ft. 10 in.

Insulation. Insulation of Freight and Passenger Cars, Wm. N. Allman. Ry. Mech. Engr., vol. 95, no. 7, July 1921, pp. 444-449, 3 figs. Theoretical and practical considerations; values of various materials; calculating heat transmission.

CARS, FREIGHT

All-Steel. New All-Steel Wagon Stock for India. Ry. Gaz., vol. 34, no. 24, June 17, 1921, pp. 930-931, 4 figs. High-capacity hopper and rail wagons constructed by Midland Ry. Carriage & Wagon Co., Birmingham, for Bengal-Nagpur Ry. Dimensions: Extreme length over buffers, 44 ft. 11 in.; length of body, 35 ft.; width over underframe solebars and inside body, 9 ft.; tare weight, 21 tons 17 cwt.

Draft-Gear Tests. Draft Gear Tests of the Railroad Administration. Ry. Mech. Engr., vol. 95, no. 7, July 1921, pp. 435-441, 6 figs. Car-impact tests at T. H. Symington Co. testing plant at Rochester, N. Y. Methods of combining and interpreting records.

Reinforced-Concrete. Reinforced-Concrete Railway Cars (Eisenbahnwagen aus Eisenbeton), A Kleinlogel. Verkehrstechnik, vol. 38, no. 4, Feb. 5, 1921, pp. 45-48, 3 figs. Economical advantages, construction and useful scop of reinforced-concrete cars.

CARS, MAIL

Unit-Container. Epoch-Making Experiments with Unit-Container Mail Cars. Transportation World, vol. 3, no. 4, June 1921, pp. 11-12, 2 figs. Removable container cars operated by New York Central.

CARS, PASSENGER

Disinfection. The Disinfection Plant of the Vienna Municipal Street Railway (Entkeimungsanlage der Wiener städtischen Strassenbahnen im Bahnhof Simmering). Zeit. des Oesterr. Ingenieur- u. Architekten-Vereines, vol. 73, no. 20-21, May 28, 1921, p. 141. Cleaning of railway cars, etc., is effected by means of formalin vapors with vacuum in boiler, with which a thorough and rapid disinfection is insured without damage to cars.

Heating. Two-Part Coupling for Car Steam Hose ("Unikum," Kupplung für zweiteilige Dampfheizschläuche), L. Peuser. Organ für die Fortschritte des Eisenbahnwesens, vol. 58, no. 8, Apr. 15, 1921, pp. 78-79, 4 figs. Couplings adopted by Czecho-Slovakian State Railway for cars of the Kaschau-Oderberg railway.

CARS, REFRIGERATOR

Inspection. Transportation Economics of the Refrigerator Car, H. R. Newlean. A.S.R.E. Jl., vol. 7, no. 5, Mar. 1921, pp. 383-389. Inspection practice of Fruit Dispatch Co., vendors for United Fruit Co.

CARBURETORS

Tests. Trials of German Carburetors for Using Non

Volatile Fuels, Benno R. Dierfeld. Automotive Industries, vol. 45, no. 1, July 7, 1921, pp. 4–5, 2 figs. Winning instruments in competitive tests made partly on road and partly on laboratory testing stand.

CAST IRON

Research. British Iron Research Association Meets, Joseph Horton. Foundry, vol. 49, no. 13, July 1, 1921, pp. 531–532. Progress made in development of British Cast Iron Research Association.

CEMENTS

Acid-Proof. Acid-Proof Cements (Säurefeste Kitte). H. Kleinlogel. Chemiker-Zeitung, vol. 45, no. 54, May 5, 1921, pp. 432–433. Satisfactory results obtained from tests with cements from firm of Rössler, Bensheim, Germany, to be used for lining reinforced-concrete containers for different kinds of acids.

CENTRAL STATIONS

Operation. Organization and Operation of Interconnected Electric Plants (L'esprit des groupements de centrales, leur organisation—Leur exploitation), Fernand Courtoy. Association des Ingénieurs électriciens sortis de l' Institut Electro-technique Montefiore, vol. 3, no. 5, 1921, pp. 99–146, 15 figs. Regulations for establishment of corporations to engage in exploitation of centralized electrical systems. Technical and financial study.

Southern U. S. The Industrial Load in the Southern States. Elec. World, vol. 77, no. 26, June 25, 1921, pp. 1473–1477, 2 figs. Industrial plants of this section of nation have adopted electric service to marked extent during past decade. Seventy-five per cent of electrical energy consumed is purchased from central-station systems.

CENTRIFUGALS

Water-Driven. Some Recent Developments in Water-Driven Centrifugals, F. J. Broadbent, Engineering, vol. 111, no. 2894, June 17, 1921, pp. 744–745, 6 figs. Pelton-wheel-driven machines with cage of 72 in. diameter.

CHEMICAL INDUSTRIES

Prohibition and. Alcohol and the Chemical Industries, J. M. Doran. Jl. Indus. & Eng. Chemistry, vol. 13, no. 6, June 1921, pp. 564–565. Plea for regulation of prohibition in such a manner as not to interfere with chemical industries.

CLUTCHES

Design. American and British Practice in Clutch Design, Herbert Chase. Automotive Industries, vol. 44, no. 24, June 16, 1921, pp. 1302–1313, 28 figs. Advantages and disadvantages of various types of clutches are discussed and merits and demerits of many design features pointed out. Notes on theory of design and tabulation of dimensions, pressures, capacity, etc. of many makes.

Practice and Theory in Clutch Design, Herbert Chase. Jl. Soc. of Automotive Engrs., vol. 9, no. 1, July 1921, pp. 39–52, 28 figs. Comparative study of American and British practices in clutch design.

Hydraulic. High-powered Hydraulic-Clutch for Diesel-Driven Tankers. Motorship, vol. 6, no. 7, July 1921, pp. 579, 1 fig. Tests by British Admiralty of Hele-Shaw device for motorships.

COAL

Boghead. Boghead Coals (Die Bogheadkohle). H. Winter. Glückauf, vol. 57, nos. 12 and 13, Mar. 19 and 26, 1921, pp. 257–261 and 285–288. Results of investigation show that the boghead mineral is a coal similar to cannel coal, but with considerably higher content of available hydrogen.

COAL BREAKERS

Hard, Low-Volatile Coal. Sizing and Preparing a Hard Low-Volatile Coal in the Broad Top Region to Compete with Anthracite, Donald J. Baker. Coal Age, vol. 19, no. 26, June 30, 1921, pp. 1151–1154, 8 figs. Breaker built to prepare five different sizes.

COAL DUST

Sampling. Coal-Dust Sampling and Methods Adopted in Practice, R. C. Smart. Iron & Coal Trades Rev., vol. 101, no. 2779, June 3, 1921, pp. 753–754, 3 figs. Regulations of British Navy. Paper read before South Wales Inst. Engrs.

COAL HANDLING

China. Coal-Handling Plant for the Han-Yeh-Ping Iron and Coal Company, China. Iron & Coal Trades Rev., vol. 102, no. 2780, June 10, 1921, pp. 779–780, 6 figs. Electrically operated plant.

German Plant. Mechanical Coal-Handling Installation for a Steam-Boiler Plant Mechanische Kohlenbeschickeinrichtung für eine Dampfkesselanlage, gebaut von W. Fredenhagen in Offenbach (Main), Ernst Blau. Fördertechnik u. Frachtverkehr, vol. 14, no. 10, May 13, 1921, pp. 108–110, 5 figs. Automatic installation constructed by W. Fredenhagen, Offenbach, Germany, consisting of an inclined elevator and two scraper conveyors.

Piers. Mechanical Trimmers Facilitate Coal Loading, P. G. Lang, Jr. Ry. Age., vol. 70, no. 25, June 24, 1921, pp. 1433–1436, 5 figs. Baltimore & Ohio installation at Curtis Bay piers, Md.

COAL POCKETS

Concrete. A Concrete Coal Bin of Unusual Design and Construction. Am. Architect, vol. 119, no. 2369, June 8, 1921, pp. 621–627, 13 figs. Coal bin of 1900-ton capacity designed for storage of pulverized coal.

COAL STORAGE

Fire Fighting. Extinguishing Fires in Coal Stores (Die Bekampfung von Kohlenlagerbränden), H. Immerschitt. Feuerungstechnik, vol. 9, no. 16, May 15, 1921, pp. 145–149. Discusses effectiveness of the three different methods of combating fires, namely, through water, through smothering, and through cooling with salt solutions.

COAL TAR

By-Products. Tetralin and Dekalin. Sci. Am. Monthly, vol. 4, no. 1, July 1921, pp. 65–66, 2 figs. Illuminant and lubricant obtained from coal tar.

COAL TIPPLES

Construction. Among Other Preparation Devices at Diamond Mines Is One for Picking Each Separately, Donald J. Baker. Coal Age, vol. 19, no. 25, June 23, 1921, pp. 1111–1116, 8 figs. Cars brought to feeder by rope are fed to dump which revolves completely over, cars being held by wheel clamps. Reciprocating screens hang from rods and do not rest on rollers.

COBALT STEEL

Analysis. The Determination of Cobalt and Nickel in Cobalt Steels, G. E. F. Lundell and J. I. Hoffman. Jl. Indus. & Eng. Chemistry, vol. 13, no. 6, June 1921, pp. 540–543. Method based on electrodeposition of cobalt and nickel in solution freed from iron, chromium, tungsten, molybdenum, vanadium and copper.

COKE

Breeze. Boiler Fuel Mixture Tests, John Blizard and James Neil. Gas Rec., vol. 19, no. 12, June 22, 1921, pp. 25–27 and 34, 3 figs. Experiments conducted at Bur. of Mines to determine steaming value of coke breeze when mixed with Pittsburgh coal and fired by hand.

Metallurgical. Notes on the Value of Metallurgical Coke, G. Deladriere. Colliery Guardian, vol. 121, no. 3154, June 10, 1921, pp. 1668–1669, 4 figs. Graphs comparing relative values of different grades of coal. Translated from Revue universelle des mines.

COKE-OVEN GAS

Benzol Content. Determination of Benzol Content in Coke-Oven Gas (Die Benzolbestimmung im Koksofengas), A. Thau. Glückauf, vol. 57, nos. 22, 23 and 24, May 28, June 4 and 11, 1921, pp. 505–511, 529–536 and 550–562, 19 figs. Discussion and comparison of various domestic and foreign processes. Account of tests for determination by physical means, and description of an indicating or recording device for photometric determination of benzol in gas.

COKE OVENS

By-Product. Adaptability in Coke Oven Practice, C. R. Meissner. Gas Age, vol. 47, no. 12, June 25, 1921, pp. 503–506, 5 figs. Among features of Hazelwood plant are concrete casings for exhausters and boosters and flushing of collecting mains with condensate.

Plants. New Coke Ovens at St. Louis, Hector Prud'homme. Gas Rec., vol. 19, no. 12, June 22, 1921, pp. 19–23, 5 figs. Eight Piette type of ovens installed at plant of Laclede Gas Light Co. for test purposes. Thirty-day test run shows splendid results.

COLD SAWS

Use in Steel Works. The Use of High-Speed Cold Saws with Toothless Blade in Steel Works and Foundries (Verwendung schnellaufender Kaltsägen mit zahnolsem Sägeblatt in Hüttenwerken und Stahlgiessereien), A. Lobeck. Werstattstechnik, vol. 15, no. 12, June 15, 1921, pp. 351–353, 12 figs. Describes new cutting method for use with steel castings of a given shape and hardness.

COMBUSTION

Air Regulation. Industrial Comburimetry (La comburimétrielle industrielle), M. André Grebel. Chateur et Industrie, vol. 2, no. 13, May 1921, pp. 272–276, 3 figs. Apparatus for regulating amount of air necessary for combustion. (Concluded.)

Flue-Gas Analysis. Determination of Excess Air from Flue-Gas Analysis, R. Brown. Combustion, vol. 4, no. 6, June 1921, pp. 24–25, 1 fig. Construction of excess air chart.

Surface. Introduction of Surface Combustion in the German Industry (Zur Einführung der "flammenlosen Oberflächenverbrennung" in die deutsche Industrie), Rudolf Schnabel. Chemiker-Zeitung, vol. 45, no. 57, May 12, 1921, p. 457. Refers to organization of German Society for Surface Combustion possessing the rights of American, English and German patents.

COMPRESSED AIR

Waste. Saving Fuel by Decreasing Air Waste, N. A. Craigue. Indus. Management, vol. 61, no. 11, June 1, 1921, pp. 418–421, 3 figs. Methods of reducing waste and diminishing leaks in compressed air systems.

CONCRETE

Alkali Action. Progress in Investigation of Alkali Action on Concrete, E. C. Bebb. Concrete Products, vol. 20, no. 6, June 1921, pp. 27–29. Investigations conducted by Bur. of Standards, Reclamation Service, Drainage Investigations Office of Dept. of Agriculture and Portland Cement Assn.

Oven Drying. Effects on Concrete of Immersion in Boiling Water and Oven Drying, W. J. Schlick. Iowa State College of Agriculture & Mechanic Arts Official Publication, vol. 19, no. 44, Mar. 30, 1921, 24 pp., 13 figs. Experiments. Boiling without previous drying caused reduction in weight, while boiling following oven drying caused increase in weight, there having been marked loss in strength in each case.

Tests. Formula for Determining the Strength of Cement Concrete (Om en Fremgangsmaade til Bedömmelse af Mörtelmaterialers Egenskaber). Ingeniören, vol. 30, no. 18, Mar. 2, 1921, p. 133. Method used by Peter Lind & Co., Westminster, to test probable strength of concrete used for concrete ships during war.

Waterproofing. Some Methods of Securing Impermeability in Concrete, Ewart S. Andrews. Concrete & Constructional Eng., vol. 16, no. 6, June 1921, pp. 369–374. Classification of methods for securing impermeability. Paper read before Concrete Inst.

Waterproofing Concrete—I, J. H. Burgess. Commonwealth Engr., vol. 8, no. 8, Mar. 1, 1921, pp. 248–250. Permeability tests.

CONCRETE CONSTRUCTION

Gravity Plants. Graphic Wattmeter Checks Gravity Plant Operation. Eng. News-Rec., vol. 86, no. 25, June 23, 1921, pp. 1067–1068, 3 figs. Details of distant operations indicated on chart at construction engineers' desk.

CONCRETE CONSTRUCTION, REINFORCED

Developments. Modern Reinforced Concrete Industrial Structures (Moderne strutture industriali in cemento armato), Luigi Santarella. Industria, vol. 35, no. 8, April 30, 1921, pp. 175–179 and 180–181, 16 figs. Typical factory constructions.

CONDENSERS, STEAM

Cleaning. Removing Scale from Surface Condenser Tubes with Hydrochloric Acid, Norman G. Hardy. Power, vol. 51, no. 1, July 5, 1921, pp. 22–24, 1 fig. Apparatus and process described.

Acid Cleaning of Condensers, Norman G. Hardy. Elec. World, vol. 78, no. 2, July 9, 1921, pp. 64, 1 fig.

Developments. Recent Improvements in the Design of Condensers for Steam Engines (Recents perfectionnements des appareils de condensation des machines à vapeur d'eau), L. Jauch. Chaleur et Industrie, vol. 2, no. 13, May 1921, pp. 239–246, 3 figs. Technical study and historical survey. (To be continued.)

Water Screens. Largest Traveling Screens Installed at Cincinnati. Power, vol. 54, no. 2, July 12, 1921, pp. 62–64, 3 figs. Screening capacity is 200,000 gal. per min.

CONNECTING RODS

Machining Methods. Another Method of Machining Connecting Rods, Fred H. Colvin. Am. Mach., vol. 54, no. 25, June 23, 1921, pp. 1068–1069, 5 figs. Methods and fixtures. Facing both ends of boss at once. Drilling machine with special attachment. Boring two rods in one operation.

Machining Connecting Rods. Eng. Production, vol. 2, no. 38, June 23, 1921, pp. 744–746, 11 figs. Methods employed at leading automobile factories.

CONVEYORS

Workshop. Mechanical Conveyors for Workshops, Hubert Hermanns. Forging & Heat Treating, vol. 7, no. 6, June 1921, pp. 316–319, 10 figs. Types used in German workshops.

COPPER

Gases, Action on. The Action of Reducing Gases on Heated Copper, H. Moore and S. Beckinsale. Engineering, vol. 111, no. 2893, June 10, 1921, pp. 729–732, 8 figs. Results obtained in experiments showed that injurious effect of reducing gases on heated copper is result of their interaction with cuprous oxide always present in commercial copper. Markedly injurious effect is produced even when oxygen content of copper does not exceed 0.026 per cent. Paper read before Inst. of Metals.

COPPER ALLOYS

Copper-Tin. The Constitution of the Alloys of Copper with Tin—III and IV, John L. Haughton. Engineering, vol. 111, no. 2895, June 24, 1921, pp. 789–793, 23 figs. Transformations occurring below eutectic temperature. Photomicrographs.

Cupro-Vanadium. Non-Ferrous Applications of Vanadium, Kirby Thomas. Raw Material, vol. 4, no. 5, May 1921, pp. 167–168. Cupro-vanadium being used in brasses and bronzes.

CORROSION

Concrete Reinforcement. Reinforcing Steel in Cements Containing Blast-Furnace Slag (Eiseneiolagen in hochofenschlackenhaltigen Zementen), Richard Grün. Stahl u. Eisen, vol. 41, no. 17, Apr. 28, 1921, pp. 577–579. Laboratory tests show that an injurious rusting of iron in alkaline cement masses is impossible providing construction is sufficiently airtight. Practical experience shows that in properly prepared reinforced concrete of blast-furnace cement or of portland cement, the core iron remains permanently unchanged.

Protective Treatments. Notes on Oxydizing Cementation, Galvanization, Sherardizing and Metalizing Spraying (La cémentation oxydante. La galvanisation. La shérardisation. La métallisation par pulvérisation), J. Arnoul de Grey. Chaleur et Industrie, vol. 2, no. 13, May 1921, pp. 255–262. Exposition and comparative study of methods of protecting metallic objects against corrosion. (To be continued.)

Steam Pipes. A Case of Rust Formation (Ein Fall von Rostbildung), E. Sauer. Chemiker-Zeitung vol. 45, no. 53, May 3, 1921, p. 421. Describes case of corrosion of a steam pipe caused by carbonic-acid content of the steam, demonstrating importance of removal of gases, especially of carbon dioxide from feedwater.

COST ACCOUNTING

Overhead Costs. Budgeting Factory Overhead,

pp. 31–34, 4 figs. Experience in operation of budget plans of Fairbanks, Morse & Co. and of A. O. Smith Corp.

Uniform System. Advises Use of Uniform Cost System, Robert E. Belt. Foundry, vol. 49, no. 13, July 1, 1921, pp. 524–526. Economical advantages of introducing uniform cost system in manufacturing plants. Paper read before National Industrial Cost Conference.

COUPLINGS

Whitney Free Floating. Whitney Free Floating Coupling. Power, vol. 54, no. 1, July 5, 1921, pp. 24, 2 figs. Designed to allow for misalignments, either parallel or angular. Coupling consists of two hubs and special design of driving link.

CRANES

Tower. Tower Crane for Handling Timber. Engr., vol. 131, no. 3415, June 10, 1921, pp. 624–625, 1 fig. Designed to deal with loads of 5 tons at radius of 50 ft. and of 3 tons at radius of 100 ft.; with clear height of lift of 52 ft.

CRANKCASES

Machining Operations. Details of Crankcase Work. Am. Mach., vol. 54, no. 25, June 23, 1921, pp. 1088–1090, 9 figs. Different types of reaming fixtures. "Hand" reaming by pneumatic motor. Running in crankshaft bearings by power. Roller conveyors as labor savers.

CUPOLAS

Clays for Daubing. Cupola Daubing Clay Affects Iron, Carl Buberl. Foundry, vol. 49, no. 13, July 1, 1921, pp. 533–534. Poor and good clays for daubing cupola are defined and results of tests showing detrimental effects of poor grade of refractory given. Aluminum additions improve quality.

Oil Firing. Oil Lowers Cost of Fuel in Cupola, Karl K. Berthold. Foundry, vol. 49, no. 13, July 1, 1921, pp. 530–531. Experience at Austrian Foundry. Oil was introduced as adjunct to coke in cupola and cost of fuel was decreased in consequence as well as metal with lower sulphur content was obtained. Translated from Stahl u. Eisen.

Operation. Fitting the Cupola to Its Work, Y. A. Dyer. Iron Age, vol. 107, no. 25, June 23, 1921, pp. 1675 and 1727–1729. Cupola operation. Physical and chemical factors as related to efficiency. Position of fusion zone.

CUTTING TOOLS

Design. Metal Cutting Tools—XII, A. L. DeLeeuw. Am. Mach., vol. 55, no. 1, July 7, 1921, pp. 4–9, 13 figs. Form tools; plate tools, bar tools and circular form tools. Advantages and disadvantages of each. Shaving tools and their action.

D

DIE CASTING

Developments. Latest Developments in the Die-Casting Industry. Raw Material, vol. 4, no. 5, May 1921, pp. 156–163, 13 figs.

DIESEL ENGINES

North British. The North British Diesel-Engine, Motorship, vol. 6, no. 7, July 1921, pp. 568–569. 4 figs. Four-cycle, single-acting, crosshead type developing 2300 hp.

Solid-Injection. Injection and Combustion of Fuel-Oil—IV, C. J. Hawkes. Motorship, vol. 6, no. 7, July 1921, pp. 573–574, 1 fig. Experiments with solid injection and air blast in marine Diesel-engines. (Continuation of serial.)

Standardized. Standardized Diesel Engines—V, H. R. Setz. Mar. Eng., vol. 26, no. 7, July 1921, pp. 548–552, 7 figs. Discussion of double-acting two-cycle engine and its possibilities.

DRAWINGS

Filing. Systems for Indexing and Filing Drawings. Eng. & Contracting, vol. 55, no. 25, June 22, 1921, pp. 609–611, 4 figs. Systems used by five prominent engineering and manufacturing enterprises. Paper read before Cleveland Eng. Soc.

DRILLING MACHINES

High-Power. High-Power Drilling Machines with Central Drive (Hochleistungs-Bohrmaschine mit Zentralantrieb), P. Castenholz. Der praktische Maschinen-Konstrukteur, vol. 54, no. 12, Mar. 24, 1921, pp. 49–51, 5 figs. Machine constructed by Gebhard Bischof Machine Works, Reutlingen, Germany, for single-pulley drive through vertical shaft in column.

Manufacture. Building Drilling Machines. Eng. Production, vol. 2, no. 36, June 9, 1921, pp. 694–703, 24 figs. Methods at works of Associated British Machine Tool Makers, Halifax.

Multiple-Spindle. Drilling Two Different Parts on One Machine, J. H. Moore. Can. Machy., vol. 25, no. 25, June 23, 1921, pp. 25–27, 9 figs. Uses and advantages of multiple-spindle drilling machines. Typical examples of work.

Heavy Multiple-Head Drilling Machines. Engineering, vol. 111, no. 2893, June 10, 1921, pp. 714 and 716, 2 figs. Designed by Beyer, Peacock & Co., Manchester, England, to meet requirements of locomotive and marine engine shops.

DROP FORGING

Ingots for. Billets for the Drop Forger, Harry Brearley. Forging & Heat Treating, vol. 7, no. 6, June 1921, pp. 307–313, 13 figs. Cracks, blowholes, pipe and segregates in ingots, and laps, roaks, burning discussed.

Plants. Drop-Forge Plant Lay-Out and Equipment. Machy. (N. Y.), vol. 27, no. 11, July 1921, pp. 1039–1044, 9 figs. Drop-forging plant arranged for handling large quantities of work.

DUST

Measurement of Dustiness. The Shinizu-Wilson Cloud-Condensation Apparatus. Elecn., vol. 86, no. 2247, June 10, 1921, pp. 720, 2 figs. Apparatus for measuring dustiness of atmosphere. Modifications of Wilson cloud-condensation apparatus.

E

EDUCATION, ENGINEERING

Problem of. How Should the Engineer Be Educated? F. L. Bishop, Knox Taylor, Comfort A. Adams, W. C. Spruance, Moorhead C. Kennedy, R. E. Anderson and Donald A. Hampson. Am. Mach., vol. 54, no. 26, June 30, 1921, pp. 1105–1109. Résumé of remarks expressed at joint meeting of Am. Soc. of Mech. Engrs. and Am. Inst. of Elec. Engrs.

United States. Engineering College Registration Shows 4-Per cent Gain. Eng. News-Rec., vol. 86, no. 26, June 30, 1921, pp. 1104–1106, 3 figs. Census by Eng. News-Rec. covered 48,312 students in 81 institutions located in 36 states. Mechanical engineering was most popular course.

ELASTICITY

Moduli. Elasticity. Engineering, vol. 111, no. 2893, June 10, 1921, pp. 701–702, 13 figs. Derivation of formula expressing relation between moduli of elasticity.

ELECTRIC DRIVE

Cement Industry. Electrified Cement Industry Aids Western Construction, Lloyd W. Chapman. Jl. Electricity & Western Industry, vol. 47, no. 1, July 1, 1921, pp. 7–10, 5 figs. Methods of manufacturing portland cement at Santa Cruz Portland Cement Co.

Logging Industry. Electric Applications in the Logging Industry of the Northwest, E. P. Whitney. Gen. Elec. Rev., vol. 24, no. 7, July 1921, pp. 631–638, 8 figs.

Pumps. Electric-Motor Drives for Pumps, Gordon Fox. Power, vol. 54, no. 1, July 5, 1921, pp. 2–5, 5 figs. Advantages of reciprocating and centrifugal pumps. How to figure capacities and power required. Operating characteristics. Types of motor to use for different kinds of service.

Textile Industry. Selection of Polyphase Motors, Benjamin F. Bailey. Elec. World, vol. 78, no. 1, July 2, 1921, pp. 16–19, 7 figs. Electric drive in textile industry. Comparison of electrical and physical characteristics that affect service requirements. Choice of speed, frequency weight and rating are considered. Squirrel-cage compared with wound-rotor motor.

ELECTRIC FURNACES

Arc. A New Indirect Arc Furnace. Metal Industry (Lond.), vol. 18, no. 23, June 10, 1921, pp. 442–443, 2 figs. Three-phase gyrating furnace manufactured by Volta Mfg. Co., Welland, Ont.

Inductive. Recent Progress in High-Frequency Inductive Heating, E. F. Northrup. Chem. & Metallurgical Eng., vol 24, no. 25, June 22, 1921, pp. 1097–1100, 5 figs. Notes on design, operation, melting rate and power input of electric furnaces using high-frequency inductive heating. Electric furnaces are being used for melting precious metals at U. S. Mint and by leading silver broker. Paper read before Am. Electrochemical Soc.

Laboratory. Electric Muffle Furnaces for Laboratory Use, H. C. Kremers. Jl. Indus. & Eng. Chemistry, vol. 13, no. 6, June 1921, pp. 561, 2 figs. Muffle made up of nickel-chromium alloy wire wound around glass cylinder covered with asbestos.

Tagliaferri. Tagliaferri Electric Furnace (Le four electrique "Tagliaferri"), Mario-Marantonio. Journal du Four Electrique, vol. 30, no. 7, May 1 & 15, 1921, pp. 53–58, 9 figs. Operation and heat distribution are regulated by auxiliary electrodes. Patented by Société anonyme de Fours électriques.

ELECTRIC PLANTS

Interconnection. Power Administration Effects Economy, Fred B. Lewis. Elec. World, vol. 78, no. 2, July 9, 1921, pp. 57–58, 4 figs. Methods which have been adopted in California to operate steam and hydroelectric plants for maximum efficiency and economy of resources.

ELECTRIC WELDING, ARC

Castings. Application of Arc Welding in Machinery Construction, A. M. Candy. Elec. Rev. (Chicago), vol. 79, no. 1, July 2, 1921, pp. 1–5, 7 figs. Heavy castings damaged in shop or in operation repaired with speed by welding process. Forging weld increased its strength and quality. Paper before Soc. of Refrigerating Engrs.

Railway Shops. Electric Arc Welding in Railroad Shops, A. M. Candy. Ry. Mech. Engr., vol. 95, no. 7, July 1921, pp. 456–458, 7 figs. Explanation of the characteristics of arc-deposited metal and some samples of welding.

ELECTRICAL INDUSTRY

Developments. Personal Observations in the Industry, Arthur W. Berresford. Jl. Am. Inst. Elec. Engrs., vol. 40, no. 7, July 1921, pp. 555–560. Suggestions in regard to furthering industrial progress.

Industrial. The Use of Electricity in Special Industries in the West. Jl. Electricity & Western Industry, vol. 46, no. 12, June 15, 1921, pp. 612–624, 34 figs. Eighty-six per cent of energy sold by western power companies goes to industrial consumers. Survey of conditions.

ELEVATORS

Freight, Safeguarding. Freight Elevators. Power Plant Eng., vol. 25, no. 13, July 1, 1921, pp. 667–669, 3 figs. Safeguarding shaftways, cables, counterweights and operation. Prepared by eng. staff of Nat. Safety Council.

Governors. Electric Elevator Machinery, Overspeed Governors, M. A. Myers. Power, vol. 54, no. 2, July 12, 1921, pp. 50–51, 13 figs. Types of safety governors.

EMPLOYMENT MANAGEMENT

Testing Employees. Industrial Psychotechnology (Industrielle Pyschotechnik), A. Wallichs. Zeit. des Vereines deutscher Ingenieure, vol. 65, no. 25, June 18, 1921, pp. 648–651. Development of adaptability tests; related methods and their utilization. Discussion of results already obtained and prospects of future development.

ENAMELING

Steel. The Vitreous Enamelling of Steel and Iron, Charles M. Bowes. Metal Industry (Lond.), vol. 18, no. 23, June 10, 1921, pp. 441–442. Outline of processes.

ENGINEERS

Licensing. Ethical and Practical Considerations Regarding the Engineering Corporation. Eng. News-Rec., vol. 86, no. 26, June 30, 1921, pp. 1109–1111. Holds that ethical questions are not essentially different from those confronting individual consultants.

EXHAUST STEAM

Utilization. Generating Power with Exhaust from Mill Engines. Power Plant Eng., vol. 25, no. 13, July 1, 1921, pp. 641–646, 10 figs. Mixed-pressure turbines and regenerators installed at plant of National Enameling & Stamping Co.

EXPLOSIVES

Liquid Oxygen. The Potentialities of Liquid Oxygen Explosives, Robert G. Skerrett. Compressed Air Mag., vol. 26, no. 6, June 1921, pp. 10103–10107, 7 figs. Use of liquid oxygen in German mines.

F

FACTORIES

Reinforced Concrete. A Modern Multi-Storied Shop for Building Machine Tools, Fred H. Colvin. Am. Mach., vol. 54, no. 26, June 30, 1921, pp. 1114–1118, 11 figs. Five-story building of reinforced concrete. Notes on lighting, heating and ventilating systems, also on method of handling chips.

FACTORY MANAGEMENT

See INDUSTRIAL MANAGEMENT.

FIRE PREVENTION

Exposed Woodwork. Ignitions of Combustible Materials, Especially Exposed Woodwork, by Heat-Producing Apparatus, C. E. Worthington. Safety Eng., vol. 41, no. 6, June 1921, pp. 256–263, 2 figs. Protecting devices, notably for metal smokestacks and insulation for smoke pipe.

FIRECLAYS

Thermal Expansion. The Reversible Thermal Expansion of Fireclay and Other Refractory Materials, H. S. Houldsworth and John W. Cobb. Jl. Soc. Glass Technology, vol. 5, no. 17, May 1921, pp. 16–38 and (discussion) pp. 38–44, 12 figs. Reversible thermal expansion up to 100 deg. cent. were determined for fireclay, fireclay mixtures, ganister, alumina magnesia and carborundum.

FLUE-GAS ANALYSIS

Determination of Sulphur Dioxide and Trioxide. The Determination of Sulphur Dioxide and Sulphur Trioxide in Flue Gas and Fuming Sulphuric Acid (Ueber die Bestimmung von Schwefeldioxyd neben Schwefeltroxyd in Röstgasen und Oleum), A. Sander. Chemiker-Zeitung, vol. 45, no. 33, Mar. 17, 1921, pp. 261–263, 1 fig. Method developed by author for determination of sulphur dioxide alongside of sulphur trioxide with use of only one apparatus and a single titration liquid, based on influence of mercuric chloride on sodium bisulphide.

FOREMEN

Training. Practical Methods of Training Foremen, S. Gordon Taylor. Indus. Management, vol. 62, no. 1, July 1, 1921, pp. 23–26. Experience in organization of welfare work in shipyard.

FORGING PLANTS

Layout. Building a Forge Shop for Custom Work, E. L. Shaner. Iron Trade Rev., vol. 68, no. 26, June 30, 1921, pp. 1786–1790, 7 figs. Layout of forge plant producing miscellaneous steel drop forges and forges for railroad car equipment, oil-and-gas well supply manufacturers, etc.

FORGINGS

Metal Involved. Chart for Determining Metal Involved in Forgings, H. Kilborn. Forging & Heat Treating, vol. 7, no. 6, June 1921, pp. 314–315, 1 fig.

FRAMES

Reinforced-Concrete. Axial versus Center Moment in the Calculation of Reinforced-Concrete

Frames (Ein Beitrag zur der Frage: Achsen-oder Mittelmoment bei der Berechnung von Eisenbetonrahmen), Horst Wolf. Bauingenieur, vol. 2, no. 11, June 15, 1921, pp. 304–306, 2 figs. Points out that in calculation of a frame the most accurate results can in all cases be obtained when center line is assumed to be axis of frame.

FREIGHT HANDLING

German vs. American Practice. Railway Freight Traffic (Leistungen im Eisenbahn-Güterverkehr), H. Wernekke. Fördertechnik u. Frachtverkehr, vol. 14, no. 10, May 13, 1921, pp. 107–108. Figures showing efficiency of German and American railways in freight-train traffic, from which it is concluded that while American railways show heavier traffic, German railways show a much more thorough and efficient utilization of rolling stock.

FUELS

Heat Value. Calculation of Heat Value from the Constitution of Compound (Studien über die Berechnung des Heizwertes aus der Konstitution der Verbindung), F. Otto H. Binder. Chemiker-Zeitung, vol. 45, no. 18, Feb. 10, 1921, p. 141. Discussion based on the Dulong formula for calculation of theoretical heat value of a fuel from its elementary composition.

[See also OIL FUEL; PULVERIZED COAL.]

FURNACES

Recuperator. An Automatic Recuperator Furnace. Machy. (Lond.), vol. 18, no. 454, June 9, 1921, pp. 303, 2 figs. Gas furnace designed for utilizing waste flue gases as aid to combustion.

FURNACES, ANNEALING

Oil-Fuel-Burning. Anneals Malleable with Fuel Oil, William F. Hoernke. Iron Trade Rev., vol. 68, no. 25, June 23, 1921, pp. 1728–1730, 4 figs. Conversion of coal burning annealing ovens into oil burning ovens. Operation shows that although oil is more expensive fuel, it requires less labor in handling and firing.

FURNACES, BOILER

Insulation. Boiler Furnace Insulation, Frank W. Sterling. Jl. Am. Soc. of Naval Engrs., vol. 33, no. 2, May 1921, pp. 268–284, 10 figs. Methods of testing furnace insulation.

Lignite-Burning. New Lignite Furnaces (Neue Feuerungen für Rohbraunkohle). Der prakitsche Maschinen-Konstrukteur, vol. 54, no. 12, Mar. 24, 1921, pp. 89–90. Adjustable semi-producer-type step grate constructed by Jacques Piedboeuf, Ltd., Düsseldorf, which is said to insure proper distribution and regulation of air required for combustion and for obtaining maximum gas temperatures in furnaces, easy manipulation and cleaning facilities, especially with regard to removal of ashes and slag.

The Adaptation of Furnace Installations to Use of Lignite (Wie stelle ich am besten meine Feuerungsanlage auf Rohbraunkohlen um?), O. Binder and R. Scharf. Chemiker-Zeitung, vol. 45, no. 30, Mar. 10, 1921, pp. 237–239. Recommends installation of economically operated stepped-grate furnace.

Turbine. Cochran Boiler Fitted with the Turbine Furnace. Iron & Coal Trades Rev., vol. 103, no. 2780, June 10, 1921, p. 788, 2 figs. Tests on turbine patented furnace built by Turbine Furnace Co., London.

FURNACES, HEATING

Automatic Firing. Air Furnace Is Fired Automatically. Foundry, vol. 49, no. 13, July 1, 1921, pp. 515–517, 4 figs. Coal dumped into hopper which feeds specially designed grate as coal burns. Only manual labor necessary is that required for pulling ashes.

Continuous. Heating Furnaces and Annealing Furnaces, W. Trinks. Forging & Heat Treating, vol. 7, no. 6, June 1921, pp. 320–324, 6 figs. Comparison of different types of continuous furnaces. Test results.

FURNACES, HEAT-TREATING

Gas. The Value of Gas for Heat Treating, F. F. Cauley. Forging & Heat Treating, vol. 7, no. 6, June 1921, pp. 328–331, 8 figs. Typical modern installations.

FURNACES, HOT-AIR

Research. Investigation of Warm-Air Furnaces and Heating Systems, A. C. Willard, A. P. Kratz, and V. S. Day. University of Ill. Bul., vol. 18, no. 29, Mar. 21, 1921, 145 pp., 49 figs. Determination of efficiency and capacity of commercial warm-air furnaces under conditions similar to those existing in actual installations with leaders, stacks, and registers, to form complete system; study rating furnaces and investigations of value of insulating materials as affecting economy of furnace.

G

GAGES

Industrial. Study of Industrial Gages at International Bureau of Waste and Measures (L'étude des calibres industriels au bureau international des poids et mesures), Albert Pérard. Genie Civil, vol. 78, no. 23, June 4, 1921, pp. 477–480, 11 figs. Types of gages employed. (To be continued.)

Inspection. The Delco Inspection System, Erik Oberg. Machy. (N. Y.), vol. 27, no. 11, July 1921, pp. 1032–1034 8 figs. Description of methods used in tool and gage designing dept. of Dayton Eng. Laboratories Co., and standards of gaging adopted.

Lever. The Accuracy of Multiple Lever Gages (Die Genauigkeit mehrfacher Fühlhebel), G. Berndt. Werkstattstechnik, vol. 15, no. 12, June 15, 1921, pp. 347–350, 2 figs. Comparison of accuracy of single and multiple levers. States that, when possible, instead of using several levers with smaller gear ratios, it is better to use a double or single lever with gear ten times as great.

GAS MANUFACTURE

Producer Process, Loss in. Thermal Losses in the Gas Producer Process, N. E. Rambush. Jl. Soc. Chem. Industry, vol. 40, no. 12, June 30, 1921, pp. 129T–137T, 5 figs. Principles by means of which it is possible to determine thermal efficiency of gasification of a given fuel without large-scale tests.

GAS MASKS

Charcoal. The Occlusion of Water by Gas-Mask Charcoal, Ben E. Brown. Physical Rev., vol. 17, no. 6, June 1921, pp. 700–706, 2 figs. Variation of amount of water with temperature was determined between 102 and 140 deg. cent. at pressure of 74 cm. of mercury. About ⅓ of water came off between 112 and 114 deg. cent.

GAS TURBINES

Combustion Chambers. Gas-Turbine Combustion Chambers, Glenn B. Warren. Power, vol. 53, no. 26, June 28, 1921, pp. 1059–1060, 2 figs. Experiments at University of Wisconsin on four types of combustion chambers.

GEAR CUTTING

Bevel-Gear Planer. Gleason 37-In. Two-Tool Bevel-Gear Planer. Am. Mach., vol 54, no. 26, June 30, 1921, pp. 1123–1125, 5 figs. Automatic machines intended for general work. Tools cut on opposite sides of tooth.

Continuous Machines. Generating Gear Teeth for Industrial Uses, J. H. Moore. Can. Machy., vol. 25, no. 23, June 9, 1921, pp. 25–27, 8 figs. Continuous type of gear-cutting machines.

Helical Gears. Cutting Large Double Helical Gears, C. S. Pettit. Machy. (Lond.), vol. 18, no. 454, June 9, 1921, pp. 308–309, 4 figs. Machines developing continuous teeth by means of rack cutter using reciprocating motion.

GEARS

Bevel. The Spiral Bevel Gear. Machy. (Lond.), vol. 18, no. 456, June 23, 1921, pp. 352–354, 3 figs. Matterson type of spiral bevel gear. Criticism of article in Machy. (Lond.), May 12, p. 174.

Design. Calculation of Special Gears, Speeds of Which Are in Geometrical Progression (Berechnung besonderer Getriebe, deren Umläufe nach einer geometrischen Reihe abjestuft sind), H. Vorwerck. Der praktische Maschinen-Konstrukteur, vol. 54, no. 10, Mar. 10, 1921, pp. 42–44, 5 figs. Method of calculation.

Frictional. Frictional Gearing (Friktionsvorgelege). Der praktische Maschinen-Konstrukteur, vol. 54, no. 22, June 2, 1921, pp. 95–96, 6 figs. Variable-speed gear constructed by Ferdinand Wiss, Valendar, Germany, for transmission of small amounts of power.

Inspection. A New System of Gear Grinding and Gear Inspection, P. M. Heldt. Automotive Industries, vol. 44, no. 26, June 30, 1921, pp. 1430–1431, 4 figs. Great accuracy of tooth and more rolling with less sliding action are claimed. Grinding machine works on generating principle and means for compensating for wear of grinding wheel are provided.

Involute. The Evolution of the Involute Gear Tooth—VI, A. Fisher. Machy. (Lond.), vol. 18. no. 456, June 23, 1921, pp. 363–366, 7 figs. Influence of pressure angle on strength of teeth.

Maag. The Maag Gears and Their Use in Street-Railway Operation (Maagzahnräder und ihre Verwendung in Strassenbahnbetriebe), Rudolf Wahn. Elektrotechnik u. Maschinenbau, vol. 39, no. 22, May 29, 1921, pp. 267–269, 6 figs. Describes Maag method of making gears and advantages of this type which is now in use on 65 street-railway lines in Switzerland. Paper read before Int. Street and Narrow-Gage Ry. Congress, Vienna.

Non-Metallic. Design and Manufacture of Non-Metallic Gears, Fred R. Daniels. Machy. (N. Y.), vol. 27, no. 11, July 1921, pp. 1005–1011. Characteristics of gears made from rawhide and fabric-base materials. Methods employed by Van Dorn & Dutton Co., Cleveland, O., in manufacture of nonmetallic gears.

Skew. Skew Gear Design, F. E. Lindsay. Engineer, vol. 131, no. 3416, June 17, 1921, pp. 652, 5 figs. Graphical method.

Spur. Spur Gear Erosion, F. W. Lanchester, Engineering, vol. 111, no. 2894, June 17, 1921, pp. 733–734, 7 figs. Limitations to conditions under which it is desirable to use rolling rather than sliding contact. Difficulties which are liable to be associated with rolling conditions.

Testing Teeth. The Odontometer for Testing Gear Teeth, Earle Buckingham. Machy. (N. Y.), vol. 27, no. 11, July 1921, pp. 1029–1031, 6 figs. Apparatus consists of section of straight-sided rack with two parallel effective faces, one being fixed and other movable. Third face, set at angle to two working faces, is used to hold fixed working face in contact with flank of gear tooth.

GRINDING MACHINES

Continuous. The Churchill Continuous Rod Grinding Machine. Machy. (Lond.), vol. 18, no. 455, June 16, 1921, pp. 335–336, 3 figs. Machine manufacture by Churchill Machine Tool Co., Manchester, England.

H

HANDLING MATERIALS

Liquids. Handling and Measurement of Liquids in Factories (Bewegung und Messung von Flüssigkeiten innerhalb der Fabrik), H. Rahe. Chemiker-Zeitung, vol. 45, nos. 21 and 21, Feb. 17 and 24, 1921, pp. 165–169 and 191–193, 16 figs. Devices for handling, that is, conduction and measurement of liquids, such as acids, alkalies, salt solutions, hydrocarbons, and a large number of organic and inorganic liquids, such as chlorine and other liquefied gases, alcohol and ether.

Small Plants. Purchasing and Handling Material in the Small Plant—II and III, Guy V. Sweet. Indus. Management, vol. 61, no. 11, and vol. 62, no. 1, June 1 and July 1, 1921, pp. 399–402. 6 figs., and 18–21, 7 figs. June 1: Forms for keeping records and making requisitions. July 1, Forms of material record cards.

HEAT TRANSMISSION

Building Walls. The Calculation of Heat Transmission Coefficients (Ueber die Berechnung von Wärmedurchgangszahlen), Réti Mór. Gesundheits-Ingenieur, vol. 44, no. 22, May 28, 1921, pp. 262–263, 2 figs. Points to difficulties and lack of satisfactory calculating method. In supplementary article by Karl Hencky (pp. 263–264, 1 fig.) writer explains system of coefficients developed by him.

HEATING

Industrial, Local. Industrial Applications of Local Heating with the Pyrotip, E. A. Wagner. Gen. Elec. Rev., vol. 24, no. 7, July 1921, pp. 628–631, 10 figs. Heat is generated at tip of carbon rod and is transmitted by conduction to material; it is produced by resistance of carbon tip to passage of electric current.

HEATING AND VENTILATION

Humidifying Apparatus. Humidifying Apparatus for Textile Factories. Engineer, vol. 131, no. 3416, June 17, 1921, pp. 648, 3 figs. Cleworth-Wheal air-humidifying apparatus.

HEATING, ELECTRIC

Ovens and Hot Plates. Some Thermal Characteristics of Electric Ovens and Hot-Plates, Ezer Griffiths, and F. H. Schofield. Jl. Instn. Elec. Engrs., vol. 59, no. 300, April 1921, pp. 361–372, 14 figs. Specifications for conducting tests on cooking ovens.

HELICOPTERS

Design. Helicopters and Aeroplane-Helicopters (Hélicoptères et avionshélicoptères), M. Lamé. Aéronautique, vol. 3, nos. 19–20, Jan. 1921, pp. 277–281, 5 figs. Aerodynamic study of helicopter, especially of support without speed, stability and propulsion.

Oemichen. The Oemichen Helicopter (L'hélicoptère Oemichen). Aéronautique, vol. 3, no. 24, May 1921, pp. 213–214, 2 figs. Ascensional force is derived from small balloon and two horizontal propellers rotating in opposite directions.

HOISTS

Electric. Susquehanna Installs Electric Slope Hoist and at a Shaft Replaces Steam by Electric Drive. Lewis W. LeGrand. Coal Age, vol. 19, no. 21, May 26, 1921, pp. 941–944, 6 figs. To serve two radically different degrees of slope a "two-speed" hoist was installed. At shaft steam hoist was altered to electric drive by adding motor, gears and coupling.

HOUSES, CONCRETE

Construction Methods. New and Successful Method of Constructing Concrete Houses, D. V. Weed, Jr. Concrete Products, vol. 20, no. 6, June 1921, pp. 13–15, 4 figs. Lamouldette system employing interchangeable light steel forms or units, specially rolled and shaped for maximum strength which may be set up to either vertical or horizontal position and quickly clipped together by ingenious device to form rigid mold into which concrete is poured and structure cast as monolith.

Design. A Concrete House Scheme. Concrete & Constructional Eng., vol. 16, no. 6, June 1921, pp. 353–359, 7 figs. Typical English design.

HOUSING

Industrial. The Calder Report on the Building Situation. U. S. Dept. of Labor, Monthly Labor Rev., vol. 12, no. 6, June 1921, pp. 96–100. Report to U. S. Senate of Select Committee on Reconstruction and Production. Among recommendations is creation of "a bill to establish in Dept. of Commerce a division for the gathering and dissemination if information as to the best construction practices and methods, technical and cost data, and matters relating to city planning, etc., in order to encourage standardization and improved building practices throughout the country."

HYDRAULIC MACHINERY

Manufacture. Building Hydraulic Machinery. Eng. Production, vol. 2, no. 38, June 23, 1921, pp. 749–754, 15 figs. Procedure at representative works.

HYDRAULIC TURBINES

Francis Type. Kern River Three Development has Highest Head Francis Turbines Installed. Power, vol. 53, no. 25, June 21, 1921, pp. 996–999, 5 figs. Two vertical-shaft 22,500-hp. Francis-type turbines operating under effective head of 800 ft. Two runners are provided for each unit, one for 50-cycle and one for 60-cycle operation. Water is carried through series of tunnels aggregating 60,000 ft. in length, longest single bore being 7,132 ft.

HYDROELECTRIC PLANTS

France. Hydroelectric Installation on the Arly

River (Installation hydro-électrique de l'Arly), Francis Babey. Électricien, vol. 37, no. 1274, April 15, 1921, pp. 169–174, 8 figs. Development of 800 hp. for metallurgical works.

New England. Rebuilding an Old New England Water-Power Plant, E. H. Swett. Eng. News-Rec., vol. 86, no. 25, June 23, 1921, pp. 1062–1066, 6 figs. Special construction problems in new hydroelectric station for Jackson mills long supplied with power from individual wheels taking water from Nashua River.

Niagara Falls. Hydroelectric Development at Niagara Falls, John L. Harper and J. A. Johnson Jl. Am. Inst. Elec. Engrs., vol. 40, no. 7, July 1921, pp. 561–576, 33 figs. Also abstracts in Power, vol. 54, no. 1, July 5, 1921, pp. 26–28, 6 figs. Historical survey. Possibility of more efficient utilization of water power available for development according to international treaty, which permits utilization of 20,000 cu. ft. per sec. on American side and 36,000 cu. ft. per sec. on Canadian side.

Northwestern U. S. Electrical Construction Work in Northwestern States, W. A. Scott. Elec. Rev., (Chicago), vol. 79, no. 1, July 2, 1921, pp. 11–12, Expansion and reconstruction of hydroelectric plants.

I

ICE PLANTS

Brine Tanks. Concrete Brine Tanks, H. C. Boyden. A.S.R.E. Jl., vol. 7, no. 5, Mar. 1921, pp. 390–400. Advantages of concrete brine tanks. Principles that should be observed in their design.

South Chicago. Consumers New Ice Plant at South Chicago, Gilbert Sellers. Power, vol. 53, no. 26, June 28, 1921, pp. 1038–1040, 3 figs. Synchronous-motor-driven ammonia compressors require 25.8 kw-hr. per ton of ice.

INDICATORS

Internal-Combustion Engines. A Pressure Indicator for Internal Combustion Engines, J. Okill. Power, vol. 54, no. 1, July 5, 1921, pp. 10–11, 2 figs. Modified form of steam-engine indicator.

INDUSTRIAL MANAGEMENT

Germany. The Taylor System and Scientific Management in Germany (Das Taylor-System und die deutsche Betriebswissenschaft), G. Schlesinger. Werkstattstechnik, vol. 15, no. 11, June 1, 1921, pp. 313–317. Discusses form in which Taylor system and the Gilbreth motion studies can best be adapted to German conditions.

Graphic Methods. The Ratio Chart and Its Applications—I, Percy A. Bivins. Indus. Management, vol. 62, no. 1, July 1, 1921, pp. 10–14, 11 figs. Exposition of construction and uses of ratio charts.

Personnel. Personnel Management of the Metropolitan Life Insurance Co., Lawrence Washington. Indus. Management, vol. 62, no. 1, July 1, 1921, pp. 27–32, 8 figs.

Production Systems. Analyzing Tool Production Problems, Albert A. Dowd and Frank W. Curtis. Iron Age, vol. 107, no. 25, June 23, 1921, pp. 1671–1673, 9 figs. Method of analysis. Results of alternative methods of machining and set-up.

Budgeting Business, Park Mathewson. Indus. Management, vol. 61, no. 11, June 1, 1921, pp. 404–407, 3 figs. Planning production quotas by means of budget system.

Graphic Production Control for the Small Shop, R. J. Rahn. Indus. Management, vol. 61, no. 11, June 1, 1921, pp. 432–436, 3 figs. Control sheet.

How and Why Production Methods Increase Shop Production, E. T. Spidy. Jl. Eng. Inst. of Canada, vol. 4, no. 7, July 1921, pp. 404–408, 5 figs. General outline of modern production methods, with particular emphasis on importance of shop schedule.

The Economy of Standard Quantities, Paul E. Holden. Indus. Management, vol. 62, no. 1, July 1, 1921, pp. 34–36, 2 figs. Avoiding too frequent machine set-ups and unbalanced stocks.

Rate Setting. Serial Rate-Setting, H. P. Losely. Indus. Management, vol. 61, no. 11, June 1, 1921, pp. 409–415, 10 figs. Determining time rates on varying sizes of similar parts.

Stores Organization. Stores Organisation. Eng. Production, vol. 2, no. 38, June 23, 1921, pp. 739–742, 9 figs. Forms for keeping records.

[See also TIME STUDY.]

INDUSTRY

Selection of Industrial Sites. Choosing the New Plant Location, H. H. McCanna. Indus. Management, vol. 61, no. 11, June 1, 1921, pp. 396–398, 2 figs. Factors affecting selection of industrial sites.

INSPECTION

Managing Department. Managing an Inspection Department, George S. Radford. Indus. Management, vol. 61, no. 11, June 1, 1921, pp. 422–426, 1 fig. How to handle personnel and routine.

Methods. The Delco Inspection System, Louis Ruthenburg. Machy. (Lond.), vol. 18, no. 454, June 9, 1921, pp. 289–293, 4 figs. Methods used by Dayton Engineering Laboratories Co. for inspection of raw meterials, purchased parts, tools, equipment and gages, and manufactured product.

INTERNAL-COMBUSTION ENGINES

Temperature Measurement. Measuring Temperatures in Internal-Combustion Engines (La tecnica delle misure di temperatura nei motori a combustione interna), P. Ferretti. Rivista Marittima, vol. 54, no. 1, Jan. 1921, pp. 41–102, 37 figs. Describes hydrogen gas thermometer, resistance thermometer and Callendar, Burstall, Peterson and Wolff instruments and various results obtained by these experimenters. Deals in detail with thermoelectric thermometer and experience of Bams, Stronhal and others with this apparatus. Bibliography.

[See also ALCOHOL ENGINES; AEROPLANE ENGINES; AUTOMOBILE ENGINES; DIESEL ENGINES; INDICATORS, Internal-Combustion Engines; MARINE ENGINES, Oil; REFRIGERATING PLANTS.]

IRON

Bars, Fractures in. Unusual Fractures in Iron Bars (Merkwürdige Brucherscheinungen bei Eisenstäben), J. Grimme. Zeit. des Vereines deutscher Ingenieure, vol. 65, no. 23, June 4, 1921, pp. 603–604, 12 figs. Results of tests with iron bars which were stressed during several hundred hours. Cause for the regularly occurring fracture without defects in material has not yet been found.

Magnetic Properties. Magnetic Properties of Compressed Powdered Iron, Buckner Speed and G. W. Elmen. Jl. Am. Inst. Elec. Engrs., vol. 40, no. 7, July 1921, pp. 596–609, 22 figs. Magnetic material specially suited to construction of cores in small inductance coils and transformers such as used in telephone plants. Material is formed by grains of powdered iron, insulated and compressed. Tables and curves are given showing magnetic, electrical and mechanical properties of material.

IRON ALLOYS

Magnetic Properties. On the Influence of Low Temperatures on the Magnetic Properties of Alloys of Iron with Nickel and Manganese, Kamerlingh Onnes, Robert A. Hadfield and H. R. Woltjer. Proc. Royal Soc., vol. 99, no. A698, June 1, 1921, pp. 174–196, 11 figs. Experiments showed that iron-manganese alloys, containing higher percentages of manganese, cannot be made magnetic at atmospheric temperature by cooling to boiling point of liquid hydrogen or liquid helium.

IRON CASTINGS

Cleaning. Cleaning and Dressing Castings, F. W. Wilson. Engineering, vol. 111, no. 2893, June 10, 1921, pp. 725–727. 13 figs. Procedure and equipment. Paper read before Manchester Assn. Engrs.

IRON INDUSTRY

Germany. German Iron and Steel in Reconstruction, H. Cole Estep. Iron Trade Rev., vol. 69, no. 1, July 7, 1921, pp. 25–30, 3 figs. Pig-iron production in first 5 months of 1921 was 6,000,000 metric tons; steel ingot production, 6,400,000 metric tons. Corresponding figures for 1913 were 19,300,000 and 18,940,000 metric tons.

J

JIGS

Design. Tool Engineering, Albert A. Dowd and Frank W. Curtis. Am. Mach., vol. 54, nos. 25 and 26, June 23 and 30, 1921, pp. 1078–1080, 5 figs., and 1119–1122, 7 figs. June 23: Closed jigs for annular and straight holes. Locating and assembling jigs. June 30: Design of drill jigs, indexing and trimming jigs; drilling and reaming indexing fixtures and four-sided jigs for accurate work.

Tool Engineering, Albert A. Dowd and Frank W. Curtis. Am. Mach., vol. 55, no. 1, July 7, 1921, pp. 18–22, 11 figs. Design of drill jigs. Principles and methods of indexing. Index plungers and latches. Combined index and latch. Specific examples of indexing jigs.

L

LABOR

Italy. Labor Unrest in Italy, Alfred Maylander. U. S. Dept. of Labor, Monthly Labor Rev., vol. 12, no. 6, June 1921, pp. 137–259. Rôle played by labor organization and political bodies in present unrest among industrial and agricultural labor. Extent to which economic causes have operated to bring about labor unrest, and measures that have been taken to abate it. Developments in syndicalist control of industries.

LABORATORIES

Research. The Rudge-Whitworth Research Laboratory. Machy. (Lond.), vol. 18, no. 454, June 9 1921, pp. 301–303, 5 figs. Measuring instruments developed at research laboratory of Rudge-Whitworth Manufacturers of steel balls, ball bearings, pedal and motorcycles and detachable wire wheels.

LATHE WORK

Time Allowances. Suggestions for Turning Operations (Drehakkorder), F. Lohage. Werkstattstechnik, vol. 15, no. 12, June 15, 1921, pp. 355–358, 4 figs. Notes in determination of working time for turning operation, turning spindles and bolts, and cutting threads on lathe. Includes table for determination of working time for cutting Whitworth threads.

LATHES

Relieving. The Importance of Relieving Lathes in High-Grade Machine Construction (Die Bedeutung der Hinterdrehbank für den hochwertigen Maschinenbau), C. E. Berck. Der praktische Maschinen-Konstrukteur, vol. 54, no. 22, June 2, 1921, pp. 89–92, 15 figs. Details of lathe constructed by Schüttoff & Bässler, Chemnitz, Germany, for backing off the teeth of milling cutters, hobs, etc.

LIGNITE

Briquetting. Fuel Loss through the Briquetting of Lignite (Der Brennstoffverlust durch die Brikettierung der Braunkohle), H. Berner. Chemiker-Zeitung, vol. 45, no. 42, Apr. 7, 1921, pp. 333–335. It is shown that fuel consumed in briquet factory does not represent fuel loss, and results of calculations show that from original fuel consumption in factory of from 17 to 31 per cent. the actual fuel loss due to savings through heat used for drying, etc., is only about 8 per cent. Report of expert committee of Central German Lignite Syndicate.

German Industry. The Rhenish Lignite Industry. (Grundlinien der rheinischen Braunkohlenindustrie), Rudolf Adrian. Braunkohle, vol. 19, nos. 31, 32, 33, 35 and 36, Nov. 13, 20, 27, Dec. 11, and 18, 1920, pp. 381–384, 394–399, 407–411, 431–434 and 445–447. Points to increasing importance of Rhenish lignite in comparison to anthracite as fuel. Long-distance supply of electric energy from the lignite mines; organization of the Lignite Briquet Sales Assn., its effects on prices, production, etc. Suggestions for future development; transportation problem.

Research. Researches upon Brown Coals and Lignites. Part I—Heat Treatment at Temperatures below 400 Deg. C. as a Possible Method for Enhancing Their Fuel Values, William A. Bone. Proc. Royal Soc., vol. 99, no. A698, June 1, 1921, pp. 236–251. Treatment was found to improve fuel values of brown coals and lignites.

LOCOMOTIVE BOILERS

Heat Transmission in Flues. Heat Transfer in Flues—a Graphic Method of Calculation, A. J. V. Umanski. Engineering, vol. 111, no. 2893, June 10, 1921, pp. 702–703, 2 figs. Graphs for computing temperature drop in flues of various diameters.

LOCOMOTIVES

Baldwin Locomotive Works. Baldwin Builds Forty Locomotives for Southern Pacific. Ry. Rev., vol. 68, no. 26, June 25, 1921, pp. 966–968, 3 figs. Pacific type, 2–10–2 type for heavy freight traffic and switching locomotives.

Canadian Pacific Railway. A Locomotive Designed for Rigorous Operating Conditions, W. H. Winterrowd. Ry. Rev., vol. 68, no. 25, June 18, 1921, pp. 929–936, 14 figs. Pacific type locomotive designed for Canadian Pacific Ry. Characteristics: Cylinder, diameter and stroke, 25 in. by 30 in.; boiler pressure, 200 lb. per sq. in.; diameter drivers, 75 in.; weight engine, total 299,000 lb.; heating surface, total 3529.6 sq. ft.

Consolidation Type. Consolidation Locomotives for the Western Maryland. Ry. Mech. Engr., vol. 95, no. 7, July 1921, pp. 419–422, 8 figs. Characteristics: Cylinders, 27 in. by 32 in; boiler type, straight top; boiler diameter, 88 in.; working pressure, 210 lb. per sq. in.; tractive effort, 68,200 lb.; total weight, 294,900 lb.

The New Consolidation Locomotive of the Belgian State Railway (Les nouvelles locomotives "Consolidation" des chemins de fer de l'etat belge), M. E. Minsart. Bulletin technique de l'Association des Ingénieurs sortis de l'Ecole Polytechnique de Bruxelles, vol. 17, no. 2, 1920–1921, pp. 117–127, 3 figs. Manufactured in America. Characteristics: Cylinders, 610 mm. diameter by 711 mm. stroke; interior diameter of boilers, 1727 mm.; heating surface, total, 172.2 sq. m.; superheating, 51.1 sq. m.; total weight in working order 84500 kg.; tractive effort at 65 per cent of boiler pressure, 15,840 kg.

Cut-off Control. The Automatic Control of Locomotive Cutoff, E. S. Pearce. Ry. Age, vol. 70, no. 25, June 24, 1921, pp. 1451–1456, 11 figs. Tests conducted by Big Four Ry.

Driving Wheels. Methods Used in Locomotive Driving Wheels, Axle and Crankpin Work, Frank A. Stanley. Am. Mach., vol. 54, no. 25, June 23 1921, pp. 1070–1072, 8 figs. Present practice on several classes of work in Southern Pacific shops. Allowance required for shrinking tire on driving wheels.

Feedwater Heating. Developments in Locomotive Feed Water Heating. Ry. Rev., vol. 69, no. 2, July 9, 1921, pp. 44–46, 3 figs. Refinements in design facilities return of condensate to feedwater and elimination of water stops.

Locomotive Feedwater Heating (Die Speisewasservorwärmung im Lokomotivbetriebe), R. Sanzin. Verkehrstechnik, vol. 38, no. 7, Mar 5, 1921, pp. 85–87. Advantages of feedwater heating. Drummond, Caille-Potonié, Worthington and Knorr systems.

Power of Increasing. Vitalizing Locomotives, George M. Basford. Official Proc. New York Railroad Club, vol. 31, no. 7, May 20, 1021, pp. 646, 12 figs. Increasing power of locomotives as means for remedying transportation congestion.

Repairs. Manufacturing Standard Locomotive Repair Parts, M. H. Williams. Ry. Mech. Engr., vol. 95, no. 7, July 1921, pp. 451–455, 7 figs. Method of standardizing and manufacturing locomotive repair parts in central production shops.

Shops. Railway Machine Shop Practice — I. Machy. (Lond.), vol. 18, no. 455, June 16, 1921, pp. 312–325, 12 figs. Methods employed in locomotive shops of Great Western Ry. Co., England.

Speed Indicators. The Best Relative Variable in Registration of Speed in Railway Operation (Die zweckmässigste Bezugsvariable bei der Geschwindigkeitsregistrierung im Eisenbahnbetrieb), W. Hort. Verkehrstechnik, vol. 38, no. 1, Jan. 5, 1921, pp. 1–3, 4 figs. Diagrams measured with different speed indicators comparing use of time or

distance as relative variable. In Bruhn system distance and speed are recorded directly whereas time acceleration and retardation are computed from diagram.

Superheater. Pyrometers Promote Locomotive Efficiency. Ry. Mech. Engr., vol. 95, No. 7, July 1921, pp 433, 2 figs. Tests showing values of pyrometers applied to superheater locomotives.

Spiral Tubes and Superheaters in Connection with Fuel Economy in Steam Locomotives and Fire-Tube Boilers (Essrohre und Spiralüberhitzer und Brennstoffersparnis bei Dampflokomotiven und Heizröhrenkesseln), K. E. Nordling and R. Bengtzon. Analen für Gewerbeu. Bauwesen, vol. 88, no. 10, May 15, 1921, pp. 83–87, 3 figs. Spirally corrugated tube known as the Ess tube, manufactured by the Uddeholms Aktiebolag, Uddeholm, Sweden.

Valve Gear. Poppet-Valve Gear for Steam Locomotives (Ventilsteuerung für Dampflokomotiven), H. Wittfeld. Zeit. des Vereines deutscher Ingenieure, vol. 65, no. 24, June 11, 1921, pp. 623–625, 10 figs. Describes Lentz valve gear which can be installed in existing locomotives in place of piston valves without alteration of cylinder and driving rod. Results of extended experimental operation.

LUBRICATING OILS

Mineral. The Improvement of the Lubricating Properties of Mineral Oils, J. H. Hyde. Engineering, vol. 111, no. 2893, June 10, 1921, pp. 708–709, 10 figs. Improvement of lubricating properties of mineral oils by addition of fatty oils and acids. From experiments conducted at British Nat. Physical Laboratory.

Research. Investigation into Properties of Lubricating Oils. Automotive Industries, vol. 45, no. 1, July 7, 1921, pp. 16–17. Report of tests made by British committee covers measurement of coefficient of friction at various temperatures and with oils of various viscosities. Comparisons of vegetable, animal and mineral oils with and without addition of refined or deflocculated graphite are included.

Tests. Endurance Test of Force Feed Oils, J. G. O'Neill. Jl. Am. Soc. of Naval Engrs., vol. 33, no. 2, May 1921, pp. 248–260, 9 figs. It is concluded that mineral lubricating oils, derived from asphaltic base crude or paraffin base crude and of same viscosity at operating temperatures, will give same service in force-feed lubrication system.

LUBRICATION

Bearings. Oil Consumption and Friction Losses (Oelverbrauch und Reibungsverluste), W. Torau. Verkehrstechnik, vol. 38, no. 6, Feb. 25, 1921, pp. 75–76, 2 figs. Lubricating device said to have been successfully used in transmission-gear construction, machine tools, etc. Device is suitable for railway cars and their drives.

Tests. Measures for Improvement of Lubrication on the Berlin Street Railway (Massnahmen zur Verbesserung des Schmiermittelverbrauchs bei der Berliner Strassenbahn), H. Simmrock. Elektrische Kraftbetriebe u. Bahnen, vol. 19, no. 10, May 24, 1921, pp. 114–115. Results of tests with lubricants and lubricating devices carried out with a view to devising method for reducing consumption of oil.

M

MACHINE SHOPS

Power-Plant. Power Plant Machine Shops, W. O. Rogers. Power, vol. 54, no. 1, July 5, 1921, pp. 12–19, 26 figs. Machine tools found in use in representative power-plant machine shops.

Railways. Railway Machine Shop Practice—II Machy. (Lond.), vol. 18, no. 456, June 23, 1921, pp. 349–351, 6 figs. Methods employed in locomotive shops of Great Western Ry. Co., England.

Railway Machine Shop Practice—IV. Machy. (N. Y.), vol. 27, no. 11, July 1921, pp. 1015–1017, 7 figs. Methods used in machining crown brasses, driving-boxes, and shoes and wedges.

MACHINE TOOLS

Drive. Machine-Tool Driving, J. D. Hope. Mech. World, vol. 69, no. 1798, June 17, 1921, Pp. 459–460. Individual electric driving arrangements versus group system of driving.

MALLEABLE IRON

Casting. American Malleable Cast Iron—XIII, H. A. Schwartz. Iron Trade Rev., vol. 68, no. 26, June 30, 1921, pp. 1792–1797, 5 figs. Electric furnace melting. Kranz triplex process.

MARINE BOILERS

Manufacture. Marine Boiler Construction—II. Machy. (Lond.), vol. 18, no. 454, June 9, 1921, pp. 295–300, 12 figs. Methods and machines employed in representing English shops.

MARINE ENGINES

Oil. Modern Marine Oil Engines—I. Engineer, vol. 131, no. 3416, June 17, 1921, pp. 633–635 and 644, 5 figs. Doxford 3000-i.hp. opposed-piston type.

MEASURING INSTRUMENTS

Internal Measurements. New Light on Internal Measurements, John Bath. Am. Mach., vol. 54, no. 26, June 30, 1921, pp. 1110–1114, 4 figs. Forms of contacts for measuring cylindrical surfaces. Results induced by presence of oil on surfaces in contact.

Pneumercator. The Pneumercator System. Ship building & Shipping Rec., vol. 17, no. 24, June 16, 1921, pp. 745–746, 5 figs. Method of recording height or weight of liquid at distant point.

METAL DRAWING

Seamless Vessels. The Drawing of Seamless Vessels and the Tools Therefor (Das Ziehen von nahtlosen Gefässen und die Werkzeuge hierfür), Alfred Wildner. Der praktische Maschinen-Konstrukteur, vol. 54, no. 22, June 2, 1921, pp. 93–95, 1 fig. General rules are set forth and suitable tools described.

METALS

Calorizing. Treating Metal to Resist Heat, Arthur V. Farr. Iron Trade Rev., vol. 68, no. 25, June 23, 1921, pp. 1724–1727, 13 figs. Calorizing process. Material is placed in rotary retort which contains finely divided aluminum, and there heated in reducing atmosphere. Resultant alloy surface is thus formed that withstands abrasion.

METEOROLOGY

Cloud Systems. Cloud Systems (Sur les systèmes nuageux), Ph. Schereschewsky. Comptes rendus des Séances de l'Académie des Sciences, vol. 172, no. 23, June 6, 1921, pp. 1429–1431. Method of studying cloud systems. International classification.

Weather Forecasting. Weather Forecasting (Le probleme de la prevision du temps), L. Dunoyer and G. Reboul. Journal et Physique et le radium, vol. 2, no. 5, May 1921, pp. 129–131, 1 fig. Experience of Meteorological Service of French army.

METRIC SYSTEM

apan. The Metric System in Japan, J. H. Blakey. Power Plant Eng., vol. 25, no. 13, July 1, 1921, pp. 673. Obligatory adoption of metric system in Japanese empire. Translated from Comptes rendus de l'Académie des Sciences.

MILLING CUTTERS

Screw-Thread. Helical Cutters for Milling Screw Threads (Rilleofräser zur Gewindeherstellung). Der praktische Maschinen-Konstrukteur, vol. 54, no. 12, Mar 24, 1921, pp. 51–56, 8 figs. Shows why such cutters should be made only with straight chip flutes. Reprinted in full from Loewe-Notizen, published by Ludw. Loewe Corp.

MILLING MACHINES

Drum Type. Manufacturing Applications of Ingersoll Drum-Type Milling Machines, J. V. Hunter. Am. Mach., vol. 55, no. 1, July 7, 1921, pp. 23–27, 21 figs. Fixtures for holding work. Automatic clamping devices.

MOLDING METHODS

Green Sand. Costs Dictate Changes in Molding, Pat Dwyer. Foundry, vol. 49, no. 13, July 1, 1921, pp. 501–509, 16 figs. Experience of Muncie Foundry & Machine Company, Muncie, Ind. Dry sand has been abandoned in favor of green-sand method for molding automobile cylinders.

MONEL METAL

Latent Heat of Fusion. The Latent Heats of Fusion of Nickel and Monel Metal, Walter P. White. Chem. and Met. Eng., vol. 25, no. 1, July 6, 1921, pp. 17–21. Experimental determination of latent heats of nickel and monel metal and of their specific heats for intervals to 1360 and 1260 degs. cent., respectively. Latent heat of nickel was 73 calories per gram and that of monel metal 68 calories per gram.

MOTOR BUSES

Operation. Akron's Motor Bus Route. Elec. Ry. Jl., vol. 57, no. 26, June 25, 1921, pp. 1164–1167, 7 figs. Non-competitive route operated in connection with housing development.

Trolley. Electrification at Edinburgh. Elec. Ry. Jl., vol. 58, no. 1, July 2, 1921, pp. 12–14, 3 figs. Gasoline motor buses and electric railway cars replace cable operation. Choice was determined by traffic power and price conditions.

Pioneer Trackless Trolley Installation. Elec. Ry. Jl., vol. 57, no. 26, June 25, 1921, pp. 1158–1161, 7 figs. Experimental trolley buses operated in conjunction with rail service at Richmond, Va.

Trackless Trolley Line in Austria (Elektrische Oberleitungs-Automobillinie Pötzleinsdorf-Salmanns dorf), Ernst Findeis. Elektrotechnik u. Maschinenbau, vol. 39, no. 22, May 29, 1921, pp. 270–271, 1 fig. Interurban bus line in vicinity of Vienna with overhead current supply, according to Austro-Daimler-Stoll system, in use since 13 years, with less cost of installation and operation than in the case of street-railway line and gasoline-burning buses. Address before Int. Street and Narrow-Gage Ry. Congress, Vienna.

MOTOR PLOWS

German. Modern German Motor Plows (Neuere deutsche Motorpflüge), Richard Bussien. Oel- u. Gasmaschine, vol. 18, no. 6, June 1921, pp. 81–96, 21 figs. Details of various types.

MOTOR TRANSPORT

Trains. A Self-Propelled Highway Freight Train of 30-tons Net Load (Der Müllerzug), E. Fränkel. Verkehrstechnik, vol. 38, no. 13, May 5, 1921, pp. 165–170, 5 figs. The separate trucks, which are electrically driven by current generated in leading truck by a steam or internal-combustion engine, run in track of first car, due to a special stearing gear. Use of train as feeder for railway lines and for testing traffic in planned routes not yet built. Trains with heavy steam cars in England reached a speed of 10 to 12 km. per hr. on a 70-km. stretch.

MOTOR TRUCKS

Leyland Steam Wagon. The Leyland Steam Wagon, Engr., vol. 131, no. 3415, June 10, 1921, pp. 616–617, 7 figs. Hydraulic tipping steam wagon manufactured by Leyland Motors, Ltd., Leyland, England.

Manufacture. Fits, Tolerances and Heat Treatments Applied in Production, C. T. Bates. Automotive Industries, vol. 44, no. 24, June 16, 1921, pp. 1314–1326, 9 figs. Data covering actual practice employed by many manufacturers in production of all parts used in heavy truck. Same fits, tolerances and heat treatments are applicable in production of parts for passenger cars, light trucks and other automotive vehicles.

MOTORCYCLES

British. Review of Engineering Features of British Motorcycles, M. W. Bourdon. Automotive Industries, vol. 44, no. 25, June 23, 1921, pp. 1376–1381, 6 figs. Types exhibited at Olympia show.

MOTORSHIPS

German-Built. Germany to Build High Powered Diesels. Mar. Eng., vol. 26, no. 7, July 1921, pp. 545–547, 3 figs. Motorship under construction in Germany that is to carry two 3000-b.hp. Sulzer Diesel engines.

N

NICKEL

Plating Solutions. "Black Nickel" Plating Solutions, George B. Hobagoom, T. F. Slattery and L. B. Ham., U. S. Dept. of Commerce, Bur. of Standards, Technologic Papers, no. 190, April 4, 1921, 9 pp. Results of experiments on plating solutions used to produce "government bronze" finish on military hardware.

NON-FERROUS METALS

Ship Construction. Non-Ferrous Metals and Compositions, Horace Holden Thayer. Mar. Eng., vol. 26, no. 7, July 1921, pp. 524–533. Composition of metals used in ship construction. Table of brasses, bronzes and bearing metals for ship specifications.

O

OIL FIELDS

Argentina. Geological Study of Comodoro Rivadavia Oil Fields Being Exploited by Argentina Government (Estudio geológico de la zona de reserva de ea explotación nacional de petróleo en Comodoro Rivadavia), Ricardo Wichmann. Ministerio de Agricultura de la Nación, bul. no. 25, 1921, 19 pp., 3 figs.

India. Petroleum in the Punjab and North-West Frontier Province, E. H. Pascoe. Memoirs of Geological Surveyof India, vol. 40, part 3, 1920, 493 pp., 20 figs. Geological and physical features of oil fields.

Mexican. The Production and Combustion of Mexican Fuel Oil—II, J. M. Pettingell and J. R. Carlson. Combustion, vol. 4, no. 6, June 1921, pp. 18–23, 9 figs. Notes on drilling wells and transporting oil.

Peru. Peruvian Oil Fields, Vernon F. Marsters. Eng. & Min. Jl., vol. 111, no. 26, June 25, 1921, pp. 1073–1075, 1 fig. Geological description of fields and statistics of production.

Spain. Petroleum in Spain (Petroleos en España), Pablo Fábrega. Revista minera metalurgica y de Ingenieria, vol. 72, no. 2782, May 1, 1921, pp. 245–247. Account of explorations.

OIL FUEL

Coal vs. Relative Efficiencies with Coal and Fuel Oil, A. W. Darter. Power Plant Eng., vol. 25, no. 13, July 1, 1921, p. 657. Comparative boiler tests with Texas lignite and with Mexican fuel oil.

OIL SHALES

Distillation. A Study of the Saturated and Unsaturated Compounds of Shale Oils, C. W. Botkin. Petroleum Times, vol. 5, no. 126, June 4, 1921, pp. 659–663. Determination of saturates and unsaturates. Distillations of crude asphaltic shale oil. Effect of distillation of oil on saturates and unsaturates and their distillation.

The Distillation of Oil Shale, A. H. Low. Petroleum Times, vol. 5, no. 127, June 11, 1921, pp. 689–690, 1 fig. Method adopted in Colorado School of Mines.

Testing. Anglo-Persian Activity in New Brunswick Oil Shales, Alexander Gray. Can. Min. Jl., vol. 42, no. 24, June 17, 1921, pp. 474–479. Eight ton testing plant in operation. Technical staffs to be increased and larger plans to be framed when results satisfactory.

P

PARACHUTES

Types. New Types of Parachutes, Alfred Gradenwitz. Aviation, vol. 11, no. 1, July 4, 1921, pp. 22, 3 figs. Designs developed by German army.

PETROLEUM INDUSTRY

By-Products. The Development of an Oil By-Product Industry, Eric K. Rideal. Chem. Age. (Lond.), vol. 4, no. 104, June 11, 1921, pp. 666–668. Possibility of establishing by-product industry in connection with oil in much the same way as is done with coal.

PIPE LINES

Hot-Oil Transportation. Pipe-Line Transportation of Hot Oil, Leonard L. Barrett. Chem. & Metallurgical Eng., vol. 24, no. 26, June 29, 1921, pp. 1148–1152, 3 figs. Study of thermal losses in hot petroleum transit lines. Calculations based on d'Arcy's hydraulic formula for spacing pumping and heating stations. Curves of hydraulic gradient for insulated and uninsulated 8-in. lines.

PIPE, STEEL

Centrifugally Cast. Mold Serves as Electric Furnace, E. C. Kreutzberg. Iron Trade Rev., vol. 69, no. 1, July 7, 1921, pp. 33–35, 6 figs. Cammen patented process. Metal is melted electrically in the same mold in which it is cast. Process will be used at plant of Metal Alloys Co., Elizabeth, N. J., for manufacturing aluminum-bronze tubes of all diameters.

PISTONS

Aluminum. Problems and Possibilities of the Aluminum Piston, Walter Rosenhain. Automotive Industries, vol. 44, no. 24, June 16, 1921, pp. 1264–1266 and 1301. Advantages of and limitations of aluminum piston for automobile and aeroplane engines.

Crank-Driven. Results Obtained with Crank-Driven Planers, Edward K. Hammood. Machy. (N. Y.), vol. 27, no. 11, July 1921, pp. 1052–1056, 9 figs. Methods of operating machines possessing features of both planer and shaper.

PLANING

Production System. Production Planing in Machine Tool Plants. Machy. (Lond.), vol. 18, no. 455, June 16, 1921, pp. 326–330, 6 figs. Importance of using adequate number of stops in setting up planer work. Tables of planing speeds and feeds for roughing cuts in various materials.

POLES, WOODEN

Specifications. British Standard Specification for Red Fir Wood Poles for Telegraph and Telephone Lines, British Eng. Standards Assn., no. 139, Feb. 1921, 8 pp. Methods of creosoting.

PLATES

Deflection. The Deflection of a Rectangular Plate under Single Loads (Ueber die Biegung der rechteckigen Platte durch Einzellasten), A. Nádai. Bauingenieur, vol. 2, no. 11, June 15, 1921, pp. 299–304, 6 figs. Determination of deflection and distribution of stress in a fixed-in plate strip with concentrated load. Application to different cases of stress in rectangular plates.

Stresses. Strength of Flat Elliptical Plate Loaded Uniformly and Supported at the Perimeter, Tzuruzo Matsumura. Jl. Soc. Mech. Engrs., Tokyo, Japan, vol. 24, no. 68, May 1921, pp. 31–40, 1 fig. Calculations.

PULVERIZED COAL

Application to Boilers. Pulverized-Coal Furnaces for Steam Boilers (Die Kohlenstaubfeuerung für Dampfkessel), F. Schulte. Glückauf, vol. 57, no. 18, Apr. 30, 1921, pp. 413–419, 4 figs. Describes plants for drying and crushing of coal and for conveying of pulverized coal to furnace burners. Favvorable and unfavorable conditions for burning pulverized coal.

Boiler Firing. Boiler Tests with Pulverized Illinois Coal, Henry Kreisinger and John Blizard. Coal Industry, vol. 4, no. 6, June 1921, pp. 291–293, 2 figs. Results of series of 11 tests made on 468-hp. Edgemoor boiler equipped with Foster superheater and fired with pulverized coal. Tests were made by Fuel Section of U. S. Bur. of Mines in coöperation with Research Dept. of Combustion Eng. Corp. Results indicated that it is not necessary to pulverize to fineness of 85 per cent through 200 mesh screen in order to obtain efficiency.

Operation with Pulverized Coal, A. J. Dixon. Power, vol. 54, no. 1, July 5, 1921, pp. 24–25, 1 fig. Test to determine commercial efficiency of pulverized coal as boiler fuel being conducted at power plant of Rialto Bldg., St. Louis, Mo.

Oil Fuel on Hull Tramways: Comparison with Coal Consumption, E. S. Rayner. Tramway & Ry. World, vol. 49, no. 830, June 16, 1921, pp. 289–293. Comparative cost and results of operating boilers in power house 14 days under oil fuel and 14 days under coal.

Pulverized Firing in Steam Generation, F. J. Crolius. Assn. Iron & Steel Elec. Engrs., vol. 3, no. 6, June 1921, pp. 161–168 and ((discussion) pp. 188–198. Survey of developments. Classification of methods into indirect firing and direct firing. Design of combustion chambers. Economies of using pulverized coal.

Stoker Firing vs. Pulverized Coal versus Stoker Firing, F. P. Coffin. Power, vol. 54, no. 2, July 12, 1921, pp. 52–54, 2 figs. From forthcoming book on "The Utilization of Coal on a Multiple-Products Basis."

Uses. Heating with Pulverized Coal (Le chauffage au charbon pulvérisé), P. Frion. Chaleur et Industrie, vol. 2, no. 13, May 1921, pp. 278–284. Survey of developments on Europe and America. (To be continued.) Report prepared under auspices of French Interministerial Committee appointed to study best utilization of fuels.

Industrial Heating with Pulverized Coal (Le chauffage industriel au charbon pulvérisé), Paul Frion. Revue générale de l'Électricité, vol. 9, nos. 23 and 24, June 4 and 11, 1921, pp. 817–824 and 856–862. Typical installations. Advantages of pulverized coal and possibilities of its application in various industries. (Concluded.) Report of French Interministerial Committee appointed to study best utilization of fuels.

Use of Pulverized Coal for Heating Furnaces and Boilers (L'emploi du charbon pulvérisé pour le chauffage des fours et des chaudières). Génie Civil, vol. 78, no. 22, May 28, 1921, pp. 459–462. Developments in Europe and America. Report of Committee on Economical Combustion of Fuel, appointed by French Government. From Journal Officiel.

PUMPING ENGINES

Corliss. Triple Corliss Pumping Engine for Margate Waterworks. Engr., vol. 131, no. 3414, June 3, 1921, pp. 588–590, 5 figs. Hathorn, Davey & Co. standard vertical triple Corliss pumping engine forcing water to surface from depth of 130 ft. and forcing it a distance of nearly 15 miles against head of 300 ft.

PUMPS

Rotary Exeter. Suction Pump Operates upon New Principle. Iron Trade Rev., vol. 68, no. 25, June 23, 1921, pp. 1723, 2 figs. Description of Exeter rotary pump manufactured by Exeter Machine, West Pittston, Pa.

Turbine-Driven. Jennings Turbine-Driven Return-Line Heating Pump. Power, vol. 54, no. 1, July 5, 1921, p. 6, 3 figs. Designed for use in connection with heating or drying systems.

PUMPS, CENTRIFUGAL

Design. Increased Output with Centrifugal Pumps and Blowers (Gesteigerte Leistung bei Schleuderpumpen und -gebläsen), Edmund Pocher. Fördertechnik u. Frachtverkehr, vol. 14, no. 11, May 27, 1921, p. 119–121, 7 figs. Discusses inflow and outflow in suction and pressure pipes of pumps and blowers, and use of suction funnels and conical pressure pipes and diffusors, advantages of which are demonstrated. Deals also with inflow and especially outflow from impeller and emphasizes importance of experimental results for internal design of pumps and blowers.

Efficiency. New Method of Determining Efficiency of Centrifugal Pumps, Allen F. Sherzer. Eng. News-Rec., vol. 86, no. 26, June 30, 1921, pp. 1114–1115, 3 figs. Efficiency contours for centrifugal pumps in terms of gallons per minute and specific speeds. Graphs showing relation between capacity and efficiency and relation between specific speeds and efficiency for horizontal centrifugal pumps.

Water Leakage. On the Leakage of Water through the Clearance Rings in a Centrifugal Pump, Otogoro Miyagi. Jl. Soc. Mech. Engrs., Tokyo, Japan, vol. 24, no. 68, May 1921, pp. 15–29, 3 figs. Technical study.

R

RAILS

Alloy-Steel. On the Question of Special Steels, W. C. Cushing. Bul. Int. Ry. Assn., vol. 3, no. 6, June 1921, pp. 577–640. Comparative study of suitability of various steel alloys for rail manufacture, from records of experience of railways in different parts of the world.

Hardening "In Situ." The Sandberg "In Situ" Rail Hardening Process, A. E. Shirter. Acetylene Jl., vol. 23, no. 1, July 1921, pp. 15–17, 2 figs. Hand propelled truck fitted with equipment for heat-treating rails by blowpipes. Experience of British Electric Railway.

Wooden. The Widegren Wooden Rail System (Transportbane - System Widegren), K. A. Widegren. Teknisk Tidskrift (Veckoupplagean), vol. 51, no. 14, Apr. 9, 1921, pp. 161–164, 7 figs. Track consists of roughly hewn beams, resting on a trestle or ties. Wheels have rubber tires without flanges. Railway has proved to be very safe; trucks run smoothly, wear and tear is not great, and cost of installation is about 35 to 50 per cent that of steel railways.

RAILWAY ELECTRIFICATION

Brazil. Electrification of the Paulista Railway, Brazil, S. A. W. D. Bearce. Gen. Elec. Rev., vol. 24, no. 7, July 1921, pp. 620–627, 7 figs. Motor power equipment consists of eight freight locomotives weighing 100 tons each and four passenger locomotives weighing 120 tons each.

Substituting Water Power for Wood Fuel in Brazil, W. D. Bearce. Ry. Rev., vol. 69, No. 1, July 2, 1921, pp. 1–5, 5 figs. Electrification of Paulista railway with American equipment.

3,000-Volt Electrification on Paulista, S. B. Cooper and W. D. Bearce. Elec. Ry. Jl., vol. 57, no. 24, June 11, 1921, pp. 1075–1084, 24 figs. Railway electrification of 28-mile section of double-track main-line of Brazilian railway. Details of Westinghouse and Gen. Elec. locomotives used.

Europe. Railway Electrification in Europe, J. V. Dobson and F. E. Wynne. Elec. Ry. Jl., vol. 57, no. 24, June 11, 1921, pp. 1068–1074, 12 figs. Impressions of present practices and tendencies gathered by writers on trip through England, Norway, Sweden, Germany, Switzerland, Italy and France. Summary of points of difference between American and European railway usage.

High-Tension Direct-Current. Note on the Electrification of French Railways (Note sur l'électrification des réseaux de chemins de fer français), M. A. Ferran. Revue genérâle des Chemins de Fer et des Tramways, vol. 40, no. 5, May 1921, pp. 313–352, 18 figs. Study of electric traction by high-tension direct surrent.

High-Voltage. Railroad Electrification at High Voltage, F. H. Shepard. Ry. Age, vol. 70, no. 25, June 24, 1921, pp. 1441–1444, 6 figs. Development of alternating-current equipment and its relation to power supply.

RAILWAY MAINTENANCE

Organization. On the Question of Maintenance and Supervision of the Track, Chas. J. Brown. Bul. Int. Ry. Assn., vol. 3, No. 6, June 1921, pp. 663–690, 21 figs. Report from railways on their system of organization of staff and their methods of carrying out the work of maintenance of track.

RAILROAD MANAGEMENT

Economies. Possible Economies in Railroad Management, W. Jett Lauck. Indus. Management, vol. 62, no. 1, July 1, 1921, pp. 7–9. Argument on behalf of railroad employees before U. S. R. R. Labor Board.

Legislation, Switzerland. Federal Law Regulating Organization and Management of Federal Railways (Loi fédérale réglant l'organisation et l'administration des chemis de fer fédéraux). Bulletin technique de la Suisse romande, vol. 47, no. 12, June 11, 1921, pp. 136–140. Project of law evolved by Swiss Dept. of Railways and submitted to Federal Chambers in June 1921.

RAILWAY MOTOR CARS

Internal-Combustion-Engines. Railway Motor Coach with Internal Combustion Engine. Engr., vol. 131, no. 3415, June 10, 1921, pp. 612–613, 6 figs. Direct drive by internal-combustion engine. Translated from Génie Civil.

RAILWAY OPERATION

Car Service. The Delaware and Hudson's New Car Service Rules. Ry. Age, vol. 71, no. 2, July 9, 1921, pp. 73–75, 3 figs. Revised rules for promoting prompt car movement simplified for the benefit of yardmasters.

Cost Accounting. Remedies for Wastes in Railway Operation, F. J. Lisman. Ry. Age, vol. 71, no. 2, July 8, 1921, pp. 59–63. Suggestions in regard to cost-keeping methods.

Train Control. The Train Control System for the North British Railway. Ry. Gaz., vol. 34, no. 22, June 3, 1921, pp. 835–846, 20 figs. Total mileage of railway is 1399.

Train Dispatching. On the Question of Slow-Freight Traffic, Mr. Guerber. Bul. Int. Ry. Assn., vol. 3, no. 6, June 1921, pp. 641–662, 4 figs. Report on organization of train service.

RAILWAY SIGNALING

Repetition of Signals on Locomotive. Automatic Stopping of Trains and Repetition of Signals on Locomotives (Arrêt automatique des trains et répétition des signaux sur les locomotives), C. Vandevelde. Annales de l'Association des Ingénieurs sortis des Ecoles speciales de Gand, vol. 11, no. 5, 1921, pp. 45–62. Advantages and disadvantages of automatic brakes. Necessity of developing simple system for reproducing track signals on locomotives.

Interlocking. New Traffic Locking on C. & O. Relieves Congestion, H. E. Johnson. Ry. Age, vol. 71, no. 1, July 2, 1921, pp. 25–26, 3 figs. Interlocking by alternating current of 125 cycles.

RAILWAY TRACK

Standardization of Material. Standardization of Track Material by French Railways (La standardisation du matériel des voies des chemins de fer français). Génie Civil, vol. 78, no. 22, May 28, 1921, pp. 458–459, 7 figs. Profiles and dimensions of three standard rails and corresponding fishplates proposed by engineering committee appointed by Ministry of War.

RAILWAYS

Rolling-Stock Material Specifications. British Standard Specifications for Railway Rolling Stock Material. British Eng. Standards Assn., no. 24, Mar. 1921. Part 1, 27 pp., 7 figs.: Locomotive, carriage and wagon axles. Part 2, 16 pp., 8 figs.: Locomotive, carriage and wagon tires. Part 3, 24 pp., 7 figs.: Laminated, volute and helical springs, and steel for laminated springs. Part 4, 19 pp., 7 figs.: Steel forgings, blooms and castings. Part 6, 28 pp., 17 figs.: Steel plates, angles, etc., and rivets for locomotives, carriages and wagons.

REDUCTION GEARS

Performance. Reduction Gears for Ship Propulsion, Robert Warriner. Mar. Eng., vol. 26, no. 7, July 1921, pp. 532–538, 5 figs. Performance of single and double reduction gears. Comparison with other methods of propulsion. (Abstract.) Paper read before Soc. of Naval Architects and Mar. Engrs.

REFRIGERATING PLANTS

Internal-Combustion Engines for. Internal-Combustion Engines as Prime Movers for Refrigeration Plants, W. H. Motz. Power, vol. 54, no. 2, July 12, 1921, pp. 58–60, 6 figs. Economy of producer-gas-engine plant.

RESEARCH

Foundry. Research in the Foundry, Engineering, vol. 111, no. 2894, June 17, 1921, pp. 749–750. Work recently undertaken by British Government.

Industrial. Research in Industry, L. A. Hawkins. Jl. Soc. of Automotive Engrs., vol 9, no. 1, July 1921, pp. 20–22. Practice of Gen. Elec. Co.

ROLLING MILLS

Sheet Mills. Milwaukee Sheet Mill Has New Features, Gilbert L. Lacher. Iron Age, vol. 107, no. 25, June 23, 1921, pp. 1681–1685, 8 figs. Bar storage and shipping department are under roof.

Western Sheet Mill New Rolling, George H. Manlove. Iron Trade Rev., vol. 68, no. 25, June 23, 1921, pp. 1715–1719, 9 figs. Installation of Milwaukee Rolling Mill Co. built in two units. Balanced roughing rolls are provided. Bar shear equipped with mechanical piler.

ROPE DRIVE

Bollen Cable Pulley. The Bollen Cable Pulley. Engineering, vol. 111, no. 2895, June 24, 1921, p. 771, 6 figs. System built up of two independent wheels and a movable race. When pulley is in operation, pull on cable causes movable race to be forced inward on side at which pressure comes and as a result rims of two wheels close together and grip cable.

RUDDERS

Kitchen Type. The Kitchen Reversible Propeller (Le gouvernail a changement de marche kitchen). Génie Civil, vol. 78, no. 19, May 7, 1921, pp. 396–397, 6 figs. Rudder is surrounded by system of two cylindrical deflectors mounted on common pivots and capable of rotating jointly or separately about rudder.

SCREW MACHINES

Tools. The Calculation of Circular Form Tool Diameters Having Top Rake, A. Washington. Machy. (Lond.), vol. 18, no. 455, June 16, 1921, pp. 337–338, 3 figs. Formulas.

SCREW THREADS

Cutting. The Problem of Accurate Thread Cutting, B. M. W. Hanson. Machy. (N. Y.), vol 27, no. 11, July 1921, pp. 1012–1014, 4 figs. Requirements to fulfill in fitting threaded parts. Work of engineering committees in establishing tolerances within so-called commercial limitations.

SCREWS

Specifications. Report on British Standard Heads for British Association Screws. British Eng. Standards Assn., no. 57, Dec. 1920, 7 pp., 9 figs. Schedule of dimensions of various types of heads for small screws for sizes 0 to 15 B. A. covering range of diameters from 6 mm. to 0.9 mm. (0.236 in. to 0 035 in.).

SEARCHLIGHTS

Advertisement Projector. A New Type of Advertising Searchlight ("Atrax"), H. Geitel. Elektrotechnischer Anzeiger, vol. 38, no. 79, May 19, 1921, pp. 509–516. Details of advertisement projector constructed by the Atrax Co., Berlin, said to have a novel and attractive light effect and to be economical in consumption of power.

Naval Targets. Tactical Organization and Employment of Searchlights against Naval Targets, John S. Pratt. Jl. U. S. Artillery, vol. 54, no. 6, June 1921, pp. 525–567, 24 figs.

SHAFTS

Design. Graphical Determination of Shaft Diameters, N. Barnes Hunt. Machy. (N. Y.), vol. 27, no. 11, July 1921, pp. 1036–1037, 2 figs. Charts for graphically finding proper diameters of shafts subjected to combined tension and torsion. Sizes from 15/16 in. to 5 7/16 in. inclusive.

SHIP PROPULSION

Internal-Combustion Engines. Internal Combustion Engines Applied to Propulsion, John F. Metten and J. C. Shaw. Mar. Eng., vol 26, no. 7, July 1921, pp. 542–545. Comparative earning capacities of motorships and oil-burning steamers. Machinery equipment of motorship William Penn.

Methods. Ship Propulsion, T. C. Phillips. Jl. Eng. Inst. of Canada, vol. 4, no. 7, July 1921, pp. 396–404. Modern methods of ship propulsion, reciprocating engine, steam turbine, internal-combustion engine and electric drive.

SHIP PROPULSION, ELECTRIC

Merchant Marine. Electric Propulsion for Merchant Marine, Wilfred Sykes. Jl. Western Soc. Engrs., vol. 26, no. 6, June 1921, pp. 211–219. Comparative fuel requirements of reciprocating engines, gear turbines, electric drive, direct-connected Diesel engines and Diesel-electric drive.

SHIPS

Refrigerator. Balsa Insulation for Refrigerator Ships. Mar. Eng., vol. 26, no. 7, July 1921, pp. 557–560, 3 figs. Standard insulation plans.

SOLDERS

Soft. War Experience with Soft Solders, Hans Schulz. Metal Industry (Lond.), vol. 18, no 23, June 19, 1921, pp. 443–444. Experiments conducted during war by German Naval Dept. on tin-lead, cadmium, Matulot, Thyssen and magnesium solders.

STACKS

Concrete-Encased. Conservation of Corrosion Weakened Steel Stacks by Encasing with Concrete, John V. Schaefer. Eng. & Contracting, vol. 55, no. 25, June 22, 1921, pp. 619–620, 3 figs. Experience South Works of Ill. Steel Co.

STEAM

Flow in Pipes. Handy Steam Velocity and Steam Flow Tables, V. F. Davis. Mar. Eng., vol. 26, no. 7, July 1921, pp. 522. Capacities of steam pipes in pounds per minute with steam-flow velocity of 6000 ft. per min.

Properties. The Specific Volume of Dry Steam, M. J. Eichhorn. Power, vol. 53, no. 25, June 21, 1921, pp. 1006–1007, 1 fig. Nomogram for specific volume dry steam.

STEAM-ELECTRIC PLANTS

Glasgow, Scotland. The Dalmarnock Power Station. Engineering, vol. 111, nos. 2894 and 2895, June 17 and 24, 1921, pp. 736–738, and 748, 12 figs., and 767–771, 6 figs. June 17: Turbo-alternator, 15,000 kw. capacity. June 24: Electrical equipment.

STEAM ENGINES

25,000-Hp. Three-Cylinder, 25,000-Hp. Steam Engines for Rolling Mill Drive (Machine à vapeur à trois cylinders de 25,000 chevaux pour la commande d'un train de laminoir). Génie Civil, vol. 78, no. 23, June 4, 1921, pp. 469–472, 6 figs. Installation in Middlebrough Steel Works, England.

Uniflow. New Unaflow Engine Design. Power, vol. 53, no. 26, June 28, 1921, pp. 1042–1043, 4 figs. Equipped with high-lift poppet valves of small diameter, which are operated from valve shaft, geared to run at twice speed of main engine shaft.

STEAM ROLLERS

Manufacture. Modern Methods on Steam Roller Construction. Eng. Producton, vol. 11, no. 37, June 16, 1921, pp. 725–729, 13 figs. Interchangeable manufacturing processes at representative works.

STEAM TURBINES

British Thomson-Houston. Recent Improvements in Steam Turbine Design—IV. Engr., vol. 131, no. 3414, June 3, 1921, pp. 592–593 and 596, 8 figs. Recent types manufactured by British Thomson-Houston Co.

Lubrication. Lubrication of Steam Turbines—I. Gen. Elec. Rev., vol. 24, no. 7, July 1921, pp. 651–655. Principles of oil lubrication with special reference to turbine bearings, consideration being given to effects of speed, clearance, cooling by means of oil circulation, viscosity and emulsification.

Parsons. Recent Improvements in Steam Turbine Design—V, C. A. Parsons and Co. Engineer, vol. 131, no. 3416, June 17, 1921, pp. 640–642, 5 figs. Typical installations of Parsons turbines.

Flaws in Straightening. Flaws Resulting in Steel Pieces during Straightening (Les criques de rectification), Léon Guillet, Jean Galibourg and Pierre Beuret. Revue de Métallurgie, vol. 18, no. 4, April 1921, pp. 213–220, 13 figs. Flaws attributed to heating metal under rollers.

High-Speed Steel. Heat-Treatment of High-Speed Steel Cutting Tools of Intricate Design, A. J. Langhammer. Chem. and Met. Eng., vol. 25, no. 1, July 6, 1921, pp. 30, 3 figs. Comparison of various methods

STEEL INDUSTRY

France. The French Iron and Steel Industry. U. S. Dept. of Commerce, Commerce Reports, no. 145, June, 23, 1921, pp. 1709–1715. Statistics of production. Condition of plants and number of workmen.

Prices. The Cause of Industrial Depressions, George Huntington Hull. Indus. Management, vol. 61, no. 11, June 1, 1921, pp. 386–391, 5 figs. Why iron is barometer of trade, and why heavy cut in steel prices is now inevitable.

STEEL MANUFACTURE

Basic Steel. The Behavior of Sulphur in the Thomas Converter (Das Verhalten des Schwefels in der Thomasbirne), E. Herzog. Stahl u. Eisen, vol. 41, no. 23, June 9, 1921, pp. 781–788 and (discussion) pp. 788–789, 2 figs. States that the cooling of pig-iron bath brought about by the addition of lime causes a strong segregation of sulphur in form of sulphide of manganese; in further process of decarbonizing period the sulphur returns to bath in form of sulphide of iron.

Electric Furnaces. Accounting for Electric Alloy and Tool Steel, G. Harvey Porter. Jl. of Accountancy, vol. 32, no. 1, July 1921, pp. 1–15. Tabulation of control accounts, and method of drawing up details of 14 records.

Processes. Development of Iron Ore into Iron and Steel, S. C. Dickerhoff, Jr. Forging & Heat Treating, vol. 7, no. 6, June 1921, pp. 336–337. Chart indicating prices.

STEEL WORKS

England. British Iron and Steel Centers—IV, Joseph Horton. Iron Trade Rev., vol. 68, no. 25, June 23, 1921, pp. 1720–1722, 1 fig. District of South Wales and Monmouthshire.

France. Steel Works at Hagondange, near Metz (Les aciéries Thyssen a Hagondange, prés Metz). Génie Civil, vol. 78, no. 19, May 7, 1921, pp. 393–396, 9 figs. partly on supp. plate.

Power Generation. Power Generation in Steel Mills and Its Relation to Frequency, D. M. Petty. Assn. Iron & Steel Elec. Engrs., vol. 3, no. 6, June 1921, pp. 199–212, 2 figs. Blast-furnace-gas power station. Selection of frequency.

STOKERS

Mechanical. Limitations of Mechanical Stokers. Power Plant Eng., vol. 25, no. 13, July 1, 1921, pp. 674–675. Limitations of mechanical stokers utilizing Mid-West coals.

STRUCTURAL STEEL

Compression Members. Tests with Compression Members (Versuche mit Druckstäben), H. Grüning Bauingenieur, vol. 2, no. 11, June 15, 1921, pp 285–290, 5 figs. Account of two tests carried out by the Steel Construction Testing Committee, showing effect of use of different grades of iron (with varying elasticity) in bar, and also influence of system of articulation.

SUBMARINES

German U-Boats. The Construction of U-Boats in the Germania Shipyard (der Bau von Unter seebooten auf der Germaniawerft), H. Techel. Zeit. des Vereines deutscher Ingenieure, vol. 64, no. 52, Dec. 25, 1920, pp. 1097–1103, 26 figs., 8 on supp. plate. Notes on the first U-boats built in the Germania shipyards; the Forelle, built in 1902 for Russia, three other Russian submarines, the Karp, Karras and Kambala, put in service in 1907, and the first German U-boat, built in 1904. The first U-boats built for the German navy with Diesel engines and the development of this type during the war. (Concluded.)

SUBSTATIONS

Automatic. Automatic Substations Entering Electric Service Field, R. J. Wensley. Elec. World, vol. 78, no. 1, July 2, 1921, pp. 14–15, 4 figs. It is said automatic substation has definitely proved success in industries. Advantages claimed are saving in feeder copper and good service rendered.

Brief Review of Automatic Substation Experience on the Aurora Elgin & Chicago R.R., S. E. Johnson. Gen. Elec. Rev., vol. 24, no. 7, July 1921, pp. 610–612, 1 fig. Inspection periods are seven days apart and control equipment is adjusted to furnish maximum of power throughout 24 hours.

SUPERHEATED STEAM

Steamships. Superheated Steam on Steamships, C. H. Peabody. Mar. Eng., vol. 26, no. 7, July 1921, pp. 539–541, 4 figs. Comparison with locomotive and shore practice. Results with reciprocating engines and Scotch boilers.

SWAGING

Cold. Cold Swaging—II. Machy. (N. Y.), vol. 27, no. 11, July 1921, pp. 1018–1021, 8 figs. Methods employed by Torrington Co., Torrington, Conn., in making swaging dies.

T

TANKS MILITARY

Caterpillar. Caterpillar Vehicles. Automobile Engr. vol. 11, no. 151, June 1921, pp. 198–200, 5 figs. Recent developments of flexible track scheme.

TAR OIL

Creosote Content. The Determination of the Acid Components in Tar Oils, Especially in Low-Temperature-Tar Oils (Ueber die Bestimmung der sauren Bestandteile in Teerölen, insbesondere in Urteerölen), A. Lazar. Chemiker-Zeitung, vol. 45, no. 25, Feb. 26, 1921, pp. 197–199. Improved gravimetric and differential methods for more accurate determination of creosote content in tar oils.

TELEGRAPHY

Multiplex. Multiplex Telegraphy and Telephony on High-Frequency Lines (Multipletelegraphie und -telephonie auf Leitungen mit Hochfrequenz), Karl Willy Wagner. Ingenieur, vol. 36, no. 24, June 11, 1921, pp. 453–464, 34 figs. Account of tests begun in Telegraph Testing Station of Berlin. Experiences with multiplex high-frequency telephone lines between Berlin and Hanover, Berlin and Frankfort, etc. In writer's opinion, high-frequency telegraphy is a much simpler technical problem than ordinary telegraphy. Details of apparatus for operation of the new high-frequency lines.

TERMINALS LOCOMOTIVE

M. K. & T. Ry. New Locomotive Terminal for the M. K. & T. Ry., at Oklahoma City. Ry. Rev., vol. 68, no. 26, June 25, 1921, pp. 959–966, 16 figs. Terminal includes 10-stall roundhouse, machine shop, power plant, water treating plant, reinforced-concrete coaling station, storehouse and track scale built in reclaimed land together with new cut-off line which will obviate necessity for track elevation.

TERMINALS, RAILWAY

Chicago. New Freight Terminal Nearing Completion in Chicago. Ry. Age, vol. 71, no. 2, July 9, 1921, pp. 65–69, 7 figs. Multiple-story construction and elevators are features of Chicago & Alton project.

Unusually Low Maintenance

It was fifteen months after the Stokers were started before any replacements were required at the Parkers Wharf Power Station of the Union Street Rwy. Company, New Bedford, Mass., except for shearing pins. This installation consists of four six-retort stokers firing 500 H. P. boilers and was put in operation during the spring of 1919. Considering the conditions under which a stoker must work, this indicates good operation and sturdy stoker construction.

But you can expect low maintenance from the Riley—it is built for hard service.

The Riley has moving grates; these keep the fire free from holes and the grates evenly covered with coal, preventing burnouts.

The safety shearing pin in the connecting rod of each retort effectively prevents foreign matter from damaging the stoker.

When considering stokers, don't think of the first cost alone, maintenance is an important item.

Send for catalog A-4 and see how the careful design and construction of the Riley Stoker are keeping maintenance to a minimum in the many plants where they are installed.

The Sanford Riley Stoker Co. is now prepared to equip new Riley Stokers with Coal Agitators licensed under the Negus-Tiffany Patents.

Application of the Law of Kinematic Similitude to the Surge-Chamber Problem

By W. F. DURAND,[1] STANFORD UNIVERSITY, CAL.

The problem of the hydraulic surge chamber gives rise to certain differential equations which do not admit of solution in analytical form. Under these conditions, various modes of treatment have been proposed. The present paper develops and describes a comprehensive experimental method utilizing the law of kinematic similitude. By this method a laboratory model of convenient dimensions is set up and subjected to a program of operation corresponding to that for the field installation. The movements of water level, times, etc., as measured for the model, are then multiplied by suitable relation factors, thus giving the results to be anticipated for the field installation.

The model may thus, in a sense, be considered as a form of mechanism which solves the equations as applied to the model form, and these results multiplied by suitable relation factors give the corresponding results to be anticipated in the field case.

The principle advantages of the model method are as follows:

1 The model is simple and readily set up. Once in operation, the most varied conditions may be quickly examined, thus making possible a range of examination in detail, the extent of which would be quite impracticable by any methods of numerical computation.

2 In all analytical methods of treatment, pipe-line friction has been assumed to vary with the square of the velocity. In the model method the friction may be taken to vary with v^n, where n is usually found to be about 1.85.

3 In analytical methods the surge chamber is usually taken as uniform in cross-section. With the model, the chamber may be of any form whatever.

4 The model method is readily extended to the case of a surge chamber with spillway or to the case of multiple chambers on one pipe line.

5 The model method provides readily for the examination of periodic fluctuations in power demand, of any amplitude and any periodicity. The examination of such fluctuating programs is beyond practical reach by numerical methods.

It is assumed in what follows that the general physical phenomena of surges and of surge-chamber operation are familiar to the reader. They have been often described both in textbooks on hydraulics and in special papers on the subject, and to such sources the interested reader may refer for more complete details.[2]

The problem of the surge chamber as a problem on hydraulics gives rise to a pair of simultaneous differential equations as follows:

$$\frac{L}{g}\frac{dv}{dt} = H - y - cv^n \qquad [1]$$

$$\frac{F}{A}\frac{dy}{dt} = v_2 - v \qquad [2]$$

where L = length of conduit
v = velocity
H = head measured from datum at bottom of chamber to level of water in supply reservoir
y = height of water level in surge chamber above datum at bottom of chamber
F = cross-section area of surge chamber
A = cross-section area of conduit
c = factor such that cv^n = sum of friction and velocity heads at velocity v
n = index in expression cv^n and usually found numerically to be about 1.85.

Regarding the factor c in Equation [1] it may be noted that the sum of the velocity and friction heads would usually be represented as the sum of two terms of the form $v^2/2g + bv^m$, where m is the index of variation for frictional resistance with velocity and b is the factor connecting v^m with loss of head due to friction and depending, primarily, on length of line, mean hydraulic radius, and character of surface. It is, however, simpler to combine these two terms into one (the first is in all practical cases relatively small), and it is quite as easy to represent the sum, as derived experimentally, by a single term of the form cv^n as it is for the friction head alone by a term of the form bv^m. In any actual case, furthermore, the values of m and n would be hardly distinguishable. The value of n thus indicated is usually found to be about 1.83 or 1.85. For very rough surfaces it will approach more nearly to 2.

It should be further noted that the actual details of the transition phenomena during the period of change of load and while settling down to new conditions will depend on the character of the governor action during the same period. At least four assumptions may be made regarding the results of such action, as follows:

(*a*) A uniform rate of flow at the amount required for the new power demand under steady flow conditions
(*b*) Constant power output from the wheel
(*c*) Constant power input to the wheel
(*d*) Control valve or gates put immediately into the position corresponding to the final steady flow condition and left unchanged during the transition period.

No one of these assumptions is accurate. If we could assume the load demand to instantaneously change and then remain uniform at the new value and if we could assume the governor capable of exercising perfect and complete control, then it would, under the new conditions, maintain constant speed and hence constant power.

No governor is, however, able to operate in this ideal manner, and the load changes are not usually instantaneous followed by uniformity at the new value. Actually the load may change suddenly, followed by minor variations in settling to something approaching a uniform value. The governor is, furthermore, chasing back and forth with a time lag between speed changes and the actual operation of gate or valve mechanism. Any attempt to include governor action in the equations for the movement of the water in the surge chamber can thus be only partial at the best, and such attempt greatly complicates the resulting equations and their treatment, no matter by what method.

Equations [1] and [2] are based on assumption (*a*), that of a constant-volume flow at the rate which, under steady conditions, would serve to give the power required under the assigned new conditions of power demand, and this assumption results in such a notable simplification in the analytical expressions involved that mathematical discussion of the problem is usually based on the equations in this form.

It does not follow, however, that for the application of the law of similitude this particular assumption is the one best suited to the experimental phase of the problem. As will be shown at a later point, assumption (*d*) is by far the most convenient for experimental realization. However, the determination of the conditions for similitude and of the numerical ratios through which the various relations are expressed is quite independent of the

[1] Professor of Mechanical Engineering, Leland Stanford Junior University. Mem. Am.Soc.M.E.

[2] Trans. Am.Soc.M.E., vol. 34 (1912), p. 319; *Western Engineering*, December 1913.

Presented at the 1921 Spring Meeting of the National Academy of Sciences, Washington, D. C., but published only in brief abstract in the Proceedings.

particular assumption which may be made regarding the results of governor action on the flow conditions during the period of change. Hence, since assumption (*a*) leads to the simplest system of Equations [1] and [2], we may conveniently use these equations for the further development of the general problem, and then at a suitable point return to the question of the consequences to be anticipated from these various assumptions regarding the results of governor action during the period of change.

As treated in the literature of the subject, furthermore, the index n is usually taken as 2. This corresponds in effect to the assumption that friction loss varies as the square of the velocity—an assumption which is well known to be definitely in error. The difficulties of analytical treatment in any form are, however, so vastly increased by the assumption of a value of n such as 1.85, that the value 2 has been commonly accepted for the index of v.

The two equations with the value $n = 2$, when combined, give rise to a differential equation of the second order and second degree and containing both the first and second powers of dy/dt. This equation does not seem to admit of analytical solution, at least in terms of present known functions.

Some years ago the author made brief mention of the possibility of treatment by experimental methods making use of the principles of kinematic similitude,[1] and at a subsequent time[2] a discussion

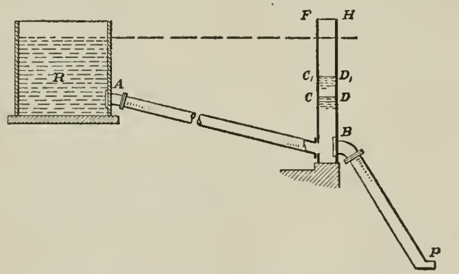

Fig. 1 Diagrammatic Representation of Reservoir, Conduit and Surge Chamber

of the problem was published covering the application of this method to the case with the index $n = 2$.

The present paper aims to generalize this mode of treatment by extension to the case with a general index n, and including likewise the possible case of two or more surge chambers connected to the same line.

It will be evident that if the equations with $n = 2$ do not admit of analytical solution, any such mode of treatment with $n = 1.85$ will be likewise and still more definitely out of the question, and if any general mode of treatment is to be found, it will needs fall under one or the other of two classes: (1) numerical, by the method of numerical quadratures, so-called; or (2) experimental, by the use of a model connected with the actual field case through the principles of kinematic similitude.[2] It is with the latter of these that the present paper deals.

Kinematic Similitude

Before attempting to develop the conditions of kinematic similitude between two cases, it is necessary first to note what is implied by this term.

To develop the idea, let Fig. 1 denote diagrammatically the characteristic elements of a given case. R denotes the reservoir supplying water through the conduit AB to a power plant at P. Let BFH denote a standpipe or surge chamber relatively near to P. Let the plant be running at a steady rate of output with a velocity of flow v_1 in AB. Then, taking the case of demanded load, let there come a sudden demand for more power and consequently more water such as would require, under steady conditions in AB, a velocity v_2. The conditions of flow in AB will, however, not permit of an immediate response. The proximity of the surge chamber

[1] Trans. Am.Soc.M.E., vol. 34 (1912), p. 319.
[2] *Western Engineering*, December 1913.

to the power house does, on the other hand, permit of prompt or sensibly immediate response and accordingly the additional amount of water required to make up the supply to the wheel, corresponding to a velocity v_2 in AB, is drawn from BFH. In consequence the level in BFH falls, occupying at a given instant of time immediately after the new power demand, some level such as CD, while the level for steady-flow conditions still remains sensibly at C_1D_1. This difference of level, the actual level lying below that for steady conditions, means the development of an accelerating head measured by the difference between these two levels. In response to this accelerating head, the velocity of flow in AB will begin to increase and such increase will continue so long as the accelerating head remains operative—that is, so long as the actual level lies below that for steady-motion conditions. In consequence the velocity v will pass gradually through a series of values on the way from v_1, the initial value, to v_2, the final value. In general, during this period the actual level will lie below the level for steady conditions with the actual velocity v, thus constituting a continuing accelerating head and in answer to which the water in AB undergoes a corresponding positive acceleration. If the conditions should be such as to bring about a gradual decrease of this accelerating head as the velocity approaches the value v_2, ultimately vanishing when $v = v_2$, then the series of transition phenomena comes to an end with this condition, and the water level remains at its new location with velocity v_2. Actually, however, these conditions are not fulfilled. When the velocity first reaches v_2 the acceleration head is still positive; that is, the actual level is below that for steady conditions with velocity v_2, and in consequence the velocity is carried on to some value greater than v_2 until finally the two levels do come together, but with a velocity $v > v_2$. This means more water is coming along AB than is required at the power plant, and in consequence the excess will be received by the surge chamber and the actual level of the water will rise above its location for steady-flow conditions, thus producing a *retarding* head and gradually reducing the velocity v from its maximum value back toward v_2 again. On reaching v_2, however, the actual level will still lie above that for steady-flow conditions, a corresponding retarding head will still be operative and the velocity will be carried beyond and below v_2 until the retarding head vanishes and becomes replaced by an accelerating head, when the velocity is again carried upward toward the value v_2. In this way there will be an indefinite number of oscillations of level about the final location and a corresponding indefinite series of oscillations of value of the accelerating head from positive to negative and back again, and a corresponding series of fluctuations of velocity above and below v_2—all of these oscillations and fluctuations of continuously diminishing amplitude, until finally they all sensibly die out together with the velocity at v_2 and the water level at the corresponding location for steady conditions.

In the case of rejected load and a sudden excess of water flowing in AB, with v_2 less than v_1 the excess water will be received by the surge chamber and will result in a rise in the actual level above that for steady-flow conditions, thus producing a retarding head. In answer to this, the velocity will become gradually *reduced* from v_1 toward v_2, passing through a series of fluctuations, with corresponding oscillations in the water level, in manner entirely similar to that for demanded load.

It will then be evident that if we should represent graphically on a time axis the essential phenomena which characterize this transition period, we should have curves as follows:

1 A time history of the movement of the actual water level CD
2 A time history of the movement of the level for steady conditions with the actual velocity v
3 A time history of the difference of these two levels, constituting in general (for demanded load) an accelerating head, and measured by the left-hand member of Equation [1]
4 A time history of the velocity v as it passes through periodic fluctuations from the initial value v_1 to the ultimate value v_2.

Suppose such a group of curves for the first part of the transition period be as represented in Fig. 2. Let us designate the physical system to which these curves correspond as system A. Now let us imagine a system B, comprising the same elements, but different

in size and proportion, and so related to A as to fulfill the following conditions:

For any time t on system A there will be a corresponding value of any one of the four characteristics above noted. Then for system B, let there be a time αt for which the value of the same characteristic will be related to the value for system A by a ratio β and where α and β are constant factors. This would mean that if curves for system B were run out similar to those for system A, then the two sets of curves would be geometrically similar, being related along the axis of abscissæ by the ratio α and along the axis of ordinates by the ratio β. It would mean, furthermore, that if the two sets of curves were plotted with suitable scale units, related for t in the relation of 1 to α and for any one of the four characteristics in the relation of 1 to the corresponding β, the two curves would become coincident. It will, of course, be understood that there will be one value of α for the time relation and two

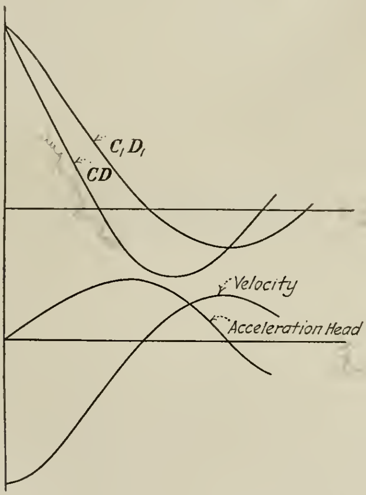

Fig. 2 Curves Representing Essential Phenomena Characterizing First Part of Transition Period

values of β, one for the three vertical dimensions or movements and one for the velocity v.

Now two systems A and B fulfilling the conditions thus indicated are said to have kinematic similitude.

It is then clear, if B, let us say, is a field case and A is of laboratory dimensions and if we can determine the coefficients α and β, that experimental observation on A will serve to determine through α and β the results to be anticipated for B.

We must next inquire as to the conditions for realizing such relation of kinematic similitude. Let us first assume that it *is* realized and by way of notation let:

p = ratio of conduit lengths = L ratio
q = ratio of the two values of c = c ratio
r = ratio of velocities = v ratio
s = ratio of the times = t ratio

Now referring to Equation [1], it has been stated (without present proof) that the expression $(L/g)(dv/dt)$ is the measure of an accelerating head; that is, the measure of the head required to produce the acceleration dv/dt. This head is, of course, a vertical dimension. Now since Equation [1] is a physical equation, it must be homogeneous in all its terms. That is, all terms must represent vertical dimensions. In fact, it is readily seen that the right-hand side of the equation is composed of members, each one of which is a vertical dimension, and the algebraic combination of which is a measure of the difference between two water levels such as CD and C_1D_1, Fig. 1, and which (as previously stated) constitutes the accelerating head.

Now suppose two such equations, one relating to system A and one to system B. Then if the conditions of similitude are fulfilled, there will subsist between the numerical values of the corresponding terms of these two equations, a constant ratio—that corresponding to vertical dimensions or vertical movements. This means specifically that the terms $(L/g)(dv/dt)$, H, y, cv^n, all represent vertical distances or movements, and that between them all, for systems A and B, there subsists the one constant ratio. If, therefore, we can determine this ratio for one, we have it for all. But with the notation assumed above, we have immediately:

$$v^n \text{ ratio} = r^n$$
$$cv^n \text{ ratio} = qr^n$$

Hence we shall have for all vertical dimensions or movements the ratio qr^n. We may denote this in general as the y ratio and have, therefore:

$$y \text{ ratio} = qr^n$$

Then since, in Equation [1], this ratio qr^n applies to each term individually, it must apply to the first term. Hence we may write:

$$\frac{L}{g}\frac{dv}{dt} \text{ ratio} = qr^n$$

But the L ratio = p, the dv ratio must equal the v ratio which is r, and the dt ratio must equal the time ratio which is s. Hence we have:

$$\frac{pr}{s} = qr^n$$

or

$$s = \frac{pr}{qr^n} = \frac{pr}{y \text{ ratio}} = \frac{p}{qr^{n-1}}$$

Again, in Equation [2], if the conditions of similitude are fullfilled, the ratio r will apply to each term individually. It must therefore apply to the first term and we may write:

$$\frac{F}{A}\frac{dy}{dt} \text{ ratio} = r$$

But the dy ratio must equal the y ratio and the dt ratio the t ratio. Hence we have:

$$\left(\frac{F}{A} \text{ ratio}\right)\left(\frac{qr^n}{s}\right) = r$$

or

$$\frac{F}{A} \text{ ratio} = \frac{rs}{y \text{ ratio}} = \frac{pr^2}{(y \text{ ratio})^2} = \frac{p}{q^2r^{2n-2}}$$

Now collecting these various ratios we have as follows:

$$L \text{ ratio} = p \quad\ldots\ldots\ldots\ldots[3]$$
$$c \text{ ratio} = q \quad\ldots\ldots\ldots\ldots[4]$$
$$v \text{ ratio} = r \quad\ldots\ldots\ldots\ldots[5]$$
$$H,y \text{ ratio} = qr^n \quad\ldots\ldots\ldots\ldots[6]$$
$$t \text{ ratio} = s = \frac{pr}{y \text{ ratio}} = \frac{p}{qr^{n-1}}\ldots\ldots\ldots\ldots[7]$$
$$\frac{F}{A} \text{ ratio} = \frac{rs}{y \text{ ratio}} = \frac{pr^2}{(y \text{ ratio})^2} = \frac{p}{q^2r^{2n-2}}\ldots\ldots\ldots\ldots[8]$$

and to which we may add:

$$F \text{ ratio} = (A \text{ ratio})\frac{pr^2}{(y \text{ ratio})^2} \text{ or } (A \text{ ratio})\frac{p}{q^2r^{2n-2}}\ldots\ldots[9]$$

or

$$D \text{ ratio} = (d \text{ ratio})\frac{p^{1/2}r}{y \text{ ratio}} \text{ or } (d \text{ ratio})\frac{p^{1/2}}{qr^{n-1}}\ldots\ldots\ldots[10]$$

$$V \text{ ratio} = (F \text{ ratio})(y \text{ ratio}) = (A \text{ ratio})\frac{pr^{2-n}}{q}\ldots\ldots[11]$$

where D = diameter of surge chamber (assumed circular)
d = diameter of conduit line (assumed circular)
V = volume movement in surge chamber.

We have thus assumed the existence of various structural ratios, of a velocity ratio and of a time ratio, and have derived the relations among these ratios necessary in order that the conditions of homogeneity among the terms of any one equation may be realized.

Suppose now the two systems A and B set up in accordance with these various structural relations. It is then readily seen that we may choose initial conditions of operation which will fulfill

the required relations throughout. That is, at the initial conditions, the requirements for kinematic similitude may be fulfilled by arbitrary adjustment. It is then readily shown that under these conditions the increments of y and v will likewise fulfill the relations for similitude, and hence the succession of values of y and v throughout the entire period of transition.

It thus results with two such systems A and B, with structural relations as specified and for which the water movements are in accordance with Equations [1] and [2], that if the conditions of similitude are fulfilled at the beginning of the movement, they will likewise be fulfilled for subsequent times throughout the movement and thus the general conditions for similitude will be realized as assumed.

Form of Relations for Similitude when $n = 2$

It will next be of interest to note the form taken by these relations if the index n is taken equal to 2, as in the more common methods of treatment of the problem. Referring to [6]–[11], we shall have—

$$y \text{ ratio} = qr^2$$

$$\text{Time ratio } s = \frac{p}{qr}$$

$$\frac{F}{A} \text{ ratio} = \frac{p}{q^2r^2}$$

$$F \text{ ratio} = (A \text{ ratio}) \frac{p}{q^2r^2}$$

$$D \text{ ratio} = (d \text{ ratio}) \frac{p^{1/2}}{qr}$$

$$V \text{ ratio} = (A \text{ ratio}) \frac{p}{q}$$

Surge Chamber with Spillway

A case possessing both interest and importance is presented by a surge chamber fitted with an overflow weir or spillway at a certain fixed height.

Let B = length of such spillway or weir

y_0 = height from datum to level of spillway edge

y = height from datum to surface of water

Then $y - y_0$ = depth of water on weir.

In time dt let the water level rise dy

In time dt the flow along conduit line $= vAdt$

In time dt the discharge over the weir $= QB\,(y - y_0)^{3/2}\,dt$

In this formula for weir discharge Q is taken as containing all factors other than B and $(y - y_0)$

We have then—

$$vAdt = Fdy + QB\,(y - y_0)^{3/2}\,dt \quad \text{[12]}$$

or

$$vA = F\frac{dy}{dt} + QB\,(y - y_0)^{3/2} \quad \text{[13]}$$

This equation together with [1] for the acceleration head will serve instead of [2] to determine the motion of the water level after the water reaches and rises above the weir edge.

To apply the principles of similitude to this case we must assume the weir coefficient Q the same for both weirs, field case and experimental set-up. We then note that each term of [13] is a quantity of the order of volume flow. Hence for similitude we must have the same ratio between the two systems A and B for each member of the equation. Thus we have:

$$vA \text{ ratio} = r\,(A \text{ ratio})$$

$$F\frac{dy}{dt} \text{ ratio} = F \text{ ratio} \times y \text{ ratio} \div t \text{ ratio}$$

or reducing,

$$F\frac{dy}{dt} \text{ ratio} = r(A \text{ ratio})$$

whence

$$[QB\,(y - y_0)^{3/2}] \text{ ratio} = r\,(A \text{ ratio})$$

and

$$B \text{ ratio} = \frac{r\,(A \text{ ratio})}{(y \text{ ratio})^{3/2}} = \frac{A \text{ ratio}}{q^{3/2}r^{3/2n-1}} \quad \text{[14]}$$

If in this case we assume the index $n = 2$ we shall have—

$$B \text{ ratio} = \frac{A \text{ ratio}}{q^{3/2}r^2} = \frac{A \text{ ratio}}{q^{1/2}(y \text{ ratio})} \quad \text{[15]}$$

The volume of water discharged over the weir will be given by the expression—

$$V = QB \int (y - y_0)^{3/2}\,dt \quad \text{[16]}$$

We have then—

V ratio = product of individual ratios for expressions making up V as in [16] hence—

$$V \text{ ratio} = \frac{A \text{ ratio}}{q^{3/2}r^{3/2n-1}}\,q^{3/2}r^{3n/2}\,\frac{p}{qr^{n-1}} = (A \text{ ratio})\,\frac{pr^{2-n}}{q}$$

and for $r = 2$,

$$V \text{ ratio} = (A \text{ ratio})\,\frac{p}{q}$$

This is seen to be the same as the volume ratio for change of volume in the surge chamber, as indeed it should be.

Case with Multiple Surge Chambers

The case with two surge chambers is indicated in Fig. 3 as a

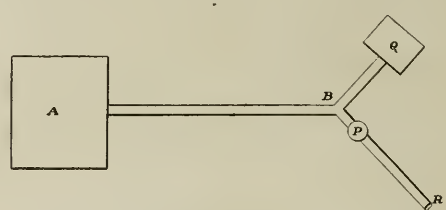

Fig. 3 Diagram of the Case of Two Surge Chambers

plan view. The main supply reservoir is at A, a small regulating reservoir at Q and a surge chamber of usual dimensions at P with the power plant lying beyond at R. With such an arrangement the reservoir Q functions as a large surge chamber, thus complicating the problem as affecting the movement of water in P.

With this combination of elements a disturbance from the conditions of steady flow involves, physically, the problem of three superimposed oscillatory systems; one by way of ABQ, one by way of ABP and one by way of PBQ. To define these conditions, six equations are required as follows:

$$\text{Motion in } AB, \quad \frac{L_1}{g}\frac{dv_1}{dt} = H - z - c_1v_1^n$$

$$\text{Motion in } BP, \quad \frac{L_2}{g}\frac{dv_2}{dt} = z - y_2 - c_2v_2^n$$

$$\text{Motion in } BQ, \quad \frac{L_3}{g}\frac{dv_3}{dt} = z - y_3 - c_3v_3^n$$

$$\text{Continuity at } B, \quad A_1v_1 - A_3v_3 = A_2v_2$$

$$\text{Continuity at } P, \quad A_2v_2 - F_2\frac{dy_2}{dt} = A_1u$$

$$\text{Continuity at } Q, \quad + F_3\frac{dy_3}{dt} = A_3v_3$$

where L_1, v_1, A_1, c_1 = respectively length, velocity, area and coefficient c for AB

L_2, v_2, A_2, c_2 = respectively length, velocity, area and coefficient c for BP

L_3, v_3, A_3, c_3 = respectively length, velocity, area and coefficient c for BQ

H = total static head from top of reservoir at A to datum at bottom of P

z = pressure head at junction B measured from datum at bottom of P

y_2 = level of water in P measured from datum at bottom of P

y_3 = level of water in Q measured from datum at bottom of P

u = velocity in AB corresponds to new demand in R.

In these equations as written, the positive directions of flow are taken as AB, BQ, BP.

Equations of this character and number are quite beyond the range of any practicable mode of mathematical attack, even by way of numerical integration. The methods by way of similitude hold, however, as with the simpler cases, and the model once set up, any condition of operation is readily examined. In setting up the model it is only necessary to use a uniform ratio of length and of diameter or area of conduit. These ratios together with the velocity ratio will then fix the ratio for all vertical distances for time and for the cross-section area of surge chamber.

For a case with more than two chambers the same general principles hold, and any such case may be examined by experimental methods through the use of a model set up with ratios as above. Such cases, however, are not likely to be met with in practice.

For the case of Johnson's differential regulator[1] the same fundamental equations, with suitable interpretation, apply as for the plain open chamber, and under these conditions the ratios and relations will be the same and the performance in detail may be investigated by means of the model method.

Special Notes on Application of Method

In the application of these methods it should be noted that the assumption of a uniform value of the ratio q does not imply the assumption of the same values of friction coefficient for large and for small pipe. It simply implies that for the large pipe the velocity-friction head may be put in the form cv^n, the value of c being constant over the range of velocity involved, and likewise that the similar head for the small pipe may be expressed in the same form, this value of c likewise being constant over the velocity range involved. The ratio between the two values of c will then be the constant q of the formulas.

Also it should be noted that in cases of design the c for the field case will usually be the subject of estimate based on judgment. This, however, is required for any computations or estimates regarding velocity of flow, capacity of line, power, etc., and the one estimate as to friction head will serve uniformly for these varied purposes. On the other hand, the value of c for the experimental model is a matter of direct measurement and in all cases should be so determined. A series of simple measurements of flow, time and drop in level between reservoir and surge chamber will serve as a basis for this determination for the model. Such observations plotted on logarithmic paper provide then a ready means for the determination of the values of c and n for the model, and this value of c compared with the assumed c (with the same n) for the field case will give the value of q as noted above.

Surge Chamber Non-Uniform in Cross-Section Area. It should be especially noted that with the experimental method, the surge chamber is not necessarily of uniform cross-section area. It may be tapering or of any form at will, so long as the model is made of corresponding dimensions. It should also be noted that the ratios of horizontal and of vertical dimensions are not in general the same. The result will therefore be geometrical similarity between the model and full-sized installation, but not the same proportions between horizontal and vertical dimensions.

It is simply necessary that, at corresponding vertical dimensions as determined by one ratio, the horizontal dimensions are also similar, as determined by the other ratio. This is further illustrated by Fig. 4 showing the relative proportions for a full-sized and a model surge chamber, the former as installed on the line of the Los Angles Aqueduct Power System.

Governor Action. At an earlier point in the paper, reference has been made to the various assumptions which may be made regarding the results of governor action during the period of change and to the fact that no assumption which can be made in precise terms will represent the real program in an actual case. Due to the relative simplicity of the equations resulting, however, assumption (a) was implied in deriving the basic Equations [1] and [2].

It should again be especially noted that no matter which of these assumptions may be made, the ratios for similitude remain unchanged. Equations of the type of [1] remain the same, while equations of the type of [2] remain the same in form with the substitution for v_2 of a velocity u in AB, suited to the particular assumptions made.

With (a), v_2 as already noted is the velocity in AB necessary to give, under final steady-flow conditions, the power required under the changed conditions.

With (b), for v_2 we must substitute a velocity u defined as the velocity in AB which would bring the water required to meet the new power requirements under the momentarily changing values of available head and the efficiency of the wheel.

With (c), the velocity u is defined the same as in (b), with the omission of the influence due to variation in efficiency of wheel.

With (d), the velocity u is defined as that corresponding to the total flow through the valve, set as specified, and with the momentarily changing value of the available head as affected by the changing level in the surge chamber.

In all of these cases the term v_2 or u is a velocity and the ratios for similitude remain the same, being unaffected by these various assumptions.

It therefore becomes a question of interest as to which of these four assumptions can be most easily realized in the manipulation of a model.

It is readily seen that assumption (d) most readily meets the requirements. For any specified power development it is a simple

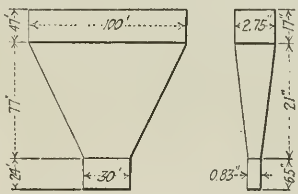

Fig. 4 Relative Proportions for a Full-Sized and Model Surge Chamber

matter to determine the volume flow required under the head corresponding to such flow. To realize the corresponding condition with the model requires simply the setting of a control valve at P, Fig. 1, in accordance with a previously determined calibration.

On the other hand, if any of the other assumptions is to be fulfilled by model, the rates of volume flow corresponding to the special conditions must be determined and the setting of the control valve determined therefrom, taking into account the height of the water in the surge chamber. The valve setting will thus depend on such height and hence the valve will require adjustment continuously during the period of transition, corresponding to the rise and fall of the water in the surge chamber.

As a manipulative program it is entirely possible to realize this through the use of a cam form of control, the movement of the cam being determined in step with the movement of the water in the chamber. Such a program of control is, however, somewhat complex in character and adds in marked degree to the time required for making and assembling the model equipment.

In order, therefore, to realize in the highest degree the advantages of the model method, it is desirable to accept assumption (d) as representing with a sufficient degree of approximation the operative conditions of the plant. An examination of the conditions of operation of a power plant will serve to show, furthermore, that with supposition (d) as compared with either (a), (b) or (c), the resulting conditions as regards surge are more severe and hence that the error will be on the side of safety. It is also evident that the influence of the variation of level of the water in the surge chamber on the general program of volume discharge or of power developed at the power house will be relatively small as the range of such fluctuation is small compared with the difference in level between water in surge chamber and power house and relatively large in the inverse case.

The whole question of the use of a model for the study of such problems turns therefore largely on the degree of closeness to which the manipulation of the model may be made to represent the proposed programs of change in the field installation, and more specifically in the actual power plant; or again on the extent to which the simple model program as indicated in asumption (d) may be

[1] Trans. Am.Soc.M.E., vol. 30, p. 457.

accepted as satisfactory for the purposes in view. As indicated above, it appears that, in all cases where the range of fluctuation of the water level in the surge chamber is small compared with the difference in level between surge chamber and power house, the simple program of (*d*) may be accepted as satisfactory for all practical purposes. If such fluctuation should, on the contrary, be large, the use of the model would presumably require such further devices as would make possible a closer approximation of the program of water flow in the model outlet to the actual or proposed program in the power house.

A further point should be here noted, and that is that the model proper in its correspondence with the field case covers only the main supply line and the surge chamber. It does not necessarily extend to the line from the surge chamber to power house. In the model the line from surge chamber to discharge valve may be considered simply as a means for realizing a desired discharge through the setting of a calibrated valve. From this view, therefore, it is simply necessary to have such size of line and such head as shall insure, through the discharge valve, the rates of flow covering the ranges contemplated. At the same time it is generally desirable to give to this discharge line a vertical dimension not widely dissimilar from that corresponding to the field case, in order that the range of fluctuation of the level in the surge chamber may bear to the difference in level between the surge chamber and power plant approximately the same ratio in both model and field cases.

Special Programs of Change. In addition to the usual problem as presented by a sudden change in power demand followed by substantially uniform conditions, the model method readily serves for the examination of two types of problem, neither of which is practically susceptible of treatment through computation methods. These are as follows:

1 Required the cumulative result of periodic changes of any specified magnitude and with any specified frequency. Thus for illustration, we might have a proposed program of additions to the load, each of 10 per cent total load, and with specified intervals. If the latter should be such as to bring the load changes into approximate synchronism with the surge-chamber movements, the cumulative results might become very serious; while otherwise the resultant movement would be relatively small. Again, we might have the condition of a surging load, alternate increase and decrease and with any proposed frequency. This again, if in approximate synchronism with the surge-chamber movements, may result in the most extreme and serious conditions in the latter.

All such problems are most readily examined by the model. It becomes necessary simply to determine the change of flow corresponding to the proposed change in power and to note the corresponding settings of the control valve. Then with the corresponding time interval known, it is simply a matter of manipulative procedure of the control valve, with corresponding note of the resultant movement of the water in the surge chamber. In this general manner the results of all forms of varied or periodic programs of change in power demand, or of flow in general, are readily examined.

2 Required the time over which a specified power change should be extended in order that the resultant surge-chamber movement may not exceed a specified amount. Thus with a proposed size of surge chamber in a given case, a sudden change of 80 per cent or of 100 per cent of the load, for example, will perhaps produce a surge-chamber movement resulting in extreme overflow at top, or in the indraft of air at the bottom. In either case it may be desired to determine the necessary duration of a specified load change in order that the surge-chamber movement may not exceed specified limits. As a manipulative program this calls simply for the movement of the control valve between specified stops gradually at an approximately uniform rate and involving such total time interval as will meet the requirements within the surge chamber. Experience of the writer shows that this is readily realized by successive trials, and that, as a problem in manipulation, it presents no serious difficulties whatever. The time interval for the model, thus determined, is then to be multiplied by the time ratio, thus giving the required time for the field installation.

Experimental Detail. The experimental program, in general, connected with an investigation of this character is simple and may safely be left to the initiative of the interested reader. A few suggestions on particular points may, however, be acceptable.

The control valve is preferably of the cone or needle type with long taper, so that a considerable stem movement will be required between closed and full open. The stem may be controlled by hand lever or otherwise as most convenient, with, in any case, an index moving over a graduated scale. The valve may then be calibrated for steady-motion discharge or velocity by simultaneous observations of valve setting and weight of water discharged in a given time. Observation of the height of water in the surge chamber for each of these settings furnishes likewise data for a series of values of the friction-velocity head, cv^n, for the model. A carefully drawn curve between discharge and cv^n will then furnish a ready means of determining discharge by a reading of water level in the surge chamber. From this point on, the valve settings should be used simply to realize approximately the conditions desired, the actual velocity or discharge being taken as that corresponding to the water level in the surge chamber under steady flow conditions.

For reading the movement of the water in the surge chamber, either a float with stem or a gage glass on the side may be employed. With the latter there is time lag and some correction may be required. The author has found the former method the preferable The stem may be furnished with an index moving in front of a suitable scale and with all usual proportions the movement is slow enough to readily permit the reading of maximum and minimum points.

Illustrative Problems

I—Suppose an actual case characterized by the following data:

Length of conduit, ft	20,000
Diameter of conduit (assumed circular), ft	10
Upper velocity, ft. per sec	10
Friction-velocity head at 10 ft. per sec. velocity (assumed), ft	50
Proposed diameter of surge chamber, ft	36

Suppose now that we propose to use for the model conduit 50 ft. of pipe 2 in. in diameter and that we select arbitrarily a velocity ratio of 2.5. Suppose further that with this pipe set up we find experimentally $n = 1.85$ and $c = 0.1695$.

Then assuming the same value of n, we find for the field case $c = 0.706$. We have then—

$p = 20{,}000 \div 50$	$= 400$
$q = 0.706 \div 0.1695$	$= 4.17$
r	$= 2.5$
r^n	$= 5.45$
y ratio	$= 22.72$
t ratio	$= 44.0$
D ratio	$= 132.0$
$D = 432 \div 132$	$= 3.27$ in.

If then we set up the model in accordance with these dimensions, we have only to carry out the program of velocity change corresponding to the proposed field program, observe vertical movements and times, multiply the former by 22.72 and the latter by 44.0 and we shall have the vertical movements and times to be anticipated in the field case.

II—Suppose that it is proposed to fit the actual chamber with a spillway 10 ft. wide with edge 6 ft. above static level in supply reservoir. What will be the width and location of the model spillway?

The edge will be located at a height above static level in the supply reservoir measured by $6 \times 12 \div 22.72 = 3.17$ in. The width ratio from [14] is 82.9, hence the width is $10 \times 12 \div 82.9 = 1.45$ in.

III—As a further example drawn from actual practice, reference may be made to Fig. 2 with dimensions as follows:

$$AB = 14{,}000\,f \qquad d_1 = 11.25\,f \qquad d_3 = 11.25\,f$$
$$BQ = 1{,}191\,f \qquad d_2 = 10.10\,f \qquad D = 35.00\,f$$
$$BP = 137\,f$$

where d, d_2, and d_3 refer respectively to AB, BQ and BP.

The area of Q varied with elevation from 120,000 to 150,000 sq. ft., constituting a small regulating reservoir. The following proportions and dimensions were taken for the model:

$$p = 240 \qquad \text{also } d_1 = 1.5 \text{ in.}$$
$$\text{hence } AB = 58.23\,f \qquad d_2 = 1.342 \text{ in.}$$

$BQ = 4.96 f$ $d_3 = 1.5$ in.
$BP = 0.57 f$ $r = 3$

By experiment c and n for the model were found to be 0.195 and 1.823.

By estimate, for the field case, c with the same value of n was taken as 0.421.

This gives $q = 2.16$ and y ratio $= qr^n = 16.00$.

We then find from the proper formulas—

$$t \text{ ratio} = 45$$
$$F \text{ ratio} = 68{,}200$$

This gives F for model = 2.04 sq. in. which corresponds to a circular chamber of diameter 1.60 in.

The same F ratio determines also the model reservoir. This was made as a wooden box with sloping sides, so adjusted as to give, over the possible range of change of level, the proper values of surface area.

The pipe of equivalent diameter 1.342 in. was made by filling in a segment of a 1.5-in. pipe to a point giving the proper area.

This combination of elements, with a suitable discharge valve, completed the set-up of the model. The investigation made possible by this model covered the entire range of flow from closure up to the full flow of 1000 sec-ft. and in both directions, demanded and rejected load. These results are shown graphically in Figs. 5 and 6. Fig. 5 relates to the combination of surge chamber and reservoir, while Fig. 6 refers to the surge chamber in operation alone, the reservoir being shut off.

For the conditions of Fig. 5 the diagram shows the maximum water movement (for the field installation) for the first swing following any sudden change of load in either direction. The vertical scale gives elevation in feet, and the horizontal scale flow of water in second-feet.

The heavy-line curve shows the level of water for steady con-

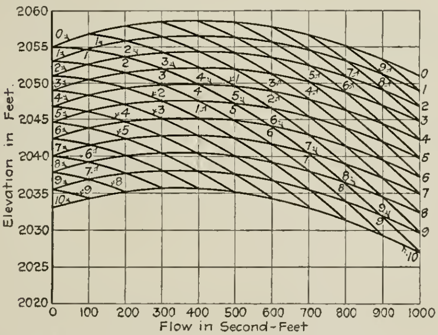

Fig. 5 Flow to be Anticipated with Sudden Change in Either Direction from Any Initial Load V_1 to Any Final Load V_2
(Surge chamber in combination with auxiliary reservoir.)

ditions for flow varying from 0 to 1000 sec-ft. The diagram shows two sets of curves:

1 Curves running clear across the sheet from left to right and crossing the heavy-line curve.

2 Curves approximately parallel to the heavy-line curve and trending, therefore, downward to the right.

Any problem involves two values of the flow—the initial flow V_1 and the final flow V_2.

To determine the surge movement for demanded load, go to point V_1 on the heavy curve and drop vertically to that curve of set 1 which cuts the heavy curve at V_2. The point thus indicated will give the water level for the first surge. If V_2 falls between the curves as plotted, the interpolated value is easily read.

Or again, with the plant in operation under flow V_1, let there be a sudden demand for an *additional* flow V. In this case we may find $V_2 = V_1 + V$ and proceed as above, or otherwise we may go to V_1 on the heavy curve and then drop vertically to that curve of set 2 corresponding to the additional flow V. The point thus indicated will give the extreme level reached.

In the case of rejected load, the operation is entirely similar except that the curves lying to the right and above the heavy line are to be employed.

In Fig. 6 for the surge chamber alone, the manner of plotting and method of use are the same as for Fig. 5.

These diagrams thus give graphically the results to be anticipated with a sudden change in either direction from any initial load V_1 to any final load V_2 and for the surge chamber either alone or in combination with the auxiliary reservoir. The influence of the latter in reducing the extent of the surge is thus brought out in a striking manner.

It is perhaps unnecessary to add that the numerical work re-

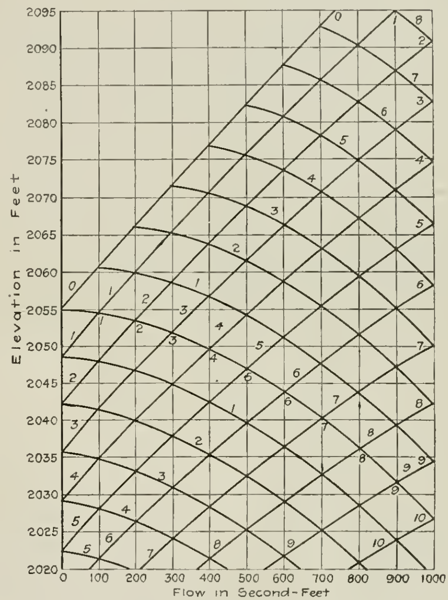

Fig. 6 Flow to be Anticipated with Sudden Change in Either Direction from Any Initial Load V_1 to Any Final Load V_2
(Surge chamber alone.)

quired to derive corresponding results from the six different equations applying to this case would be entirely prohibitive from a practical viewpoint, and if any investigation is to be made of a case of this character, the experimental model method, using the law of kinematic similitude, as herein set forth, seems to be the only recourse available.

A 68,750-hp. hydroelectric plant has been installed on the west coast of India by the Tata Hydro-Electric Power Supply Company. Each of the five main Pelton-type turbines comprising the initial installation has a capacity of 13,750 hp. The head is approximately 1700 ft. and the speed 300 r.p.m. The generators, which are direct-connected, are rated at 10,000 kva. and operate at 50 cycles, 6000 volts, three-phase. On account of the climate the extremely high average air temperature of 113 deg. fahr. had to be allowed for in the generator design, so that the 10,000-kva. units installed would, it is estimated, be capable of delivering 16,000 kva. in a more temperate climate. In spite of this condition, however, the generators are said to have shown an efficiency of 95.8 per cent. The long dry spells make water storage necessary, and three large lakes have been made at an elevation of about 1700 ft. above sea level. Power will be delivered at 100,000 volts over a 239-mile line to Bombay, where a large part of it will be used in the cotton mills there. The tailwater will be diverted into canals and will be used for irrigation purposes during the dry season.—*Power*, September 6, 1921.

Requirements in the Design of Steam Power Stations for Hydraulic Relay

The Flow or Head Deficiency Type of Relay—Effect of Growth of Load, Seasonal Variation of Flow and Pondage—Relay Stations for Minimum Flow Development and for Higher-Load-Factor Conditions—The Emergency Reserve Type of Relay

By E. B. Powell,[1] Boston, Mass.

SUPPLEMENTAL power in some form is an essential to the commercial development of our remaining unused eastern water powers and, with the possible exception of the Niagara-St. Lawrence system, an essential to the further development of such of these water powers as are now utilized in part. The nature and extent of this supplemental, or relay, power will be governed in a large measure by the character of the stream and the amount, character and location of the load and the importance of continuity in power supply.

In many instances the required relay, at least sufficient for the initial development, may advantageously be provided in the stream itself by adding reservoirs, or merely pondage, to give some artificial control of the flow. In other instances the electrical interconnection of water-power systems, so pooling the water resources of dissimilar streams, may also afford sufficient initial relay in hydraulic power. In general, however, the fullest commercial utilization of water power can only be had by the aid of independent

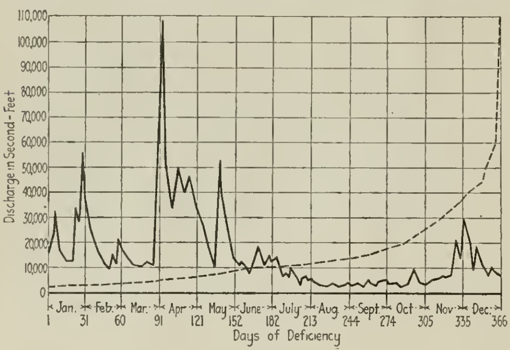

Fig. 1 Daily Hydrograph and Deficiency Curve for 1916, Hudson River at Troy Dam, New York

relay, which in the greater part of the country today is most satisfactorily and economically provided in the steam power station.

The capacity and design of such a relay station should be decided as closely as may be by the particular functions it is intended to perform. The functions of the relay, while they may vary widely, are of two general types, flow or head deficiency make-up and emergency reserve, the second being supplemental to the first. For either type of service the capacity required in any particular case will depend upon the amount and characteristics, initial and prospective, both of hydraulic development and of load. The design, while broadly determined by the usual factors, such as location, power market, water and fuel supplies, fuel costs, which control in the case of the independent central station, is in general, on account of the commonly low load factor, less dependent upon considerations of operating economy. On the other hand, character of load and dependability of delivered hydraulic power are factors of prime importance and, for proper realization of the economic possibilities of the development as a whole, the design should also be governed in many important features by the characteristics of the hydraulic development and the relation of that development to the load.

The Flow or Head Deficiency Type of Relay

Considering first the station intended solely to make up the power deficiencies of the hydraulic development, its functions may include any one or more of the following: seasonal operation to make up deficiencies in hydraulic power from low water or flood; absorption of load growth between stages of hydraulic development; operation as the main source of power. As reflected in the functions of the relay station and as affecting its design, hydraulic developments may be grouped as of four general classes:

I Minimum Flow Development. Developed hydraulic capacity equal to or exceeding maximum system load. Resultant minimum available flow only slightly, and for brief period in the year, below corresponding load requirements. Reserve provided in hydraulic station.

II Medium Flow Development. Developed hydraulic capacity equal to or exceeding maximum system load. Resultant minimum available flow below load requirements for considerable period, 40 per cent or more, of the year. Reserve provided in hydraulic station.

III Continual Relay Development. Available hydraulic capacity slightly below system load requirements throughout greater part of the year.

IV Supplemental Development. Hydraulic development merely an adjunct to the steam power station, which carries the bulk of the load.

The type of reserve referred to in Classes I and II is for relay against failure of equipment within the hydraulic station itself. Under the conditions outlined, this reserve may often advantageously be installed as part of the hydraulic station rather than in the steam station. As is well known, from 50 to 75 per cent of the cost of the average hydraulic development is fixed and independent of the capacity installed, so that sufficient capacity for this type of reserve may frequently be included at comparatively low unit cost.

Effect of Growth of Load. It will usually be found that the conditions represented by Classes I, II, and III are merely stages in approach to those of Class IV. This is especially true in the East. However, the change in relative status of the hydraulic and steam power stations may be very slow, particularly so where a series of hydraulic developments may be brought in successively, as warranted by load conditions; in which case to pass beyond the conditions of Class II may require a matter of decades. For these reasons the entire project should be studied broadly in the beginning both as to the ultimate physical possibilities and limitations of the hydraulic development, or developments, and as to the character and probable growth of the market for power. Neglect of such basic analysis in the initial planning of the development risks serious financial loss either in investment or in operating costs.

Seasonal Variation of Flow. The seasonal flow of the Hudson River in New York is so variable that the hydrographs of two successive years, 1915 and 1916, with their corresponding deficiency curves may be used in illustrating developments of all four of the classes just referred to. In Fig. 1 it will be seen that if this hydrograph is assumed to represent the year of minimum flow for a particular stream and if a flow of about 3000 sec-ft. would supply the maximum power requirement, a development providing proper equipment reserve at this flow would approximate the conditions of Class I. If growth of load raises the daily power demand above the capacity of the available minimum stream flow and this growth of load is accompanied by a corresponding increase of generating capacity of the hydraulic station to utilize, say, 8000 sec-ft.

[1] Consulting Engineer, Stone & Webster, Inc.

Presented at a joint meeting of the Boston Sections of The American Society of Mechanical Engineers and The American Institute of Electrical Engineers, and the Boston Society of Civil Engineers, February 7, 1921. Slightly abridged.

with proper reserve, the conditions become those of Class II. Turning to Fig. 2, development of the hydraulic plant to utilize a flow of, say, 10,000 sec-ft. to 12,000 sec-ft. with daily load demands somewhat in excess of the mean available flow, would give the conditions of relay service under Class III. Continued growth of load with a single hydraulic development as applied to either type of stream flow will ultimately bring about the conditions of Class IV.

Reservoir Storage and Pondage. Of course, in the case of many streams, it would be feasible to provide sufficient reservoir storage to smooth out the stream flow to a very material extent, thus raising the minimum or primary capacity of the potential development beyond the maximum load demauds considered above under Classes I and II at least, and possibly beyond that considered under Class III. For purposes of the present discussion, however, reservoir storage, as distinct from pondage in the usual sense, will not be further considered.

The effect of pondage upon the relay station requirements may be judged from reference to Fig. 3, which shows a typical manufacturing-town load with the "per cent load" curve superimposed for convenience of interpretation. If the minimum flow is assumed equivalent to 50 per cent of the day's energy requirement, with full 24-hour pondage provided, the hydraulic station could take off the upper 70 per cent of the demand, permitting the relay station to carry the base load at a daily load factor approximating 90 per cent with a demand only 30 per cent of the total. On the other hand, in the absence of pondage the relay station must be designed to carry about 75 per cent of the total demand, and on this basis its daily load factor would be reduced to about 40 per cent. It is apparent that, in the absence of pondage, higher capacity will in general be required in the relay station, and the relay-station load factors, both daily and annual, will tend to lower values than where full pondage is provided.

Relay Station for Minimum Flow Development

Referring again to Fig. 1, it will be seen from the deficiency

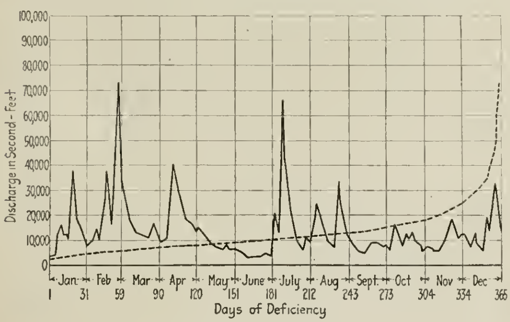

Fig. 2 Daily Hydrograph and Deficiency Curve for 1915, Hudson River Troy Dam, New York

curve that if the maximum load demand is within the capacity of the 3000-sec-ft. flow which is the developed capacity considered for Class I, the relay station except for conditions of equipment failure should not be called upon for operation in excess of 5 per cent of the year. It is not uncommon for relay stations under such conditions to stand idle an entire year. Obviously, for service of this character the actual operating economy of the relay station is of relatively small moment. The important considerations are low fixed costs and dependability.

As the load demands increase and the operating conditions for the relay station approach those of Class II, steam-power production costs are of slightly greater moment but in general are still tremendously outweighed by fixed charges and other costs independent of production. Usually it is only when the conditions of Class III are reached that the annual load factor of the relay station has risen to a value sufficient to make fuel economy as such an important factor in design.

For the extremely low load-factor conditions of Class I, type of equipment, dimensions and arrangement must all be studied with a view to attaining the desired output with minimum investment compatible with simplicity of station and low cost of attendance. Type of combustion equipment and the arrangement of furnace must of course be governed by the character of fuel available.

Coal in its more ordinary form will in general be the most satisfactory fuel. The stoking equipment should be of the forced-draft type for high capacity, either underfeed or chain grate, depending upon the class of coal. Draft facilities should be designed to take care of the maximum rate of combustion that can safely be maintained by furnace and grate over the period of peak load on the station. Economizers cannot be justified for the conditions of Class I, but it may be advisable to make provisions

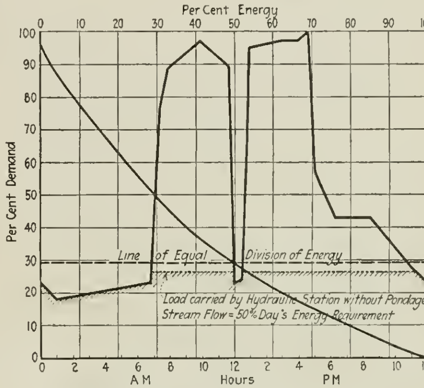

Fig. 3 Typical Manufacturing-Town Load
(24-hour load factor, 53 per cent.)

for their later installation to meet higher-load-factor conditions in the future.

The selection of type and size of boiler, decision as to total rated boiler capacity to be installed, and the proportioning of combustion equipment to boiler heating surface must take into account not merely the cost of that equipment only, but also the costs of building and all related equipment such as fuel- and ash-handling facilities, and mechanical draft. The cost curve of Fig. 4 shows that, for the particular case considered, when all related factors are taken into account boiler heating surface may be installed to the comparatively high ratio to grate area of 50 : 1 without appreciable increase of total boiler-plant cost. Higher ratios are accompanied by some increase of cost. The use of a lower ratio will result in needless waste of fuel.

Equally broad considerations should be applied to the design and proportioning of the condensing equipment. Considering the net increment cost of the boiler plant per unit of effective steam capacity and the increment cost of condensing plant for unit change of vacuum at the turbine exhaust, the condensing equipment should be designed to give the degree of vacuum under conditions of the required maximum load which will result in the lowest construction cost for the plant as a whole. In Fig. 5, which deals with a particular set of conditions, curve A shows the relative construction costs for condensing equipment to attain different degrees of vacuum, the cost of the 29-in. design being taken as 100 per cent; curve B, drawn to the same scale, the increase in boiler-plant cost resulting from the increased total steam demand which is had from different degrees of vacuum less than 29 in.; and curve C, which is a summation of A and B, still expressed in terms of 29-in. condensing-plant cost, the resultant effect upon total station cost, of designing the plant for different degrees of vacuum.

These two charts, Figs. 4 and 5, are correct, as to detail, for the particular conditions only for which they were estimated, but they clearly illustrate the interdependence of equipment costs and the importance of taking all related factors into account in deciding upon the type and size of apparatus. Similar considerations should be applied to the selection of generating units and to the determination of steam presssure and temperature.

Instrument equipment for mechanical apparatus such as boilers and condensers should be complete in so far as required as guides to efficient combustion and to the attainment of the highest degree of vacuum of which the condensing apparatus is capable; not that efficiency in the sense of low fuel rate is of special importance in this service, but that it is an essential to the attainment of maximum output from the major equipment installed which is the prime purpose of the station design.

It will usually be found advantageous to provide electric drive for one complete set of essential auxiliaries to permit starting these without waiting for steam. The main electrical features

of the relay station for the Class I conditions will be governed largely by the relation of the station to the rest of the system, provision being made to compensate for line or load characteristics wherever required.

Relay Station for Higher-Load-Factor Conditions

As the system load grows, if the period of relay-station operation is permanently lengthened, taking the development into the conditions of Class II for example, the higher load factor on which it may be possible to operate any new equipment may justify greater consideration of actual operating economy, condensing equipment may be of more liberal design, and boiler capacity may be added in greater ratio to steam demand, so permitting reduction of combustion rates.

Further growth of load and extension of the operating period for the relay station into the conditions of Class III will justify in new equipment still further consideration of operating economy; until, as the conditions of Class IV are reached, practically the same factors govern as in the usual independent type of central station.

As may be inferred from this outline of the progressive extension of the relay station to keep pace with the system's requirements, the relay station properly designed for low-load-factor conditions may be readily converted to a high-load-factor station, and so converted should operate as such with but a fraction higher total costs than the station specially designed for the higher load factor.

Fig. 6 shows the power costs from two types of station operating on the same conditions of load. Station A is designed initially for relay service under Class I conditions. Improvement in load factor is accompanied by the installation of such additional equipment and of such economic characteristics as may be warranted. Station B is designed for continuous operation at 50 per cent annual load factor. Its first cost is nearly 50 per cent higher than that of the initial step of station A and, while more economical at the load factor for which it is designed, on the lower range of load factors the higher efficiency of its equipment is insufficient to bal-

ance the higher fixed charge. Accordingly, where there is doubt as to the actual load factor at which the relay station may be called upon to operate, it will in general be advisable to design for the minimum probable load factor rather than risk unnecessary expenditure in providing for load conditions that may require years to attain.

If the fundamental design is right, the initially high operating charges characteristic of the low-load-factor station are readily outgrown, whereas the fixed charges, essentially higher for the high-load-factor station, are inescapable and remain until amortized a permanent burden on the development.

Emergency Reserve Type of Relay

Turning now to the station which must also function as an emergency, or breakdown, reserve, the emergency service required of such a station may vary from floating capacity for instant availability to merely providing against interruptions of several hours or days. The requirements in any particular case will be governed in a large measure by the character and importance of the load served.

The Rising Importance of Oil-Injection Type of Internal-Combustion Engine

A Review of the Development of the Internal-Combustion Engine From the Early Gas-Burning Type to the Present-Day Injection Engine Capable of Operating on Any Form Of Liquid Fuel Without Explosive Shock

By CHARLES E. LUCKE,[1] NEW YORK, N. Y.

ALL engineers are interested in the internal-combustion engine, whether directly concerned with its development or not, because it does stand for the highest efficiency in the transformation of heat into work. It is the most efficient prime mover with heat as the source of energy. Its promise of high efficiency on fundamental grounds is very old, but it is only within the present generation that hope has become even an approach to reality. Commercial success has become real in more and more fields of use and application all the time, and today we are able to appraise the situation as never before.

During this period the steam turbine has gone through its own period of development, and at this time when its limit of efficiency is in sight, the internal-combustion engine is actually twice as efficient, with the promise of more to come, in engines of good design and as favorably operated. Even with poor design or unfavorable conditions of operation the internal-combustion engine as to efficiency is practically as good as the best steam turbine of very much larger size.

Recognizing these facts, it is not difficult to understand the real and continuing interest in this problem of commercializing the internal-combustion engine. At the same time it is not at all clear just why it has developed along certain lines and not along others. Development along gas-engine lines—engines burning gas—has been a disappointment, and, taking the world as a whole, the gas-burning engine has not been much of a financial success.

In spite of such a discouragement, however, the internal-combustion engine has gone ahead and is today becoming a dominant, if not the dominant, new factor in transportation. Where it has failed in stationary practice with gas as a fuel, the reason is to be found in its high first cost and maintenance charges as against the low first cost and maintenance charges of the steam-turbine plant, which factors do not equalize through fuel saving unless the fuel cost is very high per unit and the load factor also high, conditions which have not generally obtained. On the other hand, in the transportation field the liquid-fuel applications are the ones that have come into favor because of their peculiar adaptability and the impossibility of competition by the fixed steam and hydraulic central stations on land. Even on the sea we find the motorship making very substantial headway against the steamer equipped with our most modern turbines.

Rise of Importance of Liquid-Fuel Development in the Combustion-Engine Field

This phase of the problem—the rise of importance of the liquid-fuel development in the combustion-engine field—is worth while analyzing. It is important for all engineers to know something about the business and problems of others, and on this assumption there should be general interest in the story of the adaptation of the internal-combustion engine to the uses of liquid fuel, so as to aid in the adaptation of the engines thus developed to transportation by the motorcycle, the automobile, the motor truck, the tractor, the railroad car or locomotive on land, by aircraft, and on the water by the motor boat and the motorship—in addition to certain stationary uses.

The first successful commercial machines of the internal-combustion class were gas-burning engines. While they have now sunk into a condition of more or less commercial insignificance, they have left behind a useful influence in that they have taught certain lessons that are of value in solving the problems of liquid-fuel adaptation.

The first lesson taught by the gas-burning engine is, the higher the efficiency the higher must the compression be. That is as it should be on thermodynamic grounds, and experience has amply demonstrated the validity of the theory. The second lesson is, that in addition to high compression, high efficiency is obtainable only if combustion is carried out in a correct and proper manner as to timing and rate. The gas-burning engine has also demonstrated that to get the maximum results in both power and efficiency it is equally necessary that the fuel be intimately and homogeneously mixed with the air throughout its entire mass, and that the cylinder be fully charged with that kind of mixture.

In addition to these principles of combustion for transforming high percentages of heat into work, the building of gas-burning engines has established many basic principles in the structural problem. To make cylinders, pistons and heads that will not crack is not as easy as it would seem, but taking the experience of the world at large, it can be said that reliable means of avoiding cracks have been devised.

In the adaptation of liquid fuel there are certain special problems that have to be faced that did not exist with the gaseous-fuel internal-combustion engine. The two principal classes of problems are in the fuel itself and in the special type of service to be met. It very early appeared there could be no such thing as a universal liquid-fuel engine equally good for gasoline, kerosene or fuel oil, or equally good for boats or automobiles or aircraft. There might very well be an automobile engine or a motorship engine, or a tractor engine, or a railroad engine, or a stationary electric-lighting-set engine, but each must be different.

It is this adaptation that occupies most of the period of development. To study the fuel phase of liquid-fuel adaptation, fuels must be divided into the two classes that are now found commercially but which division originally was not so clear. The first class includes fuels that are sufficiently volatile to make a more or less homogeneous and gaseous mixture with air by passing through so simple a device as a carburetor, which is similar to the older air-gas mixing valve of all gas-burning engines. The second may be termed the non-volatile class, and it includes anything that cannot be used in such a carburetor with or without heat, but which requires a device that must be built into part of the engine structure rather than a device or attachment to what would otherwise be a gas engine, thus initiating the injection oil engine.

The really difficult problem of the gasoline engine appears only when it is realized that the fuel available is no longer volatile enough to make the desirable homogeneous mixture, but not yet bad enough to require an injection engine. Before getting down to the problem of the injection engine proper, however, it is desirable to analyze some of the difficulties encountered in adapting the gas-burning engine and its principles of good utilization to light, and then to heavier, gasoline.

Difficulties Encountered in Adapting the Gas-Burning Engine to Light and Then to Heavier Gasolines

The first principle of maximum compression cannot be carried as far as is desirable because the ignition temperature of these gasoline mixtures is lower than that of the gases forming the bulk of the fuels for the more efficient gas-burning engine. Furthermore, the temperature of the mixture before compression is no longer under the complete control it used to be with cold gas, and the temperature at the point of ignition or when compression ends

[1] Professor of Mechanical Engineering, Columbia University, and Mechanical Engineer, 117 Broadway. Mem. Am.Soc.M.E.

Condensed from a paper presented at a joint meeting of the Boston and Worcester Sections of The American Society of Mechanical Engineers, the Boston Section of the American Institute of Electrical Engineers, and the Harvard Engineering Society, Cambridge, Mass., March 23, 1921.

is as much a function of the temperature before compression begins as it is of the amount of pressure rise.

The conclusions reached in gas-burning engine practice with regard to mixture quality, proportionality, homogeneity, intimacy, are all verified with gasoline. In proportion as that kind of mixture is attained with the volatile liquid fuel, so is it possible to attain some fair measure of the promise of efficiency, but the limit of attainment and the realization of it both fall off as the volatility falls off, and with the gasoline we are now using approximately only one half vaporizes in the intake passages.

The other half that will not vaporize is carried along in three different states: (*a*) as a film on the walls, such as rain will form on a window pane, (*b*) as a fog that floats, and (*c*) as a rain that is falling or driven by the air currents. A fog turns into rain, the

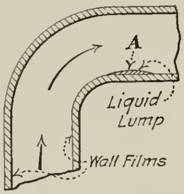

Fig. 1 Gasoline-Kerosene Carburetor Engine, Liquid on Manifold Walls

rain makes films and the action cannot go far before the fuel is all wall film. No amount of ingenuity with devices such as screens, baffles and paddles can prevail, because these cannot overcome the laws of liquid flow and vapor pressure that are operating. This is a problem of serious importance, because if the unvaporized liquid fuel gets into the cylinder and strikes a hot spot, such as the piston head, it will vaporize there locally, and will form on the piston head a "pancake" of vapor that will have displaced the air and not be mixed with it. This when combustion takes place above it, is simply heated to decomposition temperature, producing carbon, and though actually not burning itself, it fouls up the engine and interferes with its operation with a loss of fuel.

If the unvaporized fuel entering the cylinder strikes on a cold cylinder wall, it will run down past the piston into the lubricating oil. This unvaporized fuel is mainly kerosene and the lubricating oil is also a petroleum product. They are mutually soluble and as a consequence the viscosity disappears. The mixture is no longer a lubricant. It runs down into the crankcase and destroys the lubrication of the main bearings and the crankpins, as well as the piston pins. How can these things be prevented from happening? Unless they are prevented, the engine is no longer commercial.

Two courses of action are open. The first is to heat the mixture as it leaves the carburetor, and thereby raise the vapor pressure to a point where in a 15 to 1 proportion there will be a vaporized-fuel and air mixture at the minimum possible temperature and a pressure of one atmosphere. It may be said, therefore, that a moderate amount of heating is permissible, and possibly a sufficient amount to completely dry the mixture if the gasoline is not too heavy, but complete heating for a kerosene mixture is not. Gain will be realized, but also a loss, and the loss will overbalance the gain, and the practice must be abandoned.

The next mode of attack is to try to handle the mixture with some of the fuel as a liquid. To handle a wet mixture means really, in the modern multi-cylinder engine, to distribute the stream of liquid as it runs along on the inside of the pipes, to four, six, or more branches, giving to each the same amount of liquid in order that all cylinders may work the same, assuming the liquid will be vaporized or sprayed as it enters each cylinder. To accomplish this it is necessary to know how the liquid moves. Imagine the liquid coming up the side walls of the riser and approaching a bend as in Fig. 1. How would it turn? Observations in glass show that the liquid forms a very substantial lump at *A*, just beyond the turn, and on the inside of the bend. Films collect at the outside of the bend, but the velocity of the air-vapor mixture is so great at that point as to drive the liquid film around the bend to the point of least velocity. It is really the shape of the stream of air that the plug of liquid reveals.

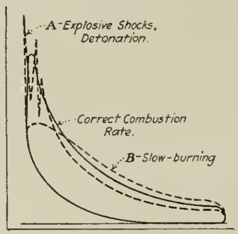
Therefore, if the gasoline is not very heavy, then a moderate heating of the mixture—not too much—with some form of hot spot is the right thing so as to avoid preignition, and with this moderate heating a manifold to take care of the distribution of the rest of the liquid.

Remedies Proposed

The net result of all this is that the gasoline carburetor engine is approaching a crisis in its history that is going to force the use of radical remedies. The remedies now being considered are as follows:

First, the elimination of the manifold entirely. This will take away the distribution problem and will permit the delivery of the liquid as a liquid with its air into the cylinder directly. No particular nozzle spraying is needed and not much vaporizing, because by properly forming the inlet valve and its passages a combustible foglike mixture will be formed as the charge enters the cylinder. This method has proved to be successful, and it is now the standard in use for all farm and most tractor engines, several hundred thousand of which are made every year, burning kerosene without any mixture heating whatever beyond what is incidental to suction.

Lubricating-oil contamination still is troublesome, and all such engines suffer from it to a greater or less extent. To minimize this the cylinder lubrication must be kept separate from that of the main bearings and crankpins. With admission of the mixture,



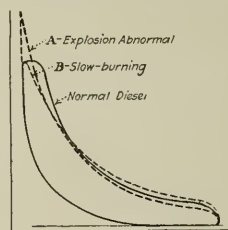


Fig. 2 Injection Oil Engine—Explosive Combustion
Fig. 3 Injection Oil Engine—Non-Explosive Combustion

however poorly vaporized, directly to the cylinder, good mixtures can be made without reduction of compression, but it is actually increased by adding water. This allows the water to enter the cylinder as a spray, just as the kerosene does, and by reason of its thermal, and to some extent its chemical, action, the compression can be raised so that some tractor engines and many farm engines have as high as 90 lb. compression.

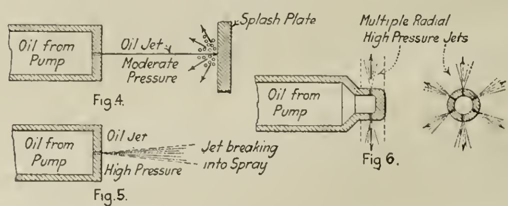

Fig. 4 Hornsby Jet-Splash Spraying Device
Fig. 5 High-Pressure Jet Breaking into Spray
Fig. 6 Multiple Radial High-Pressure Jets Breaking into Spray

The second remedy is to change the volatility of the gasoline by mixture with another and more volatile fuel. By properly selecting the things to be added to the gasoline, it is possible to not only improve the volatility, but at the same time raise the ignition point. Experiments with a benzol-alcohol-kerosene mixture at Columbia University have yielded truly wonderful results judged by the possibilities of the future. It is amazing to what extent compression can be raised on a charge of gasoline ready to preignite normally, with a minor amount of alcohol added. This is also true with benzol. Such mixtures carried the German aircraft through the war.

Abandonment of the Carburetor Engine as a Means of Solving the Present Motor-Fuel Problem

The third remedy—and this is the radical thing—is to abandon the mixture engine entirely and take up the injection engine. The abandonment of the carburetor engine, or the complete pre-mixture engine, is a thing that would solve the present fuel problem as we hear of it, and that fuel problem is a real problem. America is today facing a situation in its liquid-fuel supply that is one of the most serious things that has happened industrially. This country has reached the point where imports exceed exports. That means a real shortage. It is due to the motor-car and allied demand. Its direct effect is increased prices for those volatile constituents that are in greatest demand, but without a corresponding increase in price for such residuals as are not in demand. A switchover from the carburetor engine, which requires the light distillates, to an injection engine—independent of the distillate and of a kind which is independent of volatility, operating with anything having proper fluidity—would mean that the automobile industry would be revolutionized. Such a step cannot be taken suddenly. It is a difficult job, but it is possible to explain the difficulties and to state the progress that is being made in solving them. Not only is this a matter of interest to the engineer, but it is a matter of national importance.

In case of the successful development of a suitable injection engine the problem of gasoline shortage disappears, because the injection engine can handle any petroleum distillate, any coal-tar product, any alcohol or similar fuel, subject to the one condition that it shall be of proper fluidity to pass the pump valves and spray finely at the spray orifice. If a fuel is not naturally of high fluidity, there is not one that cannot be made of proper fluidity by adequate heating. The temperature of heating, however, must not be carried so far as to cause a decomposition with carbonization and cracking.

Injection and Carburetor Engines Compared

The injection engine, compared with the carburetor engine, not only makes engines independent of the grade of fuel (there is only one requirement besides its viscosity—cleanliness), but it presupposes that there will be under compression only air, and that only after compression shall the fuel be injected. This means that by properly choosing the time of injection the compression may be as high as pleases the designer. There is no longer any limit of temperature of ignition, because there is nothing to ignite. As a consequence the injection engine has higher possibilities of efficiency, and those possibilities are attainable, and attained.

Another difference found between the injection and the carburetor engine is that due to the difficulty in making the fuel reach all of the air. With the gas-burning engine and with the carburetor type of volatile-liquid-fuel engine, a mixture is made externally and every part is actively combustible, so that there will be the maximum possible work per cylinder charge for a given compression and shape of combustion line. With the injection engine there are certain real advantages, as pointed out, but if after compression of the air charge the fuel is quickly thrown in, it will be difficult to reach all of the air in an unfavorably shaped combustion chamber from a single point of injection.

There must be a means of spraying the oil into a charge of dense air—air of a density up to 30 or 40 atmospheres means of arranging to get the injected fuel in contact with as much of the air as possible, and means of preventing the delivery at any point of any considerable amount of fuel that cannot reach air, because in that case carbon will be formed and smoke produced which will choke up the engine in time.

The Two Classes of Injection Engines

The means of carrying out the operations that are peculiar to the injection engine are divisible functionally into two classes. The air must always be compressed. It may be compressed to ignition temperature and higher, so that the fuel as injected into it ignites immediately and burns as fast as it gets in, the rate of combustion being the rate of injection and controlled by mechanical means. On the other hand, it may be compressed not to ignition but to something less than ignition temperature, and then the fuel injected suddenly to form an explosive mixture which will burn as nearly instantaneously as may be. This gives us two classes of injection engines. The first, the correct operation of which is shown in the indicator card of Fig. 2 in full lines, is explosive in type, and if the combustion is imperfectly carried out there may result explosive shocks as shown at A, or slow burning as at B in dotted lines; the other, shown in Fig. 3, carries the air to a higher compression pressure, so as to have it not only as hot as the ignition temperature but somewhat hotter. This will give a non-explosive combustion at substantially constant pressure according to the full line, but if combustion be carried out imperfectly, or deranged as to timing of injection or combustion, it may produce explosive shocks as at A or slow burning as at B according to the dotted lines.

Each of these two classes is subject to certain derangements or diseases peculiar to a given mechanism, but comparing the two properly adjusted, how do they stand with reference to each other? Is there any great choice, any reason why the advocate of one should call the advocate of the other wrong? Not at all. Each is justifiable on the grounds of efficiency, power and practicability, so that the real problem boils down to one of mechanical questions of relative cost, reliability, foolproofness and adaptability to service conditions. The two are related in this simple manner as to efficiency. If the compression of the first with explosive-type combustion is about half the compression of the other burning the fuel at substantially constant pressure, their efficiencies are substantially the same. In the former case, if an explosive mixture is to be made, the compression must be kept X degrees below the ignition value in order to keep it under control, and in the other case Y degrees above ignition temperature to insure prompt ignition after injection.

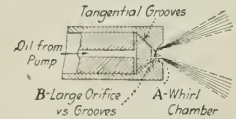

Fig. 7 Single-Orifice Whirl-Chamber Spray Nozzle

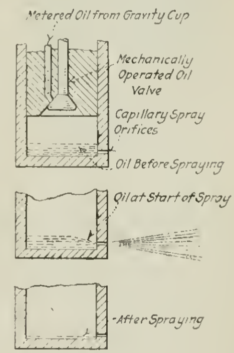

Fig. 8 Hvid Air-Spraying Cup

Assuming the exponent n in the equation $PV^n = C$ to have a value of 1.4, it appears that 150 lb. compression will produce the ignition temperature of kerosene (998 deg. fahr.) if the initial temperature is a little less than 250 deg. fahr., and if an explosive mixture is to be formed and not preignited, a margin of 100 deg. below ignition will be attained with an initial temperature of something under 200 deg. and a margin of 200 deg. with about 175 deg. fahr. initial. For fuel oil having an ignition temperature of 1070 deg. fahr. the same conditions will be brought about by the same compression when the initial temperatures are 300 deg. fahr., 250 deg. and 200 deg. respectively.

On the other hand, if the air is to have a safe margin of temperature over the ignition value before compression, higher compression or higher initial temperatures are necessary. For solid-injection sprays it is generally assumed that 200 deg. margin is safe and for air spraying 400 deg. margin. For the latter case a compression of 450 lb. is pretty generally adopted, and this will be secured with a little over 250 deg. initial with kerosene and a little less than 250 deg. with fuel oil. Solid-injection ignition may be produced with equal reliability with less compression, or with lower initial temperature, or both.

Methods of Spraying Fuel Employed in Injection Engines

The first mechanical problem in connection with this injection engine is that of making the spray, and one might say, in a way, that the building of the engine begins with the forming of a chamber around a spray. The simplest way of making a spray nozzle, introduced by the first successful commercial engine which was brought here from England—the Hornsby—consists in drilling a hole in a plate. Through this a jet is projected which strikes the wall, a spray being formed by splashing (Fig. 4). If the hole is

reduced in size, or if supplied with oil under much higher pressure, the oil will move proportionately more slowly on the sides as compared with the center, and finally the entire jet will expand into a fine mist (Fig. 5).

The essential characteristic of such a spray is strong penetration power. What is necessary, however, is some means of spreading. This can be secured by multiple holes (Fig. 6). It can also be secured by using slots which are normally closed but which are opened by the oil pressure deflecting the metal. Spread can be secured also from a single spray orifice by giving the oil back of the orifice a rotary motion just as in the mechanical atomizer oil burner as developed for the Navy (Fig. 7). Here the oil grooves are arranged to deliver tangentially into a small whirl chamber A, so that the oil in the chamber will have a rotary motion, as also will the oil issuing from the end of the orifice B at the outlet from the chamber. If the orifice B has an area many times greater than the area through these grooves, there will be no residual pressure in the chamber A, and in this case with sharp edges oil spray will issue in a hollow cone form, due to a pure centrifugal whirl. The spray will have a good uniform spread with little or no penetration. If, however, orifice B be narrowed down so that it is smaller than the grooves in area, there will be residual pressure in the whirl chamber A, producing axial velocity also, and the cone spray becomes narrower and solid. The spray will then have less spread and more penetration.

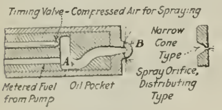

Fig. 9 Air-Spray Valve, Open Type

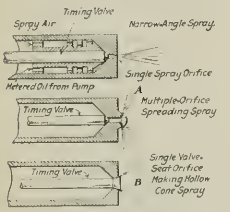

Fig. 10 Air-Spray Valve, Closed Type

In addition to this method of solid-injection spraying there is the air-spray system. This in its simplest form (Fig. 8) consists of a cup with liquid fuel in the bottom, compressed air above the fuel, and a small hole in the side at or below the oil level. As the air escapes through the hole there is first a depression of the liquid right at the point and the liquid is carried to the orifice by the air flow across its surface and blown out, being sprayed by the higher velocity of the air. Such a spray is fine and has good penetration, but not much spread.

A modification giving somewhat better control is shown in Fig. 9, which has a depression in the passageway at A, in which the fuel is deposited as a pool. A deflector over the oil directs the air down and across its surface. The air in motion will tear the liquid off from the surface and this may be delivered to the cylinder in a narrow cone spray through a contracted orifice A, or through multiple orifices as at B, to get an adequate spread. This form is the so-called "open air spray" of the Diesel engine.

Next there is the so-called "closed air-spray valve," in which a valve seats on the outlet of a passage as in Fig. 10, and which when lifted allows the air to flow. The oil is delivered by the pump into the passage and spreads out on plates usually provided with holes, grooves, or slots so as to offer a large amount of surface to be wetted by the oil, which can be blown off gradually and delivered as a spray through a single or multiple orifice A. Such a spray has a narrow angle, strong penetration, and little spread except as may result from impact and rebounding. This is the most common air spray of the Diesel engine. To secure more spread directly, the valve can be reversed in seating as in B.

For any give form of spray, air or solid, there must be a suitable combustion-chamber form, or for any given combustion-chamber form there must be selected a spray of suitable shape or energy to best reach distant air, with always the possibility of setting up turbulence or internal air currents as a corrective means.

Diesel Engines and Their Limitations

The first class of engines to be noted under the injection type is the one that is most successfully used commercially—the air-injection Diesel engine—and which normally has about 450 lb. compression—more than is sufficient to ignite an ordinary oil, enough more to be safely above ignition temperature all the time. Such engines are normally rated at 70 lb. brake mean effective pressure but are capable of producing over 100 lb. if the metal can stand the intense heating. A fuel consumption of from 0.4 to 0.45 lb. per b.hp. per hr. is standard. They are built in all except very small sizes with cylinders up to about 36 in. diameter, depending on speed and mean pressure. The maximum size is limited by the same internal heating conditions with tendency to crack the metal as obtain for large gas engines. The air-compression Diesel engine is in successful use, as is well known, for both stationary and marine purposes, and is the standard oil engine in use for large ships.

Certain limitations of the air-injection Diesel engine make it unsuitable as a substitute for the gasoline engine. It cannot be made to work with cylinders of too small a size without abnormally high compression, because of the cooling conditions that exist during compression, and in the smallest practical size it is too expensive and too complicated. The control of the air spray is peculiarly delicate. The air for it must be provided by an attached air compressor, and it requires a pressure of never less than 600 and often 1300 to 1500 lb. per sq. in. Such a compressor small enough for the purposes of an automobile is a mechanical absurdity. The particular field to which the air-injection Diesel is not at all adapted, therefore, is that of the small-cylinder high-speed engine, and that, in the internal-combustion market, is the biggest field of all.

Desirable Features of Semi-Diesel Engines

To approach the problem of the small injection engine, what is available as a starting point? The nearest thing is a type of engine that has been on the market for some time and which is commonly known as the semi-Diesel. These have a feature particularly attractive in the small-engine field—that of operating with so-called "solid-injection or airless spray" that eliminates the air compressor and the delicacy of adjustment of an air-spray valve system. They are simple, but do not operate nearly so well as the air-injection Diesel engine. One feature of this class is hot metal, which plays in these engines the function of more or less vaporizing the fuel and also and mainly that of ignition. This hot metal, when an external wall, is always a fire risk. On a ship it may be serious and in many buildings it is prohibitive. A hot-metal combustion chamber is practically an auxiliary pressure-enclosing wall and thereby constitutes an element of some danger of breakage. The temperature of the hot metal is difficult to control within proper limits, and sometimes impossible.

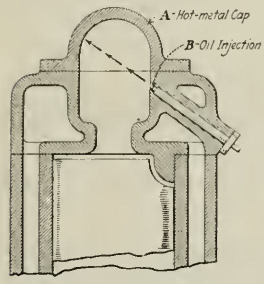
These semi-Diesel engines of hot-bulb, plate or tube pattern cannot be described in detail because of lack of space. They differ from each other mainly in the hot-metal form, or location, and the combustion-chamber shape with reference to oil injection. An unjacketed cap A (Fig. 11) more or less hemispherical, closing a water-jacketed chamber connected to the cylinder by a neck, with an oil-injection nozzle B arranged so the jet strikes the hot cap to produce ignition by contact, is typical of a group of engines that started with the Hornsby.

Cold-Wall Explosive-Combustion Solid-Injection Engines

As a result of a fairly general knowledge of the conditions surrounding these so-called solid-injection semi-Diesel engines, attention has been directed toward substitutes that would have some of the good qualities they had—simplicity, cheapness, foolproofness—as well as the good properties of the Diesel—cold walls, ignition by compression, and cleaner combustion with greater independence of fuel quality. Efforts to produce a cold-wall engine are directed along both lines. One is the explosive-combustion engine; the other, the non-explosive-combustion engine. Cold-wall explosive-combustion solid-injection engines are comparatively new. The British Crossley (Fig. 12) has a piston with a conical end and a cylindrical projection A. The cylinder head is completely water-jacketed. As the piston approaches the head, the projection A will pass the corner of the cylinder head, at which time the air in the annular space B is trapped. This projection is a loose fit but not too loose, so that during the time it is passing into the head bore there is a violent annular stream of hot compressed air cylindrically distributed down the sides of the combustion

chamber and back along the center. Into that stream of air is injected a fine spray of oil that is instantaneously ignited, burning as fast as oil and air come together. The combustion is explosive in type but not in fact.

An American representative of the same class of engine is found in the Price construction (Fig. 13), which works differently and in which the combustion is normally explosive in fact. Here a fine spray is injected into a conical combustion chamber A on each side of a central cylindrical chamber B, up which a gentle air current rises during compression. This serves to help mix the fine spray with the air during the last of the compression stroke. Compression is adjusted so that the ignition temperature is reached just before the end, and as the air charge before compression is cooler at no load than at full load, the misfires that would happen, due to failure to reach ignition temperature, are prevented by an air throttle having the effect of retaining enough hot burnt products to avoid misfires. Should the air charge get too hot from any cause, the whole charge might be ignited everywhere at the same time before compression was complete, producing a detonating combustion with explosive shock. Later injection would correct this if the charge were hot enough or compression high



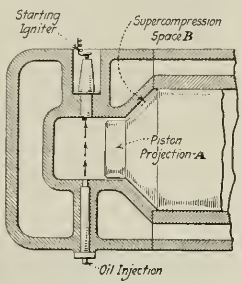


Fig. 11 Hornsby Type of Combustion Chamber
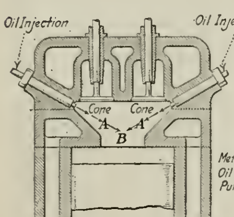
Fig. 12 Crossley Cold Combustion Chamber



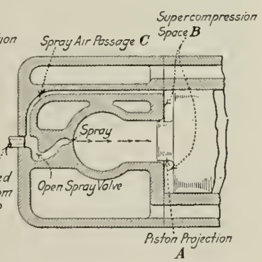


Fig. 13 Price-Ingersoll-Rand-De La Vergne Cold Combustion Chamber
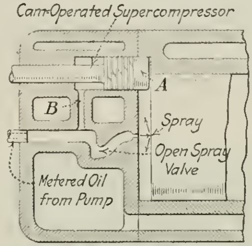
Fig. 14 Haselwander Cold Combustion Chamber

enough and make the action like that of the Crossley engine, where timing of injection is depended upon to prevent detonating shocks, as is spark timing in mixture engines burning gas or gasoline.

These engines are real modern improvements. They can, with a comparatively moderate compression—200 to 250 lb.—give a fuel consumption that is substantiallly equal to the Diesel with its 450 lb. compression, but they must deal with a real difficulty. The combustion is essentially explosive combustion in fact or in type, and with explosive combustion not correctly timed—a little too early or too fast—detonations, either regularly or intermittently, are almost sure to occur. The shocks due to these detonations constitute one of the objections, and this has led other designers and investigators to devote their attention to a new class of solid-injection Diesel engines with non-explosive combustion in cold walls, the attractive features of which are less or no tendency to detonate, greater ease of maintaining correct combustion, and equally good fuel consumption.

Solid-Injection Diesel Engines with Non-Explosive Combustion in Cold Walls

An early attempt to eliminate the air compressor from Diesel engines was made by the German Haselwander, as shown in Fig. 14, which is practically a Diesel engine with air injection but without a compressor. An open type of air spray is combined with a piston construction embodying a cylindrical projection A that traps air in the space B. A passage C leads this air around to the spray nozzle. The end of the piston supercompresses part of the charge of air, driving it over the fuel and causing it to deliver a spray into the cylinder. The difficulty is that there is no control of timing. Any change in the leakage between the piston



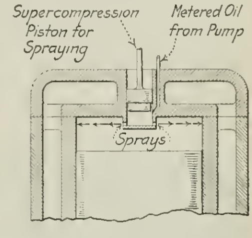


Fig. 15 Trinkler-Korting Cold Combustion Chamber
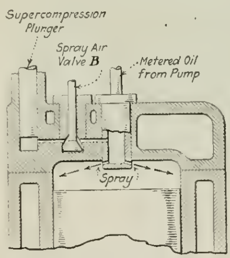
Fig. 16 Hoflinger Cold Combustion Chamber



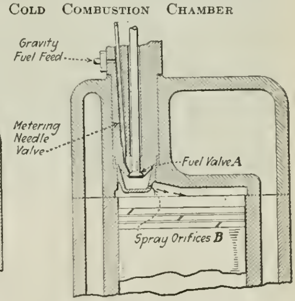


Fig. 17 Gernandt Cold Combustion Chamber
Fig. 18 Hvid-Brons Cold Combustion Chamber

projection and the walls changes the timing, while carbon causes a binding action. There is also a tendency toward reverse flow on the outstroke.

A modification of this engine designed by Trinkler and built by the German firm of Körting is shown in Fig. 15. Trinkler added a small piston A in a cylinder connected with the main cylinder at both ends. Just at the right time the piston A was moved out by a cam control so as to force air from the back end through the passage B to the spray nozzle. This little auxiliary piston A furnished the charge of supercompressed air for spraying the fuel, and it was timed like the old make-and-break ignition of the gas engine. The objection to it was that it tended to stick and stop the engine.

In Höflinger's proposed engine, Fig. 16, a small cuplike cylinder with a piston projects into the working cylinder. A passage for oil is connected below the piston and before the fuel is wanted it is deposited by the pump in that cup or bottom end of the small cylinder. Just when it is wanted a timing cam drives the piston down, compressing air on top of the fuel charge and expelling both through holes A in the side as an air spray. So far as is known, this engine has not been built, but it is very suggestive, especially when considered along with the very modern one reported from Detroit by Gernandt, Fig. 17, with special reference to use for automobiles. This has the Höflinger cup and fuel feed, but with a connection to a timing valve and to an auxiliary cylinder with a piston. The piston of Höflinger's cup is replaced by an independent piston A and separate timing valve B. Then at the right time the piston descends, the valve opens by a cam movement and the charge of air is supplied to the cup, spraying the oil into the cylinder.

Finally, the simplest of all in this class and the one form that has come into almost universal use for small stationary engines, and has practically no competition in its own field—farm units—is the Hvid, shown in Fig. 18. The Hvid retains the same fuel cup as the last two engines but with entirely different connections for fuel and provisions for supplying and timing the spraying air. The fuel is delivered into the cup by gravity through a mechanical valve *A*, so that after it is in the cup the latter is a closed chamber. The fuel is delivered into the cup long before injection, in fact, before compression begins. During compression air flows into the cup through three holes, *B*, which prevent the outflow of oil prematurely, provided the holes are small enough so as to be capillary. After compression is complete, the air in the cup has a lower pressure than the air in the cylinder, which differential is quickly equalized on the expansion stroke. As soon as the cup pressure exceeds the cylinder pressure, the cup air will spray the

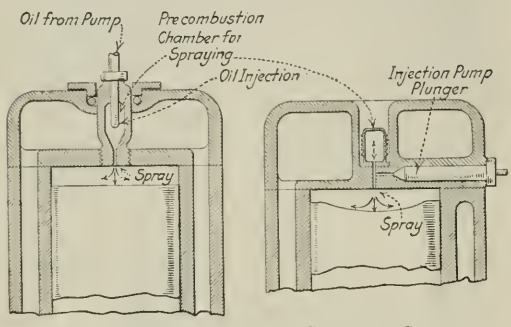

Fig. 19 First Steinbecker Cold Combustion Chamber
Fig. 20 Present Steinbecker Cold Combustion Chamber

oil into the cylinder. If the holes are too large, fuel will leak into the cylinder while the cup is being charged. If they are too many, the air escaping into the cylinder will come out of some without spraying oil out of the others. There is a limit to both the number and size of the holes and the net result is that the Hvid cup seems to be limited to small cylinders, but in a small cylinder where a small number of capillary holes will pass the right amount of oil it is thus far supreme. It is the simplest possible, automatic in timing because cylinder pressures control the timing of the spray, and the only objection is that the combustion is a little late or slow. This little engine may be said to represent the limit of commercial success for small engines with solid injection supplied by air without an air compressor.

Steinbecker has devised another spraying scheme which has been worked out experimentally. In the form shown in Fig. 19 a very small bulb-like chamber with a narrow neck is connected to the cylinder head. Through the top of this chamber a spray nozzle projects and delivers a jet or a coarse spray into the neck. At this time the air has already been compressed to and above the ignition temperature, so that as the oil escapes it immediately ignites, but not much can burn because not much of it can reach air in the narrow passage. What burns on the back face of the spray, according to Steinbecker, will raise the pressure in the bulb so as to produce an outflow of gases to respray finely what oil has been delivered to the neck and deposited on its walls. By the rise of pressure in the bulb, Steinbecker expected to really spray the main charge of oil.

Steinbecker has a recent engine, Fig. 20, in which the bulb chamber is retained, the neck passage is made extremely narrow so as to get a very high velocity through it, and injection pump delivery is led into the middle of the neck. It is timed so that oil enters near the end of the compression stroke while there is still some upward flow of air from the cylinder to carry it into the bulb chamber, which is unjacketed and hot, so as to produce ignition and combustion by explosion. The hot gases produced cause a reverse flow to the cylinder and spray the oil delivered later directly into the cylinder. This is Steinbecker's engine as it now stands, and as operated experimentally even in automobiles. The timing is directly by the pump, and should that pump force the oil in too soon, there would be an explosive shock. If the timing were wrong, the correct amount of oil would not enter the bulb and the spraying would fail also. It is probably quite sensitive to pump timing, as is not the case with some others, including the Hvid.

The Divided Combustion Chamber as a Means of Preventing Detonating Shocks

One of the great difficulties with injection is to prevent the development of explosive shocks by too early, and loss of efficiency by too late, timing. Rapidly recurring detonations will wreck any machine in time. To direct the oil stream into the combustion chamber by a pump, without any other means of control of time and rate of combustion, is a method employed by Vickers in England, using a central pressure supply of oil admitted to spray valves by cam-timed oil valves. The equivalent was worked out by Junkers in Germany, using direct pump injection without timed oil valves, who succeeded in making it work in an aircraft engine, and to him is due the credit of first making a solid-injection heavy-oil engine that would fly in the air. In both cases, however—the German and the British—the fuel went directly into the cylinder and the production of detonating shocks was entirely a question of avoiding too early an injection—and earliness and lateness are a matter of a few degrees of crank angle. They must be extremely sensitive.

Here a different principle, intended to prevent detonating shocks and relieve the engine of the necessity for accurate timing, claims attention. In accordance with it the main combustion chamber is divided into two parts, one in the cylinder and the other removed—a divided combustion chamber. The air is compressed partly in the cylinder and partly in a connecting pocket, the major part in the former.

The first construction embodying this principle to be noted

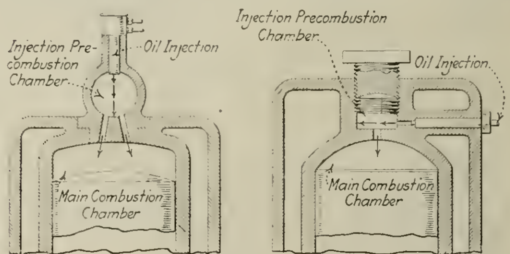

Fig. 21 Nydahl Divided Cold Combustion Chamber
Fig. 22 Nielsen Divided Cold Combustion Chamber

here is a Scandinavian one by Nydahl, shown in Fig. 21. He provided a spherical chamber connected to a cylinder by a series of holes and with an oil spray at the top. The piston stops at a point that leaves considerable air in the cylinder. There is a body of air in the cylinder and another body in the injection chamber at dead center. If the quantity of air in the injection chamber is small enough in comparison with that in the cylinder, then when the fuel is injected—the whole charge of fuel into the small amount of air—it cannot produce any explosive shock because so small an amount can burn. What, then, will happen to the rest of the fuel? It will change as it would in a gas producer where fuel reacts with less air than is required for combustion. Some of it will burn; the rest will gasify; possibly some will merely vaporize. In this divided-combustion-chamber construction the piston becomes the principal element of combustion timing, somewhat as in the Hvid engine because the main combustion is produced by the flow from injection chamber to cylinder. The divided combustion chamber is the principal element in preventing the explosive shocks, the piston movement controls the completion of combustion, and if the compression is high enough the whole structure can be jacketed.

Such a water-jacketed injection chamber, but of more or less cylindrical form, and embodying the divided combustion chamber and side injection of fuel, is shown in Fig. 22. This is a Danish

Design and Construction of the 16-in. Disappearing Carriage from an Engineer's Standpoint

By MAJOR G. M. BARNES,[1] U.S.A., WASHINGTON, D. C.

I HAVE been asked to give you some of the details of the design and construction of the new 16-in. disappearing carriage for harbor defence. It was suggested that this Society would be interested in the construction of this large gun carriage from an engineering standpoint. I will therefore try to avoid any consideration of the carriage as a piece of ordnance and will describe it as a large machine, hoping that some of the problems which have been solved in the development of this large mount may be of interest and possibly may have some direct application to other engineering problems in which you are more directly interested.

This weapon is a 16-in. high-power gun, mounted on a disappearing carriage, especially designed for seacoast-defence purposes. The gun weighs 170 tons, while the carriage upon which it is mounted weighs an additional 670 tons. When emplaced in the seacoast fortification the gun and carriage will be in the rear of an embankment of sand and concrete of such thickness that the highest-power naval guns can not penetrate it.

As this embankment will reach nearly to the height of the gun when the latter is in the firing position, only the muzzle will be seen from the ocean side. When firing, the shock of discharge, which is equivalent to a force of over eight million pounds acting along the axis of the bore, drives the gun from the firing position into the loading position (Fig. 2), which is approximately 12 ft. below the position of the gun as shown in Fig. 1.

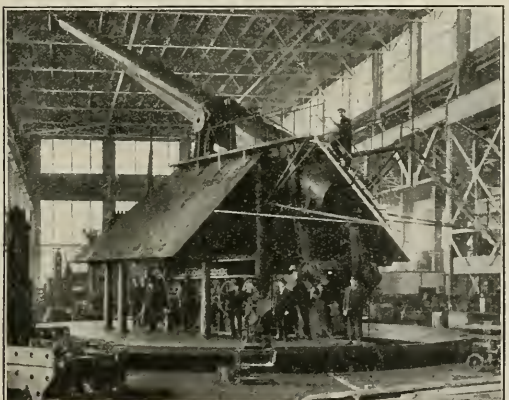

Fig. 1 16-in. Disappearing Carriage, Model of 1917

The gas pressure acts during the time the projectile is in the bore and for a short time thereafter. The force of explosion of the gun must be absorbed in the carriage so gradually and to such a nicety that there will be no shock or vibration to the carriage parts when the gun moves from one position to another. The gun pointer, who is stationed only 7 ft. to the left of the gun, must be able to keep his eye at the telescopic sight during firing and continue to direct the gun upon the target.

Although the gun and the carriage weigh approximately 840 tons, they can be easily turned in direction by the power of one man applied at the traversing handwheel. The armor-plate shed shown in the illustration protects the carriage and the gun crew from small shell fragments, concrete and débris which might fall about the gun if enemy shells should strike the parapet.

[1] Chief of Railway and Seacoast Carriage Section, Ordnance Department.

Lecture delivered at a meeting of the Washington, D. C., Section of The American Society of Mechanical Engineers, March 31, 1921.

Principal Parts of the Carriage

Fig. 3 shows diagrammatically the principal parts of the carriage. The gun is attached to the upper end of the gun lever by means of its trunnions. The gun levers are trunnioned near their centers to the top carriage, which is constrained to move up a plane inclined 1 deg. to the horizontal. The lower ends of the gun levers are connected to a crosshead, which is constrained to move vertically in guides.

A very heavy counterweight (315 tons) is attached to the crosshead. The function of this counterweight is to raise the gun from the loading or the recoiled position to the in-battery or firing position. The elevating arm, which is attached to the gun near

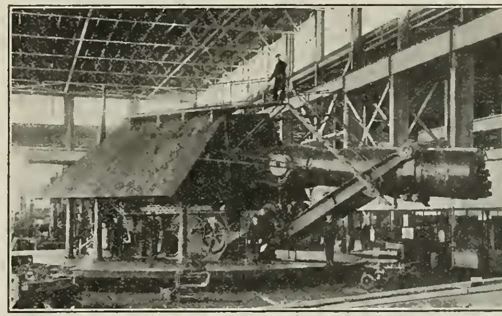

Fig. 2 16-in. Disappearing Carriage, Loading Position

its breech end, controls the elevation of the piece. The lower end of the elevation arm can be moved up or down. The slide, to which this end of the elevating arm is attached, is constrained by the rear bracket casting to move in the arc of a circle, the center of which is the position of the elevating trunnions in the loading position. The breech of the gun will therefore always return to the same position for loading, regardless of the angle of elevation at which the gun is fired.

When the gun is fired the shock of discharge is absorbed mainly in the following ways:

1. In raising the counterweight
2. In throttling oil through the varying orifices in the recoil cylinders, which are built into the top carriage
3. In moving the gun, gun lever and top carriage from the in-battery to the recoiled position.

Forces Acting on the Members of the Carriage

In designing the carriage it is necessary to make a complete solution of the forces acting on the various members and to proportion the parts accordingly. The method used in determining these forces is given in detail in the book Stresses in Wire-Wound Guns and in Gun Carriages, by Col. L'H. Ruggles, Ordnance Department, published by John Wiley and Sons, Inc. Any one particularly interested in the mathematical solution of the forces acting on a carriage of this type will find a very complete solution in this book.

The maximum stresses occur in different members at different angles of elevation. It is therefore necessary to make calculations at various angles of elevation to determine the maximum stress which occurs in each member. Fig. 3 indicates the maximum stresses in the principal members of the 16-in. disappearing carriage when the gun is fired. The accelerations of the principal moving parts along the x and y axes are also given.

It will be noted that the force of the powder gases amounts to 8,700,000 lb. This force is reduced at the trunnions to P =

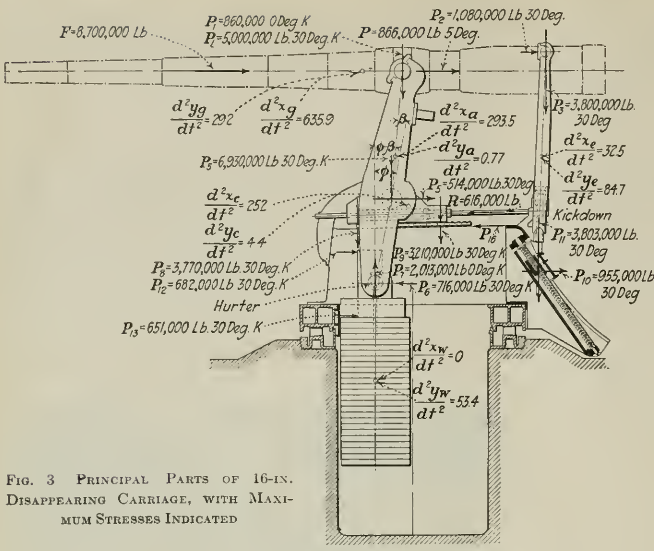

Fig. 3 Principal Parts of 16-in. Disappearing Carriage, with Maximum Stresses Indicated

866,000 and P_1 = 860,000 at 0 deg. elevation. At maximum elevation P_1, however, becomes 5,000,000 and the carriage parts must be designed to withstand this force. It is interesting to note that P_7 exceeds 2,000,000 lb. The value of the counterweight in absorbing the energy of fire is therefore apparent. The piston-rod pull is 616,000 lb., and is assumed to be constant throughout the length of recoil.

It will be seen that the forces P_2 and P_3 acting on the upper end of elevating arm are very large. These forces have been computed on the assumption that this arm is rigid. In order to reduce the force on the elevating arm, it has been made elastic; that is, a second recoil mechanism has been introduced. This recoil mechanism allows the arm to shorten when a large stress is brought upon it. As soon as the stress is relieved, the arm returns to its original length. The introduction of the elastic arm slightly increases the stresses in the gun levers and other members, which must be computed on this basis. The arm still fulfills its function of keeping the gun at the proper elevation.

The Recoil Mechanism

A part of the energy of fire is absorbed in the recoil mechanism. This mechanism is simple and consists of two cylinders located in the top carriage. The piston heads and pistons are stationary, while the recoil cylinders move back and forth. The cylinders are formed by two forged-steel liners slipped into the longitudinal holes in the top carriage. Two bars, called throttling bars, are bolted to the interior of each cylinder. Two corresponding notches are cut in the piston head. The upper surface of the throttling bars is a curved surface and so proportioned that the pressure in the cylinder is constant over the length of recoil.

The arrows indicate the direction of the flow of oil during recoil. The piston rod and head remain stationary while the top carriage moves to the rear. The length of recoil can be controlled by means of the throttling valve, which when open allows the oil in the recoil cylinder to pass to the low-pressure side without throttling past the throttling bars. When the gun goes from the out-of-battery to the in-battery position, the top carriage moves forward and the direction of the flow of oil is reversed. Just before the gun reaches the in-battery position the counter-recoil buffer acts. As the male buffer, which is part of the piston head, enters the rear end of the cylinder, the oil is gradually forced out. The remaining energy in the gun and counter weight is thus gradually absorbed and the gun comes to rest without shock. This action can also be controlled by means of the buffer valve, which when open allows the oil to escape to the recoil cylinder.

There is also another device used to help absorb the final energy at the end of recoil and counter recoil. This system, called the "hurter" system, is shown below the cylinders (Fig. 4). Just before the counterweight reaches its upper position it strikes the lower end of the hurter cylinders. The pistons of the hurter cylinders are rigidly attached to the carriage and are stationary while the cylinders are movable. Oil in the lower part of these cylinders, which is the high-pressure side, throttles past the recoil stem, up through its center and out into the low-pressure side. Also before the counterweight reaches its lower position the hurter cylinders are forced down by the expeller cam and the reverse action takes place. The recoil stems are

Control of Corrosion in Iron and Steel Pipe

Corrosion of Iron or Steel in General—Protection of Pipe Against Exterior Corrosion—Internal Corrosion of Water Pipe and Its Prevention

By F. N. Speller,[1] Pittsburgh, Pa.

While there is a vast difference in the amount of corrosion of iron and steel under different conditons, and it has been proved that the relative corrosion of these metals also varies decidedly with surrounding conditions, there are certain fundamental causes which underly all cases of corrosion which should be understood by all who are interested in this problem in any of its phases.[2]

Every metal when placed in water is subjected to a fixed tendency to go into solution. This is wholly a matter of electrochemical activity and varies to a definite extent with each metal. Thus the initial reaction in the process of corrosion is analogous to solution in acid, pure water being in effect a very weak acid. The acidity of the water depends on the concentration of the hydrogen ions, which determines the initial speed of attack. As in all electrochemical reactions, however, the initial speed of solution soon slows down as the numerous little electrochemical couples which form over the surface of the metal become "polarized" due to the accumulation of hydrogen on their cathodic surfaces, ultimately stopping the solution of the metal. In the case of iron a small amount of the metal (less than 10 p.p.m.) is dissolved as ferrous hydrate, which also has a decided retarding action on the solution of the metal. This, the first stage of the corrosion of iron, while essential, is not a serious matter if the reaction between water and iron can be stopped at this point. As a matter of fact this reaction cannot proceed unless in some way or other the hydrogen film protecting the metal is removed. This is usually brought about by means of something in the nature of a depolarizer, generally free oxygen, which also combines with ferrous hydrate forming insoluble ferric hydrate, commonly known as rust.

This, the second stage of corrosion, is thus caused by the oxidation of hydrogen and ferrous hydrate in solution by the free oxygen of the atmosphere. Oxygen is soluble in water at normal temperature to the extent of about ten parts by weight per million (7 cc. per liter), and as water readily absorbs more oxygen when this element is used up, as in rusting under atmospheric conditions, it will be seen that under such conditions the reaction will continue until the metal has been destroyed; or the reaction may be brought to a stop at any time through exhaustion of the supply of available oxygen.

Water and oil lines suffer mainly from outside corrosion due to soil conditions, which resembles more nearly corrosion under water than atmospheric corrosion. Underground corrosion may be accelerated by the presence of certain salts or acids in the soil, and by the more ready access of free oxygen either by direct circulation of air or by means of underground waters which have become charged with oxygen and carbonic acid. The corrosive action is greatly increased by a rise in temperature and velocity of water within certain limits and by contact of the metal with any materials which tend to intensify galvanic action, such as cinder or certain kinds of mixed trench fill, or even the heavy mill scale formed in hot finishing of the pipe, which has a strong tendency where firmly attached to localize corrosion and cause pitting. Rust once formed on the surface also acts as an accelerator to a somewhat lesser extent.

From this brief outline of the main factors which tend to influence corrosion it will be seen how important it is to keep all parts of the pipe from contact with wet soil or water through the use of protective coatings of substantial thickness properly applied.

The influence of composition of the metal under most conditions does not seem to have much effect in itself, all other things being equal. Wrought-iron, bessemer-steel, and basic open-hearth steel pipe have been in service thirty years or more, the records of such lines showing failures in some places and practically no corrosion in other places, depending on soil conditions, drainage, and other external factors. So far as the metal itself is concerned the factor of prime importance as affecting initial corrosion seems to be the surface finish, particularly the mill scale, which is decidedly electronegative to iron and therefore is a more or less powerful accelerator of corrosion.

Protection Against Exterior Corrosion

From the foregoing it will be understood that the main object of protective coatings is to exclude water from contact with the metal. Such coatings as are available at present are by their very nature easily damaged and thus rendered practically useless if subject to abrasion after being applied. No coating has yet been found which has any chance of protecting such a material as oil-well casing. Most of what follows is therefore applicable mainly to line pipe or water pipe subjected to underground corrosion.

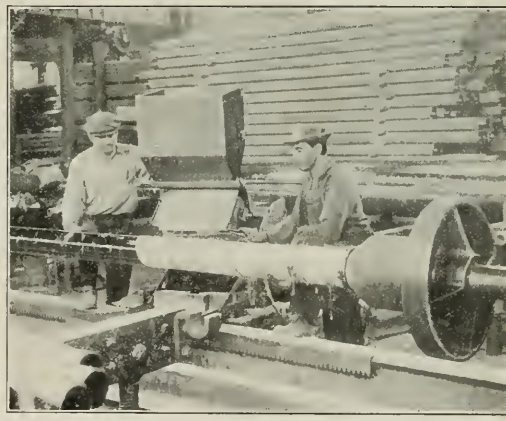

Fig. 1 Machine for Wrapping Pipe Spirally with Fabric after Application of Hot Bituminous Coating

Before any coating is applied in the field all loose rust or scale should be removed and a thin priming coat applied to the clean dry surface after the line is put together and ready to be ditched. When a priming coat is applied at the place of manufacture, it is important that the surface should be cleaned and freshened up before any further protective coating is applied in the field. The subsequent protection needed depends on conditions which should be determined by a careful survey of the nature of the soil and drainage of the territory in which the line is to be laid. In well-drained sand or clay soils a second coat of some reputable pipe compound may be all that is necessary or perhaps one coat may be sufficient, but in wet marshy places, especially where the ground water is corrosive, a much more substantial waterproofing will be necessary. Wherever the ditch can be drained economically, it will of course be of considerable advantage to do so.

The function of the priming coat is principally to afford a strong bond between the thicker protective coating and the metal, and is essential where the subsequent coat is applied hot to the relatively cold metal. The priming coat may consist of coal tar or a pure asphalt dissolved in naphtha or benzol to a thin cosistency. It is of little protective value in itself as is true of paints in general underground. To be of any practical value where underground corrosion is known to occur, a non-porous coating of substantial thickness

[1] Metallurgical Engineer, National Tube Company. Mem. Am.Soc.M.E. Presented at a meeting of the Ontario Section of The American Society of Mechanical Engineers, Toronto, February 2, 1921. Slightly abridged.

[2] Those who want to go into further details of the mechanism of corrosion may consult a paper on Preservation of Hot-Water Pipe, by Speller and Knowland, Trans. A. S. H. & V. Engrs., vol. 24 (1918), p. 217.

is required. The coatings which have given the best service may be classified as follows:

1 Melted bituminous mixtures which can be safely heated to 350–400 deg. fahr. with a melting point of about 150 deg. fahr. may be applied in the field with suitable brushes operated by hand or mechanically. Sometimes a coating of this class is poured over the pipe, the surplus being caught in a strip of canvas about 30 in. wide held by two men, by which means the coating can be worked evenly over the underside of the pipe. In this way with some care and practice a coating of from $^1/_{16}$ to $^1/_4$ in. thick may be applied without much variation in thickness.

The well-known dips applied at the works by manufacturers come under this heading. Most pipe has to stand a wide range of temperature fluctuation enroute to destination, often as much as 100 deg. fahr. If the temperature drops below the brittle point the coating is liable to crack off, and if the solar heat absorbed raises the temperature of the coating above the melting point the mixture runs, in addition to which there is always a certain amount of damage due to abrasion in handling, all of which necessitates careful inspection and attention to repairs. Coal-tar pitch when properly refined makes one of the best preservative coatings, but unfortunately the range between the brittle and melting points of this material rarely exceeds 45 deg. fahr., so that an asphalt blend must be used in most cases where the pipe has to be shipped any distance after coating. The absorption of solar heat may be limited considerably by dusting the surface of the pipe with portland cement or fine white sand. A coating of whitewash applied over the sanded surface has been tried and was found to keep the temperature of the coating down to atmospheric temperature under the July sun.

2 Under some conditions the coating above described may be reinforced with advantage by a strip of fabric 6 or 8 in. wide wound spirally around the pipe while the coating is hot. This is easily done at the mill after the pipe has received the dip coat, by means of a machine designed for the purpose (Fig. 1). The fabric should be dried in vacuum and saturated by passing through a small tank of the asphaltic mixture as it passes on to the pipe. With pipe 12 in. and smaller a saturated fabric in rolls of suitable size would be convenient for this purpose in the field, such as a large-size electric tape, or the fabric may be saturated after application by a final coat of thin consistency. This method of protection has been used for some years and has become standard with one American manufacturer for bell-and-spigot steel water pipe, having been found to give good service.

3 Where the ditch is wet most of the time, especially where stray electric currents are likely to occur in the vicinity of the pipe, provision should be made to keep these stray currents off the pipe by the use of insulated joints or other means.[1] The pipe should then be boxed in as indicated in Fig. 2 after being cleaned and having received the usual priming coat. The pipe is supported underneath every 10 ft. or so on some non-porous insulating material such as a piece of hard-burned sewer pipe or heavy glass about $^3/_4$ in. thick. An asphaltic compound such as Parolite or some similar mixture with a melting point of about 150 deg. fahr. which has been heated so as to run readily is poured in between the pipe and the box on one side. Particular care should be taken that the asphalt passes underneath the pipe without leaving air pockets, which would of course leave an opening for water to penetrate the coating. This coating has been found to be very effective both against corrosion and electrolysis when applied uniformly and not less than $^3/_4$ in. thick.

4 Where corrosive conditions are severe as in marshy places where the water is brackish or acid, a covering of concrete has proved to give the best protection. A mortar of 3 parts sand to 1 of portland cement thoroughly mixed together should be poured between the pipe and the box as in the case of the bituminous coating (see Fig. 2). The pipe should be centered in the box and supported on non-porous material at suitable intervals so that the coating will not be less than 2 in. in thickness for 8- or 12-in. line pipe. The same precautions should be taken as under (3) to avoid air pockets, with careful inspection to avoid leaving any uncoated places. The sideboards may be removed and reused. If this is done a coating of asphalt should be applied to the sides of the concrete before filling in the ditch.

[1] For practical and up-to-date information on this subject, see forthcoming report of the American Committee on Electrolysis which will soon appear under the auspices of the American Institute of Electrical Engineers.

Oil lines protected in this way in brackish water have been free from corrosion for 25 years near the New Jersey coast. Precautions must be taken to guard against or repair cracking from expansion or contraction, or settlement.

Concrete coatings are not proof against electrolysis.

Internal Corrosion of Water Pipe

The corrosion to which iron or steel pipes are subjected from contact with the water on the inside is not so serious as external corrosion; on the other hand, it is somewhat more difficult to protect against.

The principal factors which determine the rate and character of internal corrosion and pitting are:

1 Composition and finish of the metal

2 Composition, temperature and rate of flow of the water.

In the case of corrosion under water, the composition of the metal does not seem to have any marked influence on the character or amount of corrosion. Internal corrosion of cold-water pipes is usually so slow as to be negligible, although in some localities this is not the case. However, the rate of corrosion is usually so slow as to be difficult to determine with cold water, but when the water is heated under pressure the corrosive action is so much accelerated as to make it practicable to compare different materials in the same line and get trustworthy results in a year or two.

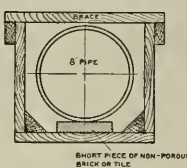

Fig. 2 Section of Wooden Form Used for Application of Asphalt or Concrete Coating

It has often been noticed that internal pitting is much deeper near mill scale where the scale is thick and firmly attached. The reason for this is undoubtedly due to the electronegative character of the scale with respect to iron. Old rust acts somewhat in the same way, but is much less harmful. When the mill scale and rust are removed the tendency to pitting is greatly reduced provided the metal itself is fairly homogeneous and free from strains. It has been clearly demonstrated experimentally that surface finish is much more of a controlling factor in corrosion than any variation in composition of the metal in itself, which is likely to occur, the explanation of this fact being that the external difference of potential due to mill scale and other extraneous matter is much greater than that due to segregation or other irregularities in the metal.

There is a wide difference in the rate of corrosion with different domestic waters at normal temperature. Take, for example, Great Lakes water in comparison with the water supply of most of the New England cities and New York City. An interesting and useful example of corrosion greatly accelerated due to the magnesium salts in the water, is that of the 30-in. steel main to the Coolgardie mining district, Western Australia.[1] A few years after this pipe line was put into use serious corrosion was found both inside and outside. The deepest inside pitting was within a few inches of the lockbar seam where the mill scale had not been broken off in bending the plate. The engineers who investigated this case are of the opinion that had this scale been removed before coating, pitting would not have occurred or would have been greatly limited. The cause of corrosion and means of prevention were investigated by Sir Alexander Binnie, Sons & Deacon, Sir William Ramsay, and Mr. Otto Hehner, who in their joint report, Sept. 30, 1909, recommended that three grains of lime per gallon be added to the water and that the water be deaerated and that precautions be taken to prevent reabsorption of air. The lime treatment was tried first but resulted in a considerable increase in thickness of scale on the interior walls of the pipe. Before the lime treatment was tried a heavy coating of rust and scale had formed in places. The effect of the lime treatment on corrosion of this pipe according to the above report was rather inconclusive and disappointing. Deaerating was then tried. The reports after two years' service

Steam Superheaters: Their Design, Construction, Application and Use

Fundamentals of Design and Materials Used—Characteristics and Details of Locomotive, Marine and Stationary Superheaters—Operating Conditions Where Reciprocating or Rotating Prime Movers Use Superheated Steam—Results Obtained by Using Superheated Steam

By H. B. Oatley,[1] New York, N. Y.

SINCE 1700, when the noted French physicist, Denis Papin, inserted a heated mass of iron in a piston, so that the steam moving the piston might be kept freer from moisture, the advantages of superheated steam, the difficulties of properly designing apparatus for generating it, and the necessity for having prime movers so fitted as to use it effectively, have been known and, as time passed, have been more keenly appreciated by engineers throughout the world.

The present paper will be confined to four phases of the question, namely:

a Fundamentals of design and materials used
b Characteristics and details of locomotive, marine and stationary superheaters
c Operating conditions where reciprocating or rotating prime movers use superheated steam
d Results obtained by using superheated steam.

Design and Materials

Only the tubular form of superheater, and its use as an integrally-built live-gas or waste-gas superheater will be herein discussed.

Important factors in superheater design may be considered under the headings of efficiency, durability, accessibility and safety. A design to be of merit should have a high rating in these four fundamentals.

Efficiency may have three interpretations: efficiency in design, efficiency in operation, and efficiency in return on the investment.

Efficiency in design may be measured in terms of superheater bulk and weight, and by the draft retardation produced by its inter-

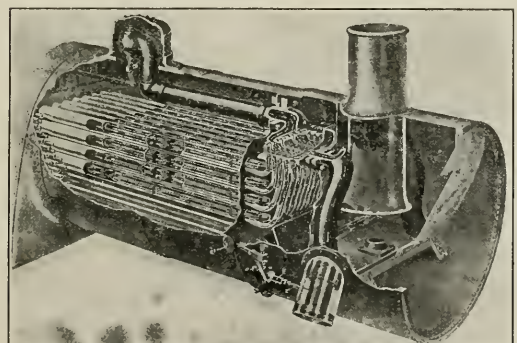

Fig. 1 American Standard Locomotive Superheater, Type "A" Equipment

position in the path of the products of combustion. It is generally true that a superheater of minimum bulk will have a minimum weight and naturally offer a minimum retardation to gases. It also follows that superheaters located in relatively high gas-temperature zones have greater heat-transmitting efficiency; hence, are smaller and more advantageously used. In many cases waste-gas superheaters of not over 50 deg. fahr. capacity have double the weight and bulk of 200-deg. fahr. superheaters of the live-gas type. In the foregoing consideration of elements of design, equal capacities of the superheater should be made the basis of comparison.

Efficiency in operation is affected by the sustained cleanliness of both the gas-touched and steam-touched surfaces, by accessibility for inspection, tightening and repair of the superheater itself, or by the ease with which conditions existing in the vicinity and affecting the performance of the superheater may be corrected.

The character of the outer surface of the superheater pipes, whether smooth or corrugated, controls the ease and thoroughness with which it may be cleaned. It also limits the ability of the soot blower to thoroughly cleanse the superheater from soot and dirt. The predominant use of the smooth surface indicates a general acknowledgment by superheater designers and users of the heavy

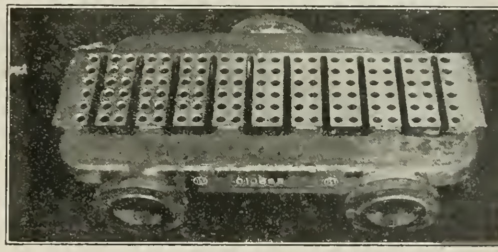

Fig. 2 Preferred Form of Top Header

heat losses resulting from soot-coated superheaters, and the difficulties in cleaning rough surfaces. The importance of the heat losses possible due to soot will be better appreciated when it is realized that it requires five inches of fine asbestos to equal the heat-insulating capacity of one inch of soot.[1] The time required to blow soot from the superheating surface should be as brief as possible, in order to conserve steam.

Efficiency in return on the investment is affected by first cost of the superheater, installation expense and maintenance charges compared with the financial gain obtained. Generally speaking, fuel economy is first considered among the advantages of superheating, although in many cases, particularly in railway and marine service, the results of large water economy aggregate a considerable item. Reduced boiler maintenance, because of the smaller quantity of fuel burned, and water evaporated, per horsepower-hour frequently appears as a credit due the superheater.

Durability is measured by the life of the superheater parts, and by the period elapsing between repair periods. This feature is affected by service conditions, and by the position of the superheater with respect to the path of the gases. In superheaters located where soot accumulation is rapid and where moisture may reach it, the soot will produce greater deterioration than where the superheater elements are subjected to live gases. This to some extent may explain the attempt to protect, by cast or malleable iron, steel unit pipes of waste-gas superheaters. The deposit of soot is naturally less where gas velocities are high, and explains the preference of the majority of designers for live-gas superheaters, and for the high gas velocities that are obtainable with such designs.

Accessibility should embrace "getatability," not only of the superheater but of adjacent parts of the boiler and other details. A minimum number of steam joints in the superheater, and their location at a point where inspection may be made without shutting

[1] Chief Engineer, Locomotive Superheater Co. Mem. Am.Soc.M.E

Condensed from a paper presented at a meeting of the Eastern New York Section of The American Society of Mechanical Engineers, Schenectady, N. Y., January 13, 1921.

[1] *Paper Industry*, November 1920, p. 1187.

down the boiler, or involving excessive labor and trouble in making such inspection, are to be considered under this head.

Safety rarely becomes a problem in superheater design, inasmuch as the size of superheater parts is small in comparison with boiler drums and also because the stored energy in the entire superheater is relatively small. Furthermore, the factor of safety in both units and headers, due to the consideration of durability, and the small sizes of parts, is relatively high. In case of failure of a unit, damage to property is negligible and injury to the operating personnel practically unknown. A representative of one of the largest insurance companies recently made the statement before a board of boiler inspectors that his company, and he believed that other

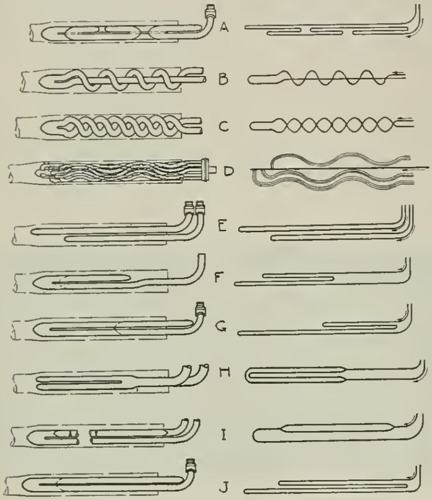

FIG. 3 TYPES OF SUPERHEATER UNITS

companies, had not received a single claim in connection with a superheater failure.

CHARACTERISTICS AND DETAILS

It may not be realized that the locomotive superheaters in use in this country alone have an aggregate horse power of over 60,000,000. All of these superheaters have tubular structure, and are of

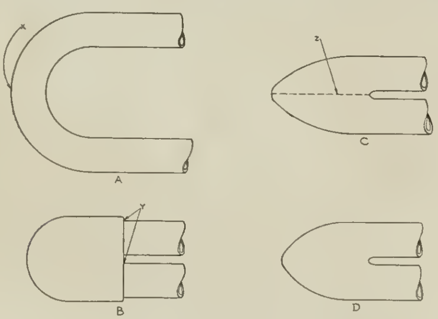

FIG. 4 METHODS OF CONNECTING TWO PARALLEL PORTIONS OF A SUPERHEATER UNIT

the bare fire-tube live-gas type. What is true in the United States as to type and structure of superheater, is true in other countries of the world where steam locomotives are in use.

The limitations imposed in the design of a superheater for a locomotive boiler are, in the author's opinion, more severe than for any other use. Space is restricted, weight conditions important and the requirements for high degrees of superheat very pronounced. The compactness of the boiler provides severe operating conditions for the superheater, because of the quality of the steam delivered to it. Steam velocities existing within the superheater units, gas velocities passing over the outer surface of the units and the necessity for strong and rugged structure to withstand the severe vibratory conditions encountered while the locomotive is running, require great care in the design and construction of the equipment.

The superheaters installed in more than half of the steam locomotives in this country weigh from 3.0 to 4.0 lb. per maximum cylinder horsepower of the engine. These figures are interesting, particularly in comparison with the running-order weight of engine per maximum cylinder horsepower, which, on the modern locomotive, ranges between 115 lb. and 160 lb. The figures in Table 1 show these ratios for the United States Railway Administration standard engines built during the war.

TABLE 1 WEIGHTS OF SUPERHEATER AND ENGINE PER MAXIMUM CYLINDER HORSEPOWER OF U.S.R.A. STANDARD ENGINES BUILT DURING THE WAR

Type of engine	*A* Weight of superheater, lb.	*B* Max. cyl. hp.	$\frac{A}{B}$	*C* Weight of engine only, lb.	$\frac{C}{B}$
060-A	4326	1397	3.10	165000	118.2
080-A	6475	1822	3.56	214000	117.5
282-A Light	8432	2252	3.75	290800	129.2
282-B Heavy	9451	2308	4.09	325000	141.0
2102-A Light	10016	2428	4.13	352000	145.2
2102-B Heavy	11023	2850	3.87	380000	133.4
462-A Light	7669	2082	3.68	277000	133.0
462-B Heavy	8432	2428	3.47	306000	126.0
482-A Light	8931	2428	3.68	327000	134.8
482-B Heavy	10016	2610	3.84	352000	135.0
2662-B	11386	2810	4.05	448000	159.7
2882-B	13554	3720	3.64	531000	142.8
		Average =	3.74		134.6

The steam velocity in units of locomotive superheaters frequently is in excess of 12,000 ft. per min. This may be startling to many power-plant engineers who consider 6000 to 8000 ft. per minute as the upper limit of steam velocities in pipe lines.

Gas velocities through the flues of locomotive boilers, as in stationary power plants, vary through a wide range, and it is not unusual to find velocities of 8500 ft. per min., or more than 90 m.p.h., when locomotives are working to their capacity.

Fig. 1 shows the American standard locomotive superheater termed the type "A" equipment. Its general characteristics are believed to be well known and the description will be centered on the question of headers and units.

Fig. 2 shows the preferred form of top header, termed the "modified through-bolt" design, which is fitted in nearly one-half of the superheater locomotives in this country. This header is made of high-grade cast iron, is rather intricate in coring and good foundry

FIG. 5 STEPS IN THE FORGING OF SUPERHEATER RETURN BENDS

practice is required in order that a satisfactory header may be obtained. Alternate cross-passages carry saturated steam and superheated steam. Expansion is provided, as well be noted from the coring which separates adjacent fingers, without setting up excessive stress in the header. This construction at the same time reduces to a practical minimum the amount of wall surface subjected to different qualities of steam.

There have been numerous forms of header, in which cast-steel

and steel-plate construction have been used. Experience has demonstrated, however, that there is no necessity for using cast steel.

Units in locomotive superheaters are universally of cold-drawn seamless steel tubing and range from $1^3/_8$ in. to $1^5/_8$ in. outside diameter, with the $1^1/_2$-in. size as the most generally used size.

Units designed for use in fire tubes have undergone a most interesting development. Fig. 3 illustrates a few forms, all applicable to a fire-tube superheater, and some possessing features applying equally to a water-tube boiler installation.

In summing up the question of superheater unit, it is considered that unit J, which is really a world-standard form, represents the highest average of any thus far developed, particularly when considered on the basis of—

a Efficiency in the abstraction of heat from the gases
b Thorough mixing and *uniform* superheating of the steam
c Better equalization in the area of gas passage and more constant gas velocity
d Maximum superheating surface
e Minimum resistance to flow of gases when (*c*) and (*d*) are considered
f Less opportunity for deposit of soot and cinders by maintaining relatively high gas velocity through length of flue
g Cost.

Units H and I are forms not thus far used, but experiment has demonstrated that they will meet, from an efficiency standpoint, all of the advantageous features of the standard unit J and from a practical operating standpoint would not differ appreciably from the standard unit. They would be more expensive to manufacture, and under present conditions are, therefore, not generally preferred.

In the design and installation of units two important features are (*a*) return bends and (*b*) the jointing of units to the headers. Fig. 4 represents the development in connecting two parallel portions of a superheater unit.

Sketch A is the simplest form and is merely a pipe bent into a "U," or hairpin, form. Diameter of tube and distance between the two pipes have naturally minimum limits if distortion in the bent portion of the pipe at X is to be avoided. For fire-tube superheaters, where a close spacing is essential, bending of the pipe in this way is obviously prevented.

Form B shows two pipes fitted to a return bend. The return bend as used is almost always of cast steel, and the pipes are threaded into it. In designs where expansion stresses are excessive, it is necessary to acetylene or electric weld the joint Y between the return bend and the pipe, in order to insure permanent steam-tightness.

Increasing demands in capacity, particularly for locomotive and marine installations, require a minimum of obstruction in the flue and, for a number of years, pipes have been joined by forming their ends, and welding the two pipes together as shown at C, Fig. 4, the welded joint being at the point Z. The extremely severe service conditions of a superheater have demonstrated that the durability of electric or acetylene welds is not sufficient to insure requisite life and freedom from possible steam leakage. Long experiment and persistent efforts to develop practically a perfect bend resulted in the form now in world-wide use, and termed the "forged" return bend. In appearance it is as shown in sketch D. Particular points of advantage are uniformity in the character of the metal, freedom from any roughness or obstruction, either within or without the return bend, and a strength which is never less than that of the pipes of the unit from which the return bend is made.

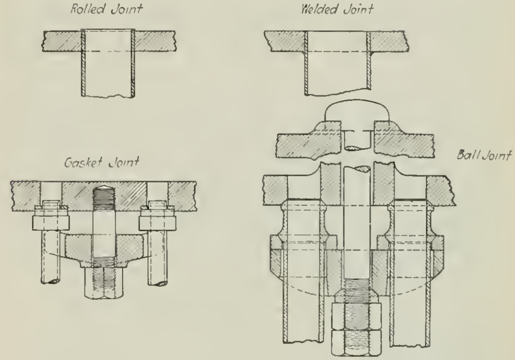

Fig. 6 Methods of Connecting Superheater Units to the Headers

Fig. 5 shows the steps in the process of forging this return bend. It is proper to emphasize that it is made *from the pipe* without the addition of any other material. The finished unit therefore becomes practically a continuous pipe without other than forged welds.

The jointing, or connection, of superheater units to the headers, or collector castings, is another detail which has passed through numerous stages of development. Methods of connecting these two superheater parts may be classified as permanent and detachable, and are shown in Fig. 6. The term "permanent" as here used covers joints which are welded, or are made by rolling the pipe in the header, either method requiring considerable work and time for removal.

Where pipes are welded to the header, actual breaking of metal

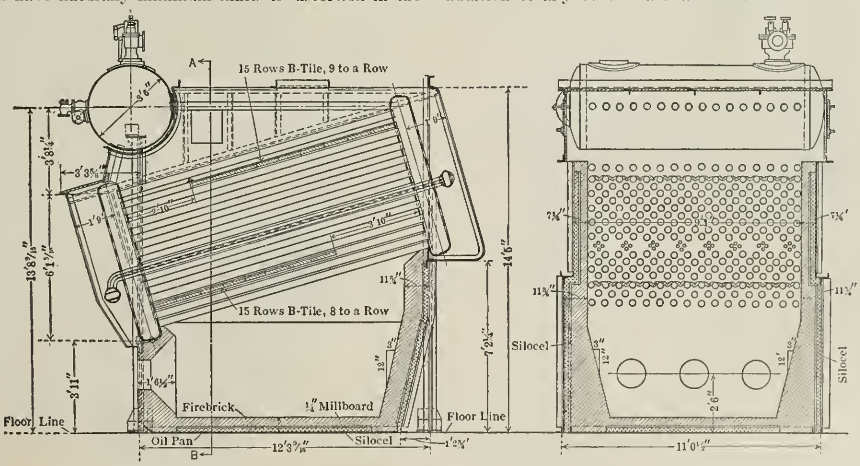

Fig. 7 Setting for Heine Boiler Built for the Emergency Fleet Corporation

is necessary in order to remove a unit. Where pipes are rolled into a header, in a manner similar to the setting of a tube in a boiler, it is necessary to remove a handhole plate, or a plug, and then to crimp the expanded end of the unit pipe and drive it out of the header. It is, of course, possible to cut off the unit outside of the header, and to remove the cut-off portion separately. This is perhaps better practice, as it makes available, for later attaching the unit to the header, material which has not been stressed and fatigued by previous rolling and expanding. Obviously, to cut

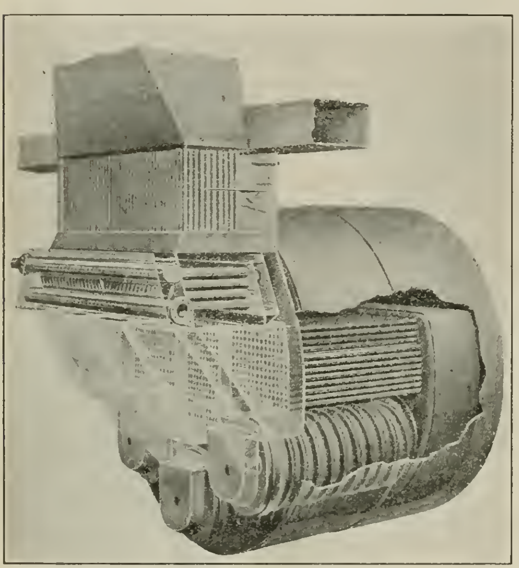

Fig. 8 Foster Superheater in Scotch Marine Boiler Utilizing Waste Heat

off the end of a unit, applicable to fire-tube boilers, makes necessary welding on a short piece of pipe, or rebending the unit, in order that it may reach the header, and at the same time occupy its proper position in the boiler tube. Either method involves considerable time and expense.

Disconnectable, or detachable, unit ends have been in almost universal use for locomotive and marine superheaters, and to a considerable extent in stationary practice. The advantages of disconnectable units are obvious and recognized fully in all lines of superheater use.

Fig. 6 shows both the gasket joint and the ball joint, and quite well illustrates the forms used throughout the world.

The gasket joint is to be preferred where the smaller diameter and more flexible superheater pipes are used. With small pipes the joint is easily drawn up normal to the seat and, because of the flexibility of the pipe, expansion and vibration cannot produce leakage.

In the locomotive field where unit pipes are of larger diameter and consequently more rigid, it has been found of decided practical advantage to use a metal-to-metal spherical joint. This form has been developed in the United States and its adoption has followed in a number of other countries.

Some Considerations in Marine Practice

In marine practice fire- and water-tube boilers are met with. The former have, for years, been used almost exclusively in merchant ships, while the latter, for a decade or more, have been practically a standard in naval construction. During, and since, the war, water-tube boilers have had greater application to passenger and cargo vessels.

Fig. 7 shows a Heine boiler as fitted in a number of war-built American vessels. The unit pipes are parallel to the water tubes, running through both water legs, and being attached, front and back, to the headers by rolled joints. The use of this type of equipment has thus far been confined to American vessels built within the past four years.

Fig. 8 illustrates the Power Specialty Company's waste-gas superheater, which was applied to both Scotch fire-tube and water-tube boilers fitted in some vessels built by the Emergency Fleet Corporation. The units in this design are of the covered type with extended surface. The covering is of cast or malleable iron slipped over the steel superheating tube. The units are attached to the header, as well as to the return bend, by rolled joints with handholes and covering plates opposite the pipe opening.

Fig. 9 shows the Locomotive Superheater Company's type M apparatus, the units being of the bare-tube type with forged return bends, and are connected to the headers by the recess gasket joint previously referred to. With this method of joining no handholes or handhole covers are required.

Fig. 10 is a picture of a complete superheater withdrawn from a Scotch boiler. The headers, to which the units are attached, are made of either high-grade cast iron, cast steel or forged steel, as may be desired, and as may be deemed acceptable by the classification societies in the countries in which the ship is to be built. Attention is invited to the chief difference between the type M marine superheater, and the type A-locomotive superheater. In the marine design, pipes of from $^5/_8$ in. to 1 in. outside diameter are used, and only one loop of the unit occupies a flue. In the locomotive type two loops of a unit occupy the same flue. In the marine type there may be from two to six loops in as many flues, depending on the proportions of the boiler and the degree of superheat specified.

In type M installations no change is usually made in the diameter

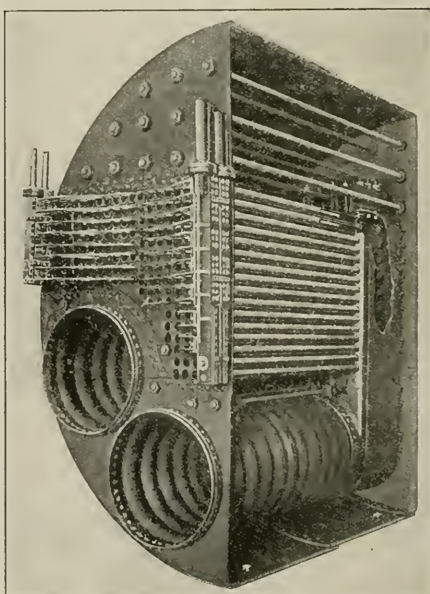

Fig. 9 Locomotive Superheater Co.'s Type "M" Superheater

of the tubes in the boiler from what would be fitted for saturated-steam operation. It is possible to do this because—

a The tubes in Scotch marine boilers have a relatively low ratio of length divided by internal area, and

b The gas area may be made more favorable, because of the flexibility permitted by the superheater design.

The question is many times asked how it is possible to insert superheater units in the tubes of Scotch boilers without retarding the draft. The explanation is not difficult to understand, when it

is realized that a reduction in fuel per hour of from 10 to 18 per cent is made possible through utilizing highly superheated steam. This means that the quantity of gas passing through the tubes is reduced in the same proportion as the quantity of fuel burned per hour, and that therefore a smaller area is sufficient if the same gas velocities are obtained. The obstruction caused by reduction in gas area, resulting from the insertion of the superheater units, is calculated in the design and in determining the diameter of the superheater pipe. The number of boiler tubes receiving the units, as well as the length of the unit, are varied to meet the conditions. It is also interesting to point out that the resistance of the gases passing the unit has, by careful test, been shown to be not more than the resistance encountered in passing a retarder having one turn. The use of retarders in marine practice is quite general, and they are frequently given from one and one-half to three turns. If a boiler fitted with retarders of two turns should be considered, it will be quite possible to remove the retarders, apply superheaters, obtain the fuel economies consistent with the type of prime mover used and, without increasing the air pressure from the fan, to burn, if occasion requires, a larger amount of fuel per hour and, assuming that the prime movers in the ship are suited, to obtain a very much greater indicated- or shaft-horsepower output.

The superheater installation in the S. S. *Cuba*, the first passenger vessel under the American flag to receive turbo-electric propelling equipment and to use high degrees of superheat, may illustrate more fully the points referred to. There were originally four Scotch boilers supplying saturated steam to triple-expansion engines of 2400 i.hp. These boilers were, if anything, small for the power to be developed. The space available in this vessel for the boiler room could not be increased without prohibitive expense and cutting down on the space usable for other purposes. It was desired to provide 3000 shaft hp. in the new installation of propelling equipment, and the question immediately arose as to whether the boilers would be adequate. The substitution of turbines for reciprocating engines naturally effected an economy in steam, but without increasing boiler efficiency. The installation of fire-tube superheaters has not only increased the boiler efficiency, but has provided a more efficient working medium. The net result being that 3000 shaft hp. is being supplied from the original boilers.

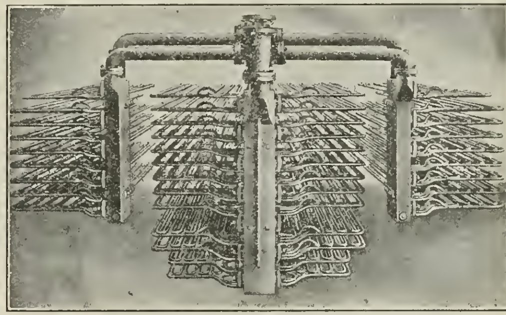

Fig. 10 Complete Superheater Withdrawn from a Scotch Boiler and Power Co. of New York

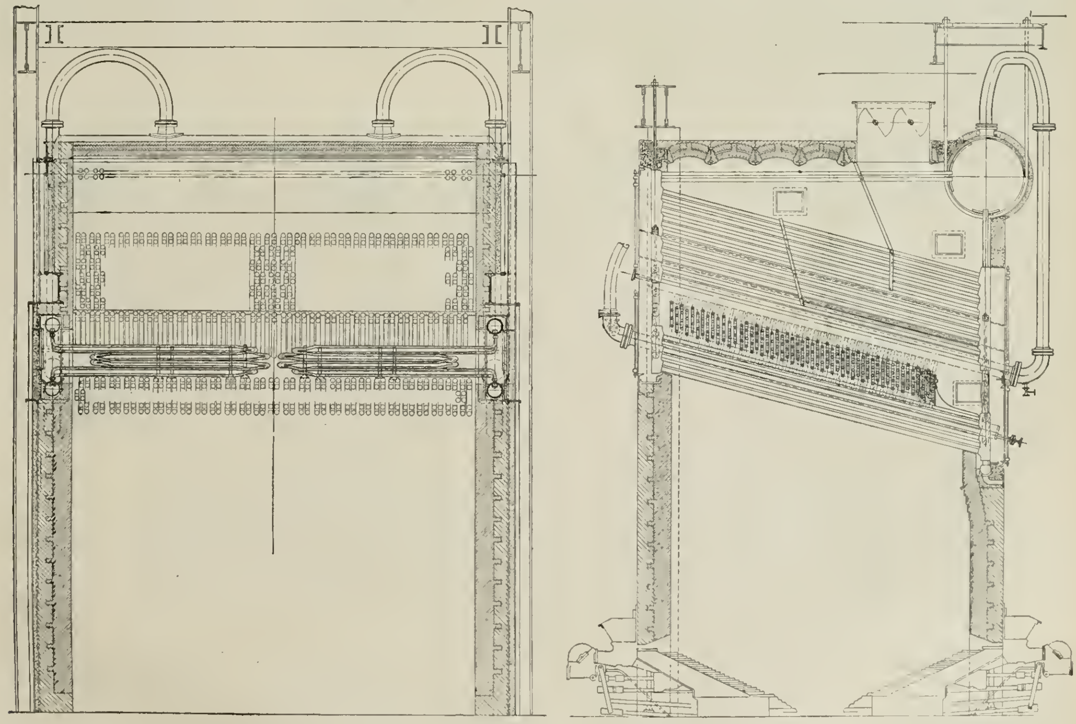

Fig. 11 Superheater for One of Twelve 1090-Hp. Water-Tube Boilers for the New Hell Gate Plant of the United Electric Light and Power Co. of New York

In the marine field, the adoption of superheaters has gone forward more slowly due to a number of causes which, previous to the world war, made the question of relatively less importance. American ships were not to any extent then in competition with vessels under foreign flags and fuel costs were comparatively insignificant. Today this condition does not exist. Our war-built merchant fleet, which will be the nucleus of a greater American merchant marine, is now in competition on all seven seas against vessels flying other flags, and this competition necessitates the most careful study of operating costs. More than 75 per cent of the steam-driven merchant ships built abroad since the war have been fitted with super-

heaters, and fuel economies of from 12 to 18 per cent, depending on the type of propelling equipment, are being obtained by foreign operators. Fuel costs where they now are, or where they may be in the future, are compelling reasons why American marine engineers must adopt superheated steam, and other means of reducing fuel costs, or face handicaps which will militate against American success.

Many of those opposed to such betterment in operating conditions have contended that the personnel on American ships is unable to handle superheaters and equipment using superheated steam. To make such contention is a slander on American ability to do aboard ship what is being done in our power plants, and on locomotives.

It is doubtful whether our war-built vessels can be made quite as effective in the use of fuel as prewar construction. This statement is made without the intention of criticizing the colossal task which the Emergency Fleet Corporation and Shipping Board performed from the date of its organization up to the armistice. For failure, however, to change their viewpoint subsequent to November 11, 1918, and for failure to make the changes which were possible and necessary in order that post-war construction should have high operating efficiency, considerable criticism may be given fairly to the officials in charge. It is only within the past nine or twelve months that a few ships have been so revised as to produce operating economies which will give them a more nearly even chance with foreign-operated vessels. The S.S. *Eclipse* may be cited as one instance of this character.

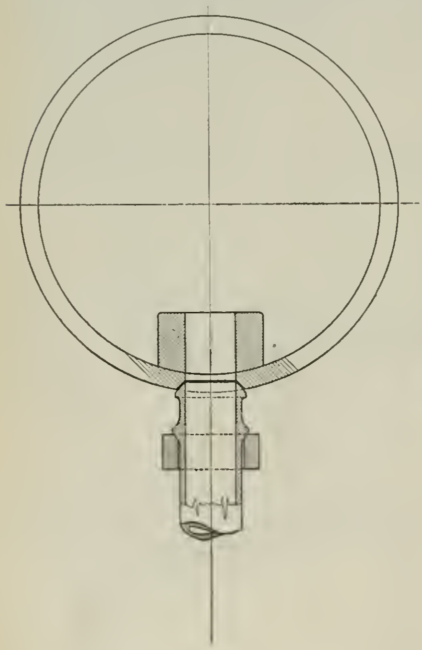

Fig. 12 Inside Bar Circular-Section Header

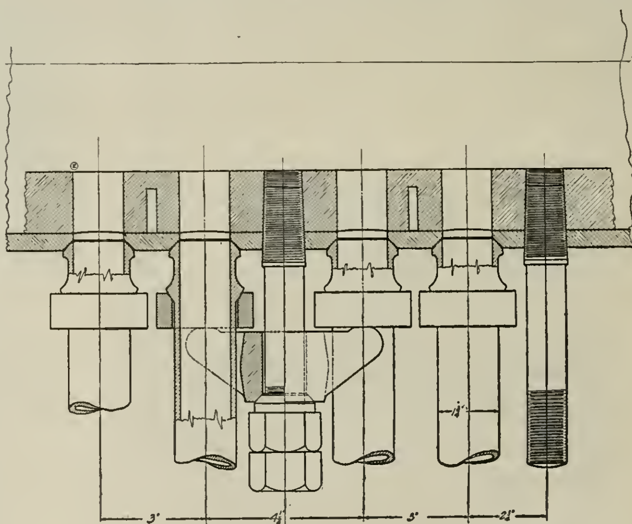

The original decision of the Emergency Fleet Corporation at the beginning of their program called for low-capacity superheaters giving not over 50 or 75 deg. of superheat. It was believed that this would be adequate to provide protection for turbines. Had the specified amount of superheat been obtainable under the severe conditions existing at sea, such a program would have been correct and justified. The many instances of turbine blades cut by water, after but a few thousand miles of operation, demonstrated that low-capacity superheaters, under the conditions stated, failed to provide the protection which was necessary. It is difficult to understand why the known successful means of fuel economy, all the data for which were in the possession of the Emergency Fleet Corporation in 1917, have not been utilized in the post-armistice program. Not only would the protection to turbines have been assured, but economy in fuel and increased cargo space, vital as they are, would have been assured. The tonnage of iron and steel, critical as it is, would have been reduced 50 per cent, so far as the metal entering into the construction of superheaters was concerned.

A Late Example in the Stationary Field

The boiler shown in Fig. 11 is now being built by the Springfield Boiler Company for the new Hell Gate plant of the United Electric Light and Power Company of New York. The first installation will consist of twelve boilers. Space is provided for twelve more. When this plant is finished it will probably be the largest power plant in the world. The boilers are equipped with stokers on both ends and an adequate amount of combustion space is provided to make them capable to work at very high rating. The leading feature of this installation is the location of the superheater. Up to date all superheaters installed in this type of boiler have been arranged with the headers inside of the boiler, and with units located between the first and second pass, extending parallel to the boiler tubes. This new superheater arrangement is different from any other design in this country. The superheater is located in the first pass between the sixth and seventh row of tubes. The space is thus selected to protect the elements from too high temperature and at the same time to secure the high superheat specified with a minimum amount of tubing, and as little obstruction to the flow of the gases as possible.

The superheater is designed to deliver about 200 deg. of superheat at approximately 200 per cent rating, with maximum pressure drop of 10 lb. at 300 per cent rating. The design provides for two sets of elements and two sets of headers located in the side wall on each side of the boiler. The headers are supported on steelwork. They are free to expand and contract in all directions, and all joints between header and units can be inspected from the outside of the boiler by merely removing the access doors in front of them.

The elements are fastened to the headers by means of a detachable ball joint. They are equipped with forged return bends. Every unit can be removed from the boiler should necessity occur, without entering the boiler setting, and without disturbing any other portion of the boiler, other than the opening of an access door. Another feature of this superheater is the number of joints in the headers. There are only two joints for every 60 ft. of tubing, and there are only 204 steamtight joints in the entire superheater, as compared with other superheater designs which would have at least four times as many joints, including handholes.

Superheater headers are, in stationary and marine service, sometimes cylindrical in section, sometimes flattened on opposite sides, and in some designs are rectangular or square in section. The material is open-hearth steel.

Fig. 12 illustrates an "inside bar" circular-section header, and shows units connected to the header in a manner similar to the practice in use on all American locomotive superheaters. The units in stationary practice are of either the bare- or covered-tube type, the former predominating, although not to the extent found in railway and marine installations

Fig. 13 shows, in correct relation, sections and side elevations of various styles of units found in stationary superheaters. Relative bulk and weight may be easily compared.

The use of cores in superheater units is decreasing, for the reason that the practical disadvantages offset the theoretical advantages, particularly under bad water conditions. The second and third units of Fig. 13 have frequently been fitted with cores.

TABLE 2 TESTS MADE UNDER ACTUAL OPERATING CONDITIONS

(Machine shop only under constant load conditions at night. Tests made about two weeks apart with flues and approximately the same condition.)

	Duration of Test—4 hours each			
	Saturated steam	Superheated steam	Increase per cent	Decrease per cent
Total coal consumed, lb	9316	6827	...	26.7
Steam consumption, lb. of water	57500	46000	...	20.0
Avg. steam pressure of boilers, lb	118.0	115.0	...	2.5
Avg. load on Corliss engine, i.hp	43.0	43.6	1.4	..
Avg. load on Woodmill engine, i.hp	43.2	42.8	...	0.9
Avg. load on electric generator, kw	56.7	56.8	0.2	..
Revolutions of air compressor, total	26590	26630	0.1	..
Boiler hp. developed	386	336	...	12.9
Per cent rated capacity developed	107.0	93.3	...	..
Temp. of feedwater, deg. fahr	212	207	...	2.4
Heat value of 1 lb. coal, B.t.u	13510	13190	...	2.4
Degrees superheat, main header	...	163	...	..

Operating Conditions

To go into the details of operating conditions would require more space than is available, and only a few of the more important factors will be referred to.

Increased steam temperature makes necessary provision for greater expansion of pipe lines, expansion joints, etc., than where saturated steam is used. In installing superheaters in existing plants, it is therefore necessary to determine what expansion is

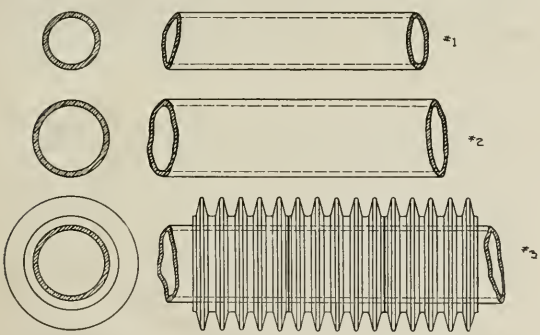

Fig. 13 Styles of Units Found in Stationary Superheaters

provided for, and if not adequate, provision must be made, or pipe-line difficulties will ensue.

Where reciprocating engines are using superheated steam, the valves must be of proper design and material, and suitable lubricating conditions must be provided by using oil of proper quality.

When turbines are to change from saturated to superheated steam, it is necessary to know that the turbine design is suitable, and what degree of superheat may be used without distress.

Results Obtained

In locomotives, upward of 20 per cent in fuel economy is believed conservative as applying to the 33,000 locomotives, with high-degree superheaters now operating on the United States railroads. Road tests of locomotives are more difficult to carry out with the accuracy obtainable from stationary plants, but comparative results, on which conclusions may be reached, have fortunately been available through testing plants of the Pennsylvania R. R., Purdue University and University of Illinois.

Fig. 14 shows indicator cards obtained from the Pennsylvania test results, which indicate the steam economy for equal horsepower, and Fig. 15 shows the increased horsepower for comparable rates of evaporation. The steam economy shown is $30^1/_4$ per cent, and the increase in horsepower for a given evaporation is 45.1 per cent.

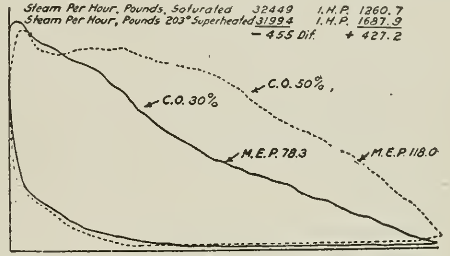

Fig. 14 Indicator Cards Obtained in Pennsylvania Railroad Tests, Showing Steam Economy for Equal Horsepower

In marine service interesting data have been collected, generally from the owners, for over fifty vessels ranging from 2800 to 16,000 deadweight tons cargo capacity, some driven with reciprocating engines, some with geared turbines, and some having turbo-electric drive. Thirty-eight of these ships provided with superheaters averaged a coal consumption of 3.3 lb. per 100 dead-

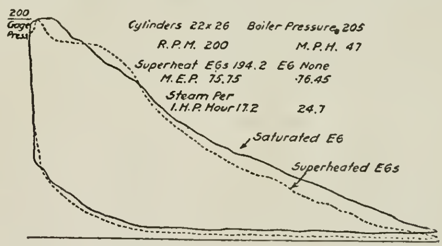

Fig. 15 Indicator Cards Obtained in Pennsylvania Railroad Tests, Showing Increased Horsepower for Comparable Rates of Evaporation

weight ton-miles, while for fifteen not so equipped the fuel consumption averaged 5.28 lb. per 100 deadweight ton-miles. Comment on these figures would be superfluous.

The results obtained by using superheated steam in stationary power plants are more numerous, and very complete accounts of carefully conducted tests have filled the pages of the technical papers for a number of years.

Table 2 is believed to be of more than ordinary interest as it indicates the savings obtained by superheater installation in a railway power plant. As might be expected, fuel economies are high due to the fact that the character of work performed by the steam in plants of this kind is varied, and, of necessity, inefficient at best. It is well known that economies obtainable from superheated steam are more pronounced when the steam is originally used less effectively, and fuel savings for a given degree of superheat are greater for simple and compound engines and less for turbines and triple-expansion condensing engines.

In the railway field, where its adoption and extension has been most rapid and complete, there is a strong desire to go to even higher degrees of superheat than formerly, and hundreds of our locomotives are operating with steam at temperatures beyond any ordinarily found in either stationary or marine service.

The belief of many engineers, strengthened by considerable study of the problem, is that steam of 800 deg. fahr. temperature is adaptable for general use, and that the results will be entirely justified and will prove gratifying to owners and operators of such plants.

The Possibility of Improved Methods of Rolling Sheet Steel

By SUMNER B. ELY,[1] PITTSBURGH, PA.

PROBABLY the first iron plates were made by hammering and must indeed have been a crude production. About 1725–1730, however, rolls seem to have come into use, although it was a number of years later before anything resembling a thin sheet was made. Yet from that day to the present time the same general type of machinery has been used for rolling sheet steel. To be sure, our sheet mills of today compared with the early ones would appear giants in size and strength, yet after all what real difference is there except this increase of size and strength? We have no continuous sheet mills, we do not even use roller-driven tables, automatic guides, etc., and practically everything is done by hand.

This statement may need a little qualification. Occasionally we do come across some small devices in use. Such, for instance, as a hinged or pivoted table to assist the catcher returning the pack over the top of the rolls to the roller. This particular device does not save any labor, in the sense of fewer men being employed; it is merely a help to the catcher. Some devices, such as shifting tables, and auxiliary attachments to cold rolls, may have a tendency to cut down the labor force; but after all such small helps as these are not real changes in the machinery of sheet rolling, and furthermore are far from being universally used.

It would seem, however, as if some device might be gotten up to cut down the number of men needed about a sheet mill. A mechanical catcher, for example, which would automatically catch the pack of sheets as it came through the rolls, lift it up and return it to the roller again. Such a device would seem to be a mechanical possibility and probably could be made to work successfully, but the amount of saving it would effect has apparently not been sufficient to act as a real incentive.

Importance of Proper Heating in Sheet-Steel Rolling

In the manufacture of heavier steel products the temperatures to which they are heated are high, comparatively, and there is some latitude; but with sheet steel the heat must be just right. Even starting with the bar, say, as it comes from the furnace for the first pass in the mill, if it is too cold the scale will not be lifted and this scale rolls into the sheets, making rough surfaces and causing them to stick together when later they are rolled in packs. If the sheet mill could receive only bars that were perfectly clean, no harm might be done even if the heat was a little too cold; but all commercial bars carry scale and this, of course, must be taken into account.

However, if instead of the bar coming too cold from the pair furnace, it is a little too hot, then there is still worse trouble; for the large sheet rolls will get hotter than the roller anticipated, will expand and the line of contact between them will not be correct; and in addition, as the bar is too hot it will be softer than it should be, and will not spring the rolls the desired amount. The consequence of this is that the bar when worked down on the chill rolls will produce a sheet round on the back end, that is, thinner in the center than at the sides; whereas, probably the bar that preceded it had the proper temperature and produced a sheet that was not long in the center, but long on each side, having what the roller calls "horns." A round-end sheet indicates that the rolls are "full" in the middle and horns show that the rolls are "hollow." Now when a circular-end sheet is placed on top of a horned sheet and the two are reheated and put into the rolls together, the pack will either pinch or run off at the back end, that is, the sheets will spread one from another on the back end of the pack, due to the uneven drawing.

And even if the roller by great care and judgment in adjusting the draft screw is able to prevent a pinch, the scale which is produced by excessive heating will only lift in spots, sinking into the sheets and causing the pack to stick together in patches, so that the sheets cannot be pried apart without tearing.

Every one familiar with sheet rolling realizes that the rolls must be kept at the proper heat so that they will maintain the proper shape to successfully roll such a thin product. A roller may (probably unconsciously) count on a certain spring to a stand of rolls and by trial find the proper heat to go with it, so as to keep the shape of his rolls right; and he will watch carefully the size of the horns on each sheet as this is an indication of the shape of the mill. He knows that if he rolls too fast—does not allow time enough between passes—his rolls will lose their shape. Neither must he roll too slow. Again, sheets always entered at the same place on the roll may cause trouble. He must constantly watch and guard against such things as cold drafts of air blowing on the rolls, in fact, anything that will in any way effect the temperature of the roll.

Of late years some of these difficulties have been helped by burning gas against the rolls to expand them when not in operation or by blowing steam on working rolls in order to keep down the expansion.

Roll-Neck Friction an Important Factor

Another most important factor is the roll-neck friction and it is not always appreciated how much this amounts to. For example, when finishing a pack if one neck of a roll be greased (with hot neck grease) without greasing the other, the pack will always draw a long horn next to the neck that is dry. The reason is that the friction on the ungreased neck is greater and consequently heats and expands the roll on that side. The author has reason to think that anywhere from 60 to 90 per cent of the power required is used in overcoming roll-neck friction, although there are no definite figures to go on. This is one of the most important things in roll design and yet there is no scientific information available on the subject; if there were it might lead to some radical changes.

Prof. W. Trinks of the Carnegie Institute of Technology has plans for building an experimental rolling mill which is arranged so that each factor entering into the problem of rolling can be controlled; and it is hoped that such a mill will be installed, for there is great need of definite figures in connection with all steel rolling generally. The apparatus devised for the purpose of determining roll pressures and spreading forces in this mill was described at length in Mechanical Engineering of January 1920 (pp. 11–13), by W. B. Skinkle, at that time Director of the Bureau of Rolling Mill Research of the Carnegie Institute of Technology.

On hot-roll sheet mills at work a blue or indigo color is often observable and this will correspond to a temperature of about 550 deg. fahr. This temperature will often run higher, although when reaching 750 deg., showing a gray, the roll is liable to break shortly afterward. In a totally dark room probably 900 deg. fahr. would give the roll a perceptible red color. Naturally the roll is hotter in the center than at the ends and the necks are still cooler; for although grease is often seen burning on the neck, yet the temperature at which it burns is generally lower than the temperature of the roll as indicated by its color.

In the history of sheet rolling there has been a tendency to continually increase the diameter of the rolls, until today sheet rolls of 30 in. are seen, and the author understands rolls as large as 32 in. have been used. The larger the roll the more tonnage can be turned out, as the large roll does not change its temperature as readily as a small one. There is evidently a limit to the size however (aside from practical considerations of handling such heavy rolls), for the larger the roll the more the radiating surface to cause cooling. The fact that the volume varies as the cube and the

---

[1] Professor of Commercial Engineering, Carnegie Institute of Technology; formerly Chief Engineer, American Sheet and Tin Plate Co. Mem. Am.Soc.M.E.

Condensed from a paper presented at a joint meeting of the Pittsburgh Section of The American Society of Mechanical Engineers and the Engineers' Society of Western Pennsylvania, April 26, 1921.

surface only as the square of the diameter, has only an indirect relation to this problem of cooling. It is also to be borne in mind that the larger curvature will not draw the steel as much for the same total pressure.

As far as the breakage of rolls is concerned, this is apparently due to unequal expansion, and not to the stress of rolling—as evidenced by the fact that rolls sometimes break when the roll is standing still, the roll train perhaps having been stopped for a few moments during the working period.

The Possibility of a Continuous Sheet Mill

Considering now the possibility of a continuous sheet mill, it will be remembered that about fourteen years ago the U. S. Steel Corporation spent a very large sum of money at South Sharon, Pa., and installed a continuous sheet mill which consisted of a series of stands of ordinary two-high rolls in tandem; the sheet passing through one stand after another, never being in two stands at the same time; and the sheets were automatically doubled and matched together in special devices at certain points in the train. After a most thorough trial, however, the mill was dismantled and the ordinary method of sheet rolling installed.

This is a convincing and definite proof of the great difficulties of sheet manufacture by using our present roll stands in a continuous train. Aside from any other question, the difficulty of keeping so many different rolls in a like expanded condition and shape seems insurmountable. The present method of using gas and steam on rolls which was not known at that time, might have aided a little; but something much more certain than this must be devised if light gages are to be rolled in this manner. Possibly the heavier gages, 10 and 12, say, could be made in this way; but we already have satisfactory mills of a different type for this purpose and we would be no further along toward automatically rolling light-gage steel.

Some method of absolutely heating the steel to a definite temperature, possibly some form of electric furnace, and some way of keeping the shape of the roll, must be devised. Rolls have been cast with holes through the centers and steam introduced or gas burned inside them; but they have been found inadequate to hold their shape and stand up to the service. The practice already mentioned of using gas and steam on the surface of the rolls is more satisfactory. Perhaps some day rolls will be placed inside a constant-temperature furnace; but what would be done about the bearings and other details is a question which as yet has not been answered.

A Successful Austrian Continuous Sheet Mill

Some twelve or more years ago the author visited a continuous sheet mill in the town of Teplitz in Northern Austria. This is an extremely interesting mill and the only one of its kind he ever heard of. There are five stands of two-high continuous rolls, all being alike, having a diameter of 23 $^5/_8$ in. and a length of 59 in. In front of this is a small set of three-high rolls, and to the right a larger set of three-high rolls. An 8-in. slab is delivered to the large three-high mill and broken down to 3 or 4 in. thick. This slab is then cut in half and put into a reheating furnace. One of the halves then goes to the small three-high mill and is reduced to $^9/_{32}$ in. (7 mm.) thick and then without reheating is put into the continuous stands. This thickness ($^9/_{32}$ in.) is always the same and the reduction is varied on the continuous mill to give the required final thickness.

The sheet is finished about 60 ft. long and is of course in all the stands at the same time. Sheets are always rolled singly and never in packs or doubled, and are from 40 to 50 in. wide. The stands are about 9 ft. from center to center and no idle rolls or automatic tables of any kind are used, simply stationary guides 6 or 8 in. high and a cast-iron plate between the stands on which the sheet slides. The gear train gives the first stand rolls 30 r.p.m., the next $37^1/_2$, then 45, $52^1/_2$, and finally 60 for the last stand. When the author saw the mill it was rolling a final product of 12 gage, making a total reduction in the five stands of some 58 per cent (from 7 mm. to 3 mm.).

Several points of great interest present themselves in connection with this mill. The first is the fact that such a thin piece of steel could be in all the five stands of rolls at the same time and not either tear or be crumpled between them. There is a great deal of confusion as to the pull exerted by rolls generally on steel, but as a matter of fact there is little if any pulling action, assuming of course the steel to be free and not held by any outside force. The resultant of the various forces acting on the steel must be vertical; for if it were inclined there would be an unbalanced horizontal component which would cause acceleration, making the bar go faster and faster. As such an action does not occur, this resultant force must be vertical. And therefore if the speeds and drafts are correct among the various stands of rolls, the sheet will not "pull" itself to pieces going into the rolls, assuming of course that the shape of the rolls is also right.

This continuous mill has demonstrated the fact that not only can the shape of the rolls be controlled but the speeds and drafts among the various stands can be properly adjusted, at least for single sheets as thin as 14 gage.

Another point of great interest is the fact that the back end of the sheet comes out thicker than the front end, due to the rapid loss of heat while in the continuous rolls. The finished sheets are respectively 2.5 mm. and 2 mm. thick at the edges at the back and front ends and 60 ft. long. To operate this mill economically it must work these long lengths and it is their practice to cut the 60-ft. sheets into short pieces, and afterward sort together the corresponding thicknesses from the different long lengths of finished sheets so that the variation of thickness will not be noticeable to customers.

The author was told that the mill was not a great financial success as there was not demand enough to keep running steadily on these particular gages. Further, the engine running the continuous mill was of about 1000 hp. normal rating and totally inadequate to run the mill satisfactorily.

Little experimenting had been done in trying to roll two sheets in a pack, for the furnace layout made it almost impossible to do so. However, the little that had been done seemed to show, as one would expect, that the thinner the sheet the greater the non-uniformity of thickness. It would seem that a reversing two-high mill, receiving alternately the hot and cold ends of the steel, might equalize this thickness and possibly be more satisfactory than the five continuous stands. So the question would naturally arise as to the best method to employ in rolling 12- and 14-gage sheets.

Then, too, it would be impossible to take this 12- or 14-gage material rolled on a special mill and finish it on the ordinary two-high sheet mill. Shapes of sheets and rolls will not fit, and while one of two packs might be rolled with care, the scrap loss would be enormous and this has been tried commercially and failed. It has also been suggested and thought possible to reduce the cost of sheet rolling by starting with the product from a universal plate mill instead of a sheet bar mill. If a universal plate of 7 or 8 gage and of accurate width were cut to proper size it would be equivalent to doing away with some of the present roughing-down process. However, when the price of universal plate is taken into account there is little or no gain; and in addition the difficulty of doing good work has been very greatly increased.

At first thought it would seem that sheets might be successfully rolled in packs on a two-high reversing mill. The condition of the same two rolls in the same relation to each other and the same pack of steel is what we have in the commercial mill now; and certainly with reversing roller tables, etc., a large saving in labor would result, even if the tonnage per set of rolls was not increased. However, it must be remembered that in a reversing mill first one end of the pack and then the other would be entered; and that this thin pack of sheets would have to be first drawn in one direction and then in the opposite direction; and that the two ends of a pack are not alike. So that we really have a very different condition from the ordinary two-high stand.

This sheet-machinery problem is a real problem, but as the author sees it, the only logical way of approach is from the scientific experimental side. It has been pretty well demonstrated that practice cannot furnish enough information. We need more knowledge of what actually occurs in rolling, what are the pressures, heat distribution, radiation, friction, etc., and when enough data and information are at hand, new ways and means, as always happens, will be indicated.

Relative Efficiency of Various Types of Condensing Apparatus

Results of Comparative Tests Carried Out on Double-Pipe Coils, Submerged Coils With and Without Manifolds, and Cooling Towers, and of Value as a Guide in the Selection And Design of the Most Efficient Type of Condenser

By ALLEN F. BREWER[1] and FRANK A. STIVERS,[2] PORT ARTHUR, TEX.

Among the many problems confronting engineers today there is none of more vital importance than that of improving the efficiency of condensing apparatus used in connection with the distillation of various liquids. However modern may be the process of distillation in practice, it will continue to fall short of its ultimate purpose—increased production—if the condensers in use are unable to stand forcing or are inadequate in their ability to perform the heat transfer and cooling required. The subject of heat transfer or conduction through metal with oil or oil vapor as one of the mediums has been mentioned by Dean P. F. Walker, of the University of Kansas in his paper, The Need of Research in the Industrial Field,[3] as a problem of frequent discussion among refining engineers; the latter without a doubt having had the condenser in mind throughout.

In order to arrive at conclusions concerning this problem which would ultimately be of value as a guide in the selection and design of the most efficient type of condenser, certain experiments have been carried out by the authors on a number of the most general designs of such apparatus for the purpose of obtaining data indicative of the relative efficiency of each. On account of the difficulties in construction that would have arisen, as well as the variation in operation, had any vapor other than steam been used as a medium to be condensed, it was considered best to carry out all tests with low-pressure steam. It is quite evident that the relative ability of each type of condenser as far as heat transfer is concerned is the same whatever the vapor passing through it; therefore the authors have felt justified in having conducted their experiments using the most uniform vapor available, i.e., steam.

Types of Apparatus Tested

Four types of apparatus were tested, namely:

Double-Pipe Coil
Submerged Coil, Not Manifolded
Submerged Coil, Manifolded
Cooling Tower.

Descriptions of these immediately follow.

Double-Pipe Coil. Built of 2-in. pipe within 3-in. pipe. Length of 3-in. pipe between fittings, 18 ft. 2 in.; effective length of 2-in. pipe, 19 ft. 2 in.; overall length of coil, 20 ft. 2 in.; height, 6 ft. 3 in.; area of cooling surface, 146 sq. ft. Coil supported vertically between two sets of 3-in. pipe driven into the ground with holes drilled at proper intervals to support bolts for the coil pipes. Solid-end fittings manufactured by the York Manufacturing Company for refrigeration purposes were used. Eleven sets of fittings in all with extra inlet and outlet fittings. Low-pressure steam used in all runs on this apparatus. Steam inlet at top of coil to pass between 2-in. and 3-in. pipes. Condensate outlet to bottom of coil and therefrom to tank and scale for weighing. Cooling-water inlet at bottom of coil within the 2-in. pipe. Outlet at top of coil, thence to ditch. All cooling water taken from hydrant line and metered.

Submerged Coil, Not Manifolded. Built of 30 lengths of 2-in. pipe, 8 ft. long, joined together with standard return bends. Arranged in a coil five pipes high and six pipes wide. Total area of cooling surface, approximately 162 sq. ft. No manifold fitted, therefore same steam particles entered at top and passed back and forth through all the pipes to leave the outlet at the bottom and flow to a tank and scale for weighing. Coil set in a steel tank 2 ft. 4 in. high, 3 ft. 9 in. wide and 10 ft. long. Seams of tank doped to prevent leakage. Cooling water taken from hydrant line via meter and 2-in. pipe to the bottom of the above-mentioned tank. Water overflow at top of tank via 3-in. pipe to ditch. As close to counterflow as possible in such an apparatus was thus obtained. Size of coil overall, 20 in. high by 24 in. wide

Submerged Coil, Manifold Type. Built of 30 lengths of 2-in. pipe, 8 ft. long, manifolded at inlet and outlet into five sections of six pipes each. Intermediate connections of all piping was made with standard return bends. Total area of cooling surface was approximately 162 sq. ft. Live steam used due to lack of available exhaust steam. Steam inlet at top of coil via manifold. Controlled by a valve and gaged. Condensate outlet via bottom manifold and thence to a tank and scale for weighing. Coil set in a steel tank 3 ft. 2 in. high, 2 ft. 1 in. wide and 10 ft. long. Seams calked with asbestos packing to prevent leakage Cooling water taken via hydrant line and meter and 2-in. pipe to the bottom of the tank. Water overflow at top of tank via 3-in. pipe to ditch. As close to counterflow as possible in such as apparatus was thus obtained. Overall size of coil, 23 by 23 in.

Cooling Tower. Built of 2-in. malleable iron pipe and standard fittings, three pipes wide, nine pipes high (i.e., three nine-pipe sections) with manifolded inlet and outlet. Overall lengths of pipes, 8 ft.[1] Distance center to center horizontally 19 in., vertically, 8 in. Approximate area of cooling surface, 146 sq. ft. (including horizontal pipes, vertical nipples, standard fittings and manifold fittings, etc.) Overall height of coil, 5 ft. 3 in., length 8 ft. 5 in., width 3 ft. 9 in.

Cooling-water distribution over the tops of the coils was carried out by means of a 2-in. inlet pipe, taking water from hydrant line via a meter and thence to a tin distributor box at the opposite end of the coil from where the steam entered. Flow of both steam and cooling water was parallel; i.e.. from top to bottom. From the distributor box the cooling water was fed to the top pipes of the coil by means of wooden troughs, having a canvas strip in the apex of each. These troughs were easy to adjust to obtain equal and uniform flow over the coil, the water flowing over the top of each trough and dripping down the canvas strip on the top pipe and thence in sequence to the lower runs of pipe. It was attempted to obtain a certain amount of counterflow by installing a series of six garden-hose nozzles attached vertically to $^3/_4$-in. piping fed by the main cooling-water supply and controlled by a valve. This proved, however, to have no material advantage and to be beyond proper control.

Wood baffling 4 in. on centers constructed to uprights at each corner of the coil was installed around the entire apparatus to do away with splash and still provide free access for the air. Exhaust steam of 5 in. pressure was used, being led to the coil via a top manifold and controlled by a valve. Condensate outlet was via a bottom manifold and thence to a barrel and scale for weighing. Steam was trapped and pipes covered to obtain as dry steam as possible. All cooling water used was taken from the hydrant and metered.

Method of Conducting Tests

Inasmuch as the ultimate purpose in view throughout the experiments in question was to obtain a knowledge applicable to the design of practical condensing apparatus of maximum efficiency for condensing oil, vapor and cooling the resultant condensate to final temperatures in the neighborhood of 100 deg. fahr., all data were taken with this point constantly in mind. Low-pressure steam of an average quality of 98 per cent was used throughout as the condensing medium. In every case four variable factors presented themselves for consideration, namely:

Temperature of cooling water entering condenser
Quantity of cooling water
Temperature of condensate
Quantity of condensate.

There was as well a certain variation occurring in the heat content and temperature of the steam, but not of sufficient amount to materially influence the results obtained. Throughout the experiments the temperature of the inlet cooling water was held as constant as possible, thus eliminating this variable from further consideration. Three separate series of tests were therefore carried out on each type of condenser, maintaining one of the three remaining variable constants in each case, namely:

1 Volume of condensate constant; temperature of condensate and volume of cooling water varied

---

[3] Mechanical Engineering, September 1920, p. 487.

Presented at a meeting of the Houston Section of The American Society of Mechanical Engineers, Houston, Tex., March 25, 1921. Slightly abridged.

[1] See Bureau of Mines Bulletin No. 176, page 36: "It is well when possible to place pipes in a continuous coil so that an air space not less than twice the diameter of the pipe will be left vertically between pipes of the same coil, and a space 8 to 10 times the diameter of the pipe will be left open horizontally between sets of coils."

2 Temperature of condensate constant; volume of cooling water and volume of steam varied

3 Volume of cooling water constant; temperature of condensate and volume of condensate varied.

Results Obtained in the Tests

The results of the tests are given in Table. In every series the order of efficiency was practically the same, namely:

1 Double-Pipe Coil
2 Submerged Coil, Not Manifolded
3 Submerged Coil, Manifolded
4 Cooling Tower.

The results cannot be assumed as indicative of the capacity of various condensers under practical conditions, inasmuch as in some cases it required as high as 40 lb. pressure to force the steam through the coils. The data are intended purely to show a comparison of efficiency and relative heat transfer.

A comparison of the manifolded and non-manifolded submerged coils indicates the same limitations. In fact, even through the efficiency of a non-manifolded coil is the higher, yet it may be necessary in practical operation to manifold the coil in order to provide adequate area for flow; although this must be done at the expense of a decrease in heat transfer.

The double-pipe coil gives the nearest perfect counterflow of the mediums as is indicated by the high outlet-water temperature and low condensate temperature. In the submerged coil perfect counterflow cannot be gained, but a partial effect is obtained by putting the inlet water entrance at the bottom and at the opposite end of the coil from the steam inlet which is located at the top of the coil. The data show a cooler outlet water and warmer condensate than for the double-pipe coil. The handicapping feature of the cooling tower is that an unavoidable parallel flow of the mediums exists; and a high outlet temperature of condensate prevails.

The possibility of spraying the outside of the double-pipe coil is worthy of mention and consideration in the construction of a practical condenser. No actual data were taken to support this contention in the experiments in question, but it was noticed that a marked heat transfer by evaporation was clearly evident on several occasions when the apparatus was operating and showers occurred.

There is one advantage held by the cooling water which must not be overlooked, namely, the fact that evaporation is used for carrying away the major part of the heat, only a small amount being transferred as sensible heat to the cooling water. This is a practical advantage if the cooling water is to be spray-cooled and reused. The effect that weather conditions have on the coils is marked. When humidity is high, when there is rain or little breeze, evaporation will be decreased and vapor clouds hang heavily around the coils. Most efficient operation was found to occur when a light breeze prevailed and the air was dry.

TABLE 1 DATA OBTAINED IN TESTS OF VARIOUS TYPES OF CONDENSERS

Length of test, min.	Temp. of inlet water, deg. fahr.	Temp. of outlet water, deg. fahr.	Steam pressure, lb. per sq. in.	Temp. of steam, deg. fahr.	Temp. of condensate, deg. fahr.	Cooling water per min. gal.	Condensate per min. lb.

In conclusion, the following points may be emphasized as being brought out by the data obtained in the tests:

1 On a basis of heat transfer the double-pipe coil is far superior to any of the other types of condensers tested; the degree of superiority and the comparative efficiencies of the others being shown clearly by the resultant curves.

2 Considering the submerged coils, the non-manifolded type of apparatus shows a better heat transfer than the manifolded coil under like operating conditions.

3 On a basis of low outlet temperature of the cooling water, the cooling tower is much superior to other coils, as the data indicate. This characteristic is of value if the cooling water is to be cooled and reused.

DESIGN OF STEAM POWER STATIONS FOR HYDRAULIC RELAY

(*Continued from page 652*)

Miscellaneous power service and lighting should, in general, be completely relayed against more than momentary interruption; for some classes of power, frequently that applied to electrolytic processes, for example, longer interruption of service is not of so serious moment, not sufficiently serious to warrant the expense of full relay; on the other hand, an extensive d.c. network, such as that in large metropolitan cities, must be absolutely safeguarded against interruption, however brief.

When the steam relay station is to serve as an instantaneously available reserve, the necessary excess capacity in generating units must be maintained on the line and actually under steam at all times. Station design to provide most economically for such service must afford, for minimum investment, a maximum of flexibility in capacity with minimum stand-by charges. Characteristics in equipment peculiarly favoring these requirements are:

1 Combination electric-steam drive on the larger auxiliaries, such as circulating pumps and mechanical-draft fans, for the units operated as floating stand-by
2 Turbo-generating units with direct-driven exciter, and with overspeed-controlled steam bypass for turbine-blade cooling independent of normal governing valves
3 High ratio of turbo-generator capacity in comparison with point of lowest water rate
4 Wide flexibility with quick response in control of boiler output and rate of combustion
5 High ratio in capacity of combustion equipment vs. area of boiler heating surface.

Where commercially available, fuel oil with mechanical atomization is particularly advantageous on this class of service, and its use permits the fulfilment of these boiler-plant requirements to an almost ideal degree. With proper design the response to control is practically instantaneous; capacity attainable is the highest of any commercial fuel. Oil fuel has the added advantage, particularly important in stand-by service, of minimum banking loss.

Pulverized coal, bituminous or sub-bituminous, for the larger plants, is only second to oil in flexibility of control and low banking loss. In general the underfeed type of mechanical stoker, given proper ratio of grate area to heating surface, will also fully meet the requirements in both flexibility and capacity, but banking losses are necessarily higher than for either oil or pulverized coal.

The class of fuel to be adopted in any particular case should be governed by the local conditions of fuel market, load and relay-station load factor, present and prospective, station location and capacity. However, it is usually true that fitness of equipment, and of its arrangement, for the requirements of the fuel determined upon, are more important than selection of type of fuel.

Emergency relay service on loads for which absolute continuity is of less vital importance will normally involve actual readiness to serve only during periods of anticipated power deficiency such as between seasons when stream flow is precariously near the actual load requirements and any slight diminution of flow will necessitate calling upon the relay station, or when there is possibility of sudden ice accumulation, or threatening floods.

For relay service of this character it will usually be sufficient to maintain a few boilers under fire and the larger of the essential auxiliaries turning over. The general characteristics of equipment outlined for conditions requiring instantaneous availability of the reserve apparatus will be advantageous in this case also. The combination electric-steam drive for auxiliaries may be omitted in the interest of first cost as the relay is not necessarily intended to meet full failure of hydraulic power, but the provision of electric drives for one complete set of essential auxiliaries, as recommended for the normal deficiency make-up of relay station to permit prompt starting of such equipment without waiting for steam, will usually be found particularly advantageous under the service conditions now considered. It may also under some conditions be advantageous to make use of electrical heaters in maintaining hot-water circulation in certain of the boilers, instead of actually holding them under fire. Oil is again the ideal fuel, but it is questionable if in the average case pulverized fuel will possess any advantage over the forced-draft underfeed stoker. New developments may, of course, readily change the relative status of these two methods of burning coal. In general the features of design which are specially advantageous for this type of relay are common to the instantaneous type of relay and are readily embodied in the station designed for the simpler type of make-up service.

Considering again the general characteristics and requirements of the steam relay station, the feature which should be regarded as secondary only to low construction cost and adequate dependability is that of low attendance requirements, and not merely for the non-operating period but for actual operation as well. With this object in view the design should tend to large units and, as far as compatible with thorough simplicity, to automatic control. Where feasible, combining the functions of distributing station with those of the hydraulic relay; assists materially in holding down both construction costs and attendance for the relay station. It should be borne in mind, however, that maximum returns on the investment in any type of steam power station can only be had through skilled and well-trained operators. Such men cannot be picked up on a moment's notice. It is true that it is often possible during periods of plentiful water supply to distribute men from the steam stations through other departments, but the number of men that may actually be employed in this way is limited. Where men are held over long periods without really effective employment, there is invariably loss of efficiency and of morale.

DESIGN AND CONSTRUCTION OF 16-IN. DISAPPEARING CARRIAGE

(*Continued from page 660*)

machined to varying diameters so as to give a uniform pressure throughout the stroke. By means of these various hydraulic systems, the enormous weights move from one position to another without the least shock or perceptible vibration.

How closely the pressure in the recoil cylinders can be kept constant, the assumption made in the calculation, is illustrated by indicator-card records taken from the 16-in. disappearing carriage, model of 1912 (Fig. 5). The first diagram shows the operation of the recoil system during recoil. For the first five inches of recoil there is no pressure on account of the void left in the cylinder to take care of the expansion of the oil. The pressure quickly builds up to a maximum of about 1200 lb. per sq. in. and remains constant over the remainder of the length of recoil. The velocity curve shows that the maximum velocity of the top carriage of about 10 ft. per sec. is quickly reached and that this velocity is reduced almost on a straight line over the length of recoil. The time curve shows that the gun moved from the in-battery to the recoiled position in about two seconds. The velocity and time curves were obtained by means of velocimeters.

The second diagram shows the operation of the same system as the gun goes from the loading or recoiled position to the in-battery or firing position. There is no appreciable pressure in the recoil cylinder until the buffer mechanism, previously described, comes into play. This buffer acts for the last 16 in. of counter recoil. The pressure quickly builds up to about 3500 lb. per sq. in. and the velocity which has reached over 3.5 ft. per sec. is quickly reduced to zero. The time for the gun to move into battery is shown to be about seven seconds.

The third diagram shows the pressure in the hurter cylinders at the end of recoil. The orifices are proportional so that the pressures will remain nearly constant throughout the stroke.

The construction of the elevating arm may be of interest because by making this arm elastic the force which it must carry is reduced from about 4,000,000 lb. to less than 1,000,000 lb. When a suddenly applied load is brought upon this gun, the oil in the cylinder of its recoil mechanism is throttled past the piston head through two grooves of varying cross-section cut in the cylinder wall parallel to the longitudinal axis. The cross-sectional area of these grooves is such that a constant pressure is maintained in the cylinder throughout the stroke. The piston remains stationary while the cylinder moves. As soon as this heavy load is relieved, the springs force the arm to return to its original length, and the recoil mechanism again acts to prevent the sudden action of the springs.

The Various Determinations of the Specific Heat of Steam and Their Technical Significance

By H. SCHMOLKE

IN THE past few years several attempts have been made to determine the specific heat c_p of superheated steam at constant pressure for a wide range of temperatures and pressures. This is of great practical importance since c_p is one of the most valuable physical magnitudes, and in so far as its relation to pressure and temperature is known, it makes possible the determination of all the other thermodynamic properties of steam, as has been shown by Planck. Thus, if u denotes the internal energy of steam, v its specific volume, p its specific pressure and A the heat equivalent, then the heat content of steam is found to be $i = u + Apv$, this being obtained by means of the equation—

$$c_p = \left(\frac{\partial i}{\partial T}\right)_p$$

in which T denotes temperature, and i can be determined provided c_p has been found by measurement. Further, the entropy s can be determined from the equation—

$$c_p = T\left(\frac{\partial s}{\partial T}\right)_p$$

if the specific heat of the steam is known for all values of p and T. This makes it possible to determine from experimental data the function—

$$\varphi = s - \frac{i}{T}$$

and from this can be determined all the magnitudes defining the state of steam, since if the above value for i is introduced into the function for φ, the following equation is obtained:

$$d\varphi = ds - \frac{du + Apdv + Avdp}{T} + \frac{u + Apv}{T^2}\,dT \;\ldots\ldots [1]$$

Also since

$$ds = \frac{du + Apdv}{T}$$

another expression for the same function is obtained, namely:

$$d\varphi = -A\,\frac{v}{T}\,dp + \frac{u + Apv}{T^2}\,dT \;\ldots\ldots [2]$$

but in accordance with general rules of mathematics the total differential must be—

$$d\varphi = \left(\frac{\partial\varphi}{\partial p}\right)_T dp + \left(\frac{\partial\varphi}{\partial T}\right)_p dT \;\ldots\ldots [3]$$

and likewise

$$\left(\frac{\partial\varphi}{\partial p}\right)_T = -A\,\frac{v}{T}, \text{ and } \left(\frac{\partial\varphi}{\partial T}\right)_p = \frac{u + Apv}{T^2} = \frac{i}{T^2} \;\ldots [4]$$

From this it follows that

$$Av = -T\left(\frac{\partial\varphi}{\partial p}\right)_T;\; i = T^2\left(\frac{\partial\varphi}{\partial T}\right)_p;\; s = \varphi + T\left(\frac{\partial\varphi}{\partial T}\right)_p \;\ldots [5]$$

and

$$u = T\left[T\left(\frac{\partial\varphi}{\partial T}\right)_p + p\left(\frac{\partial\varphi}{\partial p}\right)_T\right] \;\ldots\ldots [6]$$

By partial differentiation of φ with respect to either p or T all the fundamental magnitudes of steam can be found, and because of this φ is called the characteristic function of steam.

This is of importance not only for the superheat range of steam, but has a certain significance for the range of saturation, as it may be shown that at the limit of saturation the characteristic function has the same value for both steam and water. If superheated steam and water are brought into contact under conditions where all outside influences are excluded, then at each change of state the volume V, the internal energy U, and the mass M of the entire system must remain constant, and hence $\delta M = 0$, $\delta V = 0$, and $\delta U = 0$. The notation δ indicates a virtual, infinitely small variation of state, while d corresponds to an actual process. Since $M = M_1 + M_2$ (where subscript 1 refers to steam and subscript 2 to water), and similarly one may write $V = M_1v_1 + M_2v_2$ and $U = M_1u_1 + M_2u_2$, it is advisable to express the above equations of condition in the form—

$$\Sigma\delta M_n = 0,\; \Sigma M_n\delta v_n + \Sigma v_n\delta M_n = 0, \text{ and } \Sigma M_n\delta u_n + \Sigma u_n\delta M_n = 0 \;\ldots [7]$$

Here Σ denotes the summation of the magnitudes indicated by subscript 1 and subscript 2. If, in the system under consideration, equilibrium prevails, the entropy is a maximum and therefore its variable $\delta S = \Sigma M_n\delta s_n + \Sigma s_n\delta M_n$ is zero. Since, further, as has been shown above, one may write—

$$\delta s = \frac{\delta u + Apdv}{T}$$

it follows that

$$\delta S = \Sigma\,\frac{M_n\delta u_n}{T_n} + A\Sigma\,\frac{M_np_n\delta v_n}{T_n} + \Sigma s_n\delta M_n = 0 \;\ldots\ldots [8]$$

From the three equations of condition of state, expressions may be found for δM_2, δv_2 and δu_2. These expressions are introduced into Equation [8] for δS, which gives

$$\delta S = \left(\frac{1}{T_1} - \frac{1}{T_2}\right)M_1\delta u_1 + A\left(\frac{p_1}{T_1} - \frac{p_2}{T_2}\right)M_1\delta v_1 + \left(s_1 - s_2 - \frac{u_1 - u_2}{T_2} - \frac{Ap_2(v_1 - v_2)}{T_2}\right)\delta M_1 = 0 \;\ldots\ldots [9]$$

The three variables δu_1, δv_1 and δM_1 appearing here are entirely independent of each other and therefore in order that δS shall become zero for all changes of state, it becomes necessary that each of the three coefficients become zero; for this to take place it is necessary that $T_1 = T_2 = T$, and $p_1 = p_2 = p$, and—

$$s_1 - s_2 = \frac{u_1 - u_2 + Ap(v_1 - v_2)}{T}, \text{ or } s_1 - \frac{u_1 + Ap_1v_1}{T_1} = s_2 - \frac{u_2 + Ap_2v_2}{T_2} \;\ldots\ldots [10]$$

This proves that in the state of equilibrium the characteristic functions of steam and water are equal to each other. But the former, as has been shown above, may be expressed as a function of p and T providing c_p has been determined by measurement.

For example, Dieterici found that the specific heat of water is $c_{fl} = a - bT + cT^2$, where a, b and c are constants. From this it would appear that the entropy of the liquid is

$$s' = \int \frac{c_{fl}\,dT}{T}$$

and its heat content at the limit of saturation is

$$i' = \int c_{fl}\,dT + Apv_0.$$

Since v_0, the specific volume of water at 0 deg, cent., is known, the characteristic function $\varphi' = s' - i'$ may be computed and set down as being equal to the corresponding characteristic function of pure steam. This in its turn makes it possible to determine the saturation pressure and the heat of evaporation, provided, however, the specific heat of the steam has been correctly determined by measurement, which once more proves the great thermodynamic value of a correct knowledge of the specific heats of steam.

Prior to 1906 only very meager information was available as to the numerical relation between the specific heat of steam and pressure and temperature variations. Regnault was one of the first investigators to take the trouble to determine experimentally the specific heat of steam at atmospheric pressure and a temperature of about 175 deg. cent. (347 deg. fahr.), and he found that at these conditions $c_p = 0.48$. For a while this value was accepted not only as the average value within the temperature range of 128 to 221 deg. cent. (262.4 to 429.8 deg. fahr.), but a further step was taken and an erroneous conclusion drawn from Regnault's observations to the effect that c_p is generally independent of T.

R. Mollier accepted this assumption as a basis in working out his J-S diagram for steam, first published in 1904, and which had since become of great practical importance. He did this notwithstanding the fact that experiments carried out considerably earlier than the publication of his papers by Mallard and LeChatelier have given sufficient information to indicate the incorrectness of the above assumption. Although these two investigators clearly established that the numerical value of c_p increases in the higher ranges of temperature, nevertheless the belief in the invariability of the specific heat of steam continued to prevail and variations were admitted only within the highest ranges of temperature. As to the dependence of c_p on pressure, no information whatsoever appears to have been available at that time (1904). An important step in advance was made with the publication of the investigations of R. Linde and H. Lorenz in 1905. The former numerically calculated the specific heat c_p from the experimentally determined value of specific volume v and found that this decreased with increase of temperature and increased with increase of pressure. Lorenz came to the same conclusion from an investigation of specific heat by direct measurement, and at about the same time Callendar arrived at similar conclusions which compelled Mollier to revise his recently published diagram.

While the above investigations brought about a change of view as to the functional relation, if any, between the specific heat of steam on one hand, and temperature and pressure on the other, they did not solve the problem of the quantitative character of this relationship, and it was the work carried out at the Laboratory of Engineering Physics in the Munich High School by O. Knoblauch and M. Jakob that gave the first reliable figures (1906).

In the original experimental installation as used in Munich, the steam from the boiler went first into a water separator where dewatering was accomplished by mechanical means and thence passed into an electric superheater, in which latter the steam, after thorough drying, was raised to a temperature of t_1 deg. cent. Then in a second superheater the temperature was raised to t_2 deg. cent. by supplying the steam with a precisely measured amount of electrical heat energy equal to W cal. per hr. Thereupon the steam was condensed in two condensers and its weight G kg. per hr. was determined.

In order to compute the average specific heat within the temperature range of t_1 to t_2 from the data of measurement, employment was made of the formula—

$$c_p = \frac{W - V}{G\,(t_2 - t_1)}$$

where V is the unavoidable heat loss determined by separate tests.

The experiments were carried out over a pressure range of 2 to 8 atmos. and with temperatures ranging from around saturation to 350 deg. cent. (662 deg. fahr.). On the whole they led to the following conclusions: c_p, with temperature T constant, increases within increase of pressure, especially in the region near saturation; with the pressure constant c_p decreases with increase of temperature, reaches a certain minimum value, and then with increase of superheat begins to increase. The specific heat at 0 atmos. pressure is not constant, but rises with increase of temperature.

It would appear from this that the general conclusions arrived at at Munich, notwithstanding the presence of quantitative differences, are in the main in accord with former observations. These observations were further extended by the publication in 1911 of the investigations by Knoblauch and Hilde Mollier bearing on the specific heat of steam at pressures from 2 to 8 atmos. and temperatures of 350 to 550 deg. cent. (662 to 1022 deg. fahr.).

In these tests, also carried out in Munich, the boiler steam was dried in a gas-heated preheater and after it attained a temperature of t_1 deg. it was led into an electric superheater which constituted the real experimental unit. Here its temperature was raised to t_2 deg. cent. by the addition of an amount of heat energy W, and the steam was then condensed in a condenser. After weighing the condensate and determining the heat losses by a separate test, it became possible to compute the specific heat by the formula above referred to. The new tests have confirmed the increase in c_p with increasing pressure, likewise its initial falling off with rising temperature and the existence of a minimum. It was also found that within the limits of temperature of 350 to 550 deg. cent. (662 to 1022 deg. fahr.) the increase in specific heat with increase in pressure became constantly smaller, so that ultimately the difference of values of c_p at equal temperatures and various pressures could barely be determined. The increase in specific heat with increase in superheat was observable also in the above range.

The minimum value attained by c_p with increase in temperature and determined by the Munich experimenters was confirmed later by the important investigations of L. Holborn and F. Henning, who worked with atmospheric pressure and temperatures up to 1350 deg. cent. (2462 deg. fahr.).

Investigations at such high temperatures appear, however, to have a theoretical rather than a practical interest. Of greater engineering importance are the determinations published in 1917 from work carried on again in Munich by O. Knoblauch and A. Winkhaus concerning the specific heat at pressures of from 8 to 20 atmos. and temperatures from the limit of saturation to 380 deg. cent. (716 deg. fahr.). In these tests the experimental installation already described was used, and c_p was computed in the same manner as before. It was found that there is also an increase of specific heat with increase in pressure in the new range of high pressures. As compared with the data of tests made in 1911 there were found slight variations in the region near saturation. There the numerical values of c_p were shown by the new investigation to be somewhat lower than the previous investigation would indicate, the new values being closer in accordance with the values of Holborn and Henning. Although the tests at Munich were carried on to pressures up to 30 atmos., it may be said that dating from the appearance of the investigation by Knoblauch and Winkhaus c_p may be considered as definitely known within the ranges used in ordinary engineering. It is also claimed that the theory for making use of the experimental observations has also been carried to a full practical conclusion, and that such a conclusion was reached when it became possible to derive by calculation all the magnitudes of the state of steam from data obtained by measurement.

At the same time, however, the analytical work of deriving one of the magnitudes defining the state of steam from another is by no means easy. This was found when an attempt was made to derive the specific heat c_p from an equation found experimentally by R. Linde for the specific volume of steam, namely,

$$v = \frac{RT}{p} - (1 + ap) \times \left[C\left(\frac{373}{T}\right)^3 - D \right] \ldots\ldots [11]$$

in which R is the gas constant (47.1), and a, C and D are constants. Notwithstanding the fact that the above equation expressed with the greatest possible precision experimentally observed data, and the further fact that there is available for determining c_p from v the relation—

$$\left(\frac{\partial c_p}{\partial p}\right)_T = -AT\left(\frac{\partial^2 v}{\partial T^2}\right)_p \ldots\ldots\ldots\ldots\ldots [12]$$

derived by Clausius, the computation led to results which quantitatively could not be brought into accord with data found by actual measurement. The same happens when use is made of

the modified equation for specific volume proposed by Callendar, or the modification of the Linde formula given by Goodenough.

The reason for this was indicated in 1912 by Jakob. From the Clausius equation it follows directly that—

$$c_p = c_p{}^0 - AT \int_0^p \left(\frac{\partial^2 v}{\partial T^2}\right)_p dp \qquad [13]$$

when $c_p{}^0$ is the value of specific heat in the ideal gaseous state. Because of this, in order to obtain c_p from v, it becomes necessary to carry through a double differentiation of the equation for the specific volume. This latter, written in a simplified manner, has the form

$$v = \frac{RT}{p} - \Delta v$$

where Δv is a correction term expressing a deviation from the law of gases. Hence

$$\left(\frac{\partial^2 v}{\partial T^2}\right)_p = -\left(\frac{\partial^2 \Delta v}{\partial T^2}\right)_p \text{ or } c_p = c_p{}^0 + AT \int_0^p \left(\frac{\partial^2 \Delta v}{\partial T^2}\right)_p dp \qquad [14]$$

From this it would appear that the determination of c_p depends primarily on the uncertain correction term in the equation of state and the double differentiation of the latter may easily lead to error. It is easy to understand why the failure of previous attempts created an impression that it would be generally impossible to establish a satisfactory connection between v and c_p on the basis of the Clausius equation. Jakob disproved this view by deriving from specific heats specific volumes by means of a system of c_p isobars in the c_p-t diagram. He did this graphically by using the relation—

$$v = \frac{RT}{p} - \frac{1}{A}\int_{T_0}^T \int_{T_0}^T \frac{1}{T}\left(\frac{\partial c_p}{\partial p}\right)_T dT^2 \qquad [15]$$

which is derived from the Clausius equation and in which T_0 is the temperature of the ideal state of gas.

Jakob, however, also considered as hopeless all exclusively analytical attempts at solving this problem, and it was only in 1916 that R. Planck succeeded in deriving an expression for the shape of the c_p isobars, which, on one hand reproduces with sufficient precision the experimental data, and on the other hand, permits that double integration which is necessary in order to determine v from c_p, as would appear from the above equation. In this he was successful, which means that the values of specific volume analytically found by him were in sufficient accord with the volumes determined by actual measurement. Unfortunately, however, his work is of greater value from the point of view of mathematics than of practical engineering, because his equation of state is of such a complicated form as to make its use in engineering impossible. Complete success in this field was attained only in 1920 by G. Eichelberg, who gave to the c_p isobars an expression of very high precision:

$$c_p = c_p{}^0 + \frac{C_1 p}{T^4} + \frac{C_2(p + 2 \times 10^4)^{3.2} - C_3}{T^{15}} \qquad [16]$$

where C_1, C_2 and C_3 are constants. From this it follows that—

$$\left(\frac{\partial c_p}{\partial p}\right)_T = \frac{C_1}{T^4} + \frac{3.2C_2(p + 2 \times 10^4)^{2.2}}{T^{16}} \qquad [17]$$

If this is inserted in the Clausius equation we obtain—

$$A\left(\frac{\partial^2 v}{\partial T^2}\right)_p = -\frac{C_1}{T^5} - \frac{3.2C_2 \times (p + 2 \times 10^4)^{2.2}}{T^{16}} \qquad [18]$$

and by double integration with respect to T we have—

$$Av = \psi(p) + T\varphi(p) - \frac{C_1}{3 \times 4\, T^3} - \frac{3.2C_2(p + 2 \times 10^4)^{2.2}}{14 \times 15 \times T^{14}} \qquad [19]$$

The undetermined functions $\psi(p)$ and $\varphi(p)$ necessary for the solution of the partial differential equation can be taken care of by the assumption that when temperature T rises, the values of specific volumes approach asymptotically those of the ideal gas. If this be so, then

$$T = \infty,\ v = \frac{RT}{p}, \text{ and } \left(\frac{\partial v}{\partial T}\right)_p = \frac{R}{p}.$$

Hence $\partial(\varphi) = \dfrac{AR}{p}$ and $\psi(p) = 0$.

By inserting these values in Equation [19], an equation of state is found giving values of specific volumes in every respect in accord with those derived experimentally. The correction member of this equation has the form $f(p, T,)$ while that of the equations of Linde, Callendar and Goodenough has the form $f(p)g(T)$, and it is this latter form that has been cited by Jakob as the main reason for previous failures to derive analytically c_p from v. Jakob's objections do not hold against Eichelberg's formula and its comparatively simple structure appears to make it suitable for practical purposes. Thus by this means one can compute without much trouble the entropy s and the heat content i from the generally known thermodynamic equations—

$$di = c_p dT - A\left[T\left(\frac{\partial v}{\partial T}\right)_p - v\right]dp \qquad [20]$$

and

$$ds = \frac{c_p}{T}dT - A\left(\frac{\partial v}{\partial p}\right)_T dp \qquad [21]$$

Then again with expressions for i and s available, the preparation of entropy tables becomes very much simplified through the elimination of the time-consuming planimetering of c_p- and c_p/T-curves. Furthermore, the Eichelberg equation makes it possible to determine analytically the exponents of the adiabatics of superheated steam, so that on the whole this equation may be considered as the keystone of a notable series of important investigations in a field of scientific and engineering importance. Improved Methods of Fatigue Testing

By H. J. GOUGH

REPORT submitted in April of this year by the author, member of the Engineering Department of the National Physical Laboratory, to the Materials and Chemistry Committee of the Aeronautical Research Committee, and published in advance of its official appearance.

The machine used in these tests is shown in Fig. 1 with some slight changes dealing chiefly with the lubrication arrangements and method of drive.

SccS is the central crankshaft with a heavy flywheel *F*. It is driven by a direct-coupled electric motor—not shown. The throw, or double radius, of each crank is 1 in. Two connecting rods *KK* join the rotating cranks *cc* to the balanced rocking arms *CC*, whose radii are 4 in. The shafts of the rocking arms end in clutches *QQ*, and the spindles of the two oscillating masses *WW* have similar clutches into which the ends of the test pieces *TT* can be secured. The oscillating masses *WW* are built up of a number of circular disks, the polar moments of inertia of which are known.

The original article shows the method of calculating stresses in specimens under test and the forms of test pieces—hollow and solid. It is obvious from the description of the machine that the fatigue on the material was induce by the action of the unbalanced flywheels.

Several methods of determining the torsional fatigue limit were considered, namely: (1) The rate of increase of strain with stress; (2) the rate of increase of width of the hysteresis loop with stress; and (3) the rate of increase of temperature due to internal work with stress. Methods 1 and 3 were those chiefly used. The specimen was placed in the holders and the machine run at low speed. The speed of the machine was hand-controlled throughout the test. When the galvanometer reading had become steady, it and the

strain-scale reading were taken. The speed was then increased by increments of 10 r.p.m., both scales being read at each speed. At a certain speed dependent upon the material, the amplitude of the motion of the spot suddenly increased. In most cases this increase was quite sudden and definite, the band of light opening out at both ends. In some cases the galvanometer mirror also swung across at the same time. Sometimes, however, this effect happened at a slightly higher speed and the yield point was seldom shown as clearly by the thermocouple as by the strain scale.

The material chiefly experimented on was 0.65 per cent carbon steel. The scale readings for both the thermocouple and strain

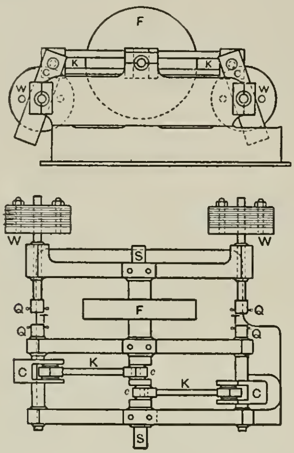

Fig. 1 Stromeyer's Machine for Measuring Alternating Torsion

scale are plotted against speed of machine in Figs. 2 and 3. The very definite nature of the yields is shown clearly by the curves. The "yield" point incurred at stresses of ±10.2 and ±10.5 tons per sq. in. for the solid and hollow test pieces, respectively. The difference may safely be ascribed to slight differences between the actual specimens tested. The thermocouple curve for the hollow specimen indicates the same "yield" point as the strain or deflection curve. With the solid specimen, however, the thermocouple curve gives the breakdown as occurring at a slightly higher speed than that given by the deflection curve. This difference is highly important as affecting the calculated stress at which breakdown occurs.

Reference to the formula from which the stress is calculated—

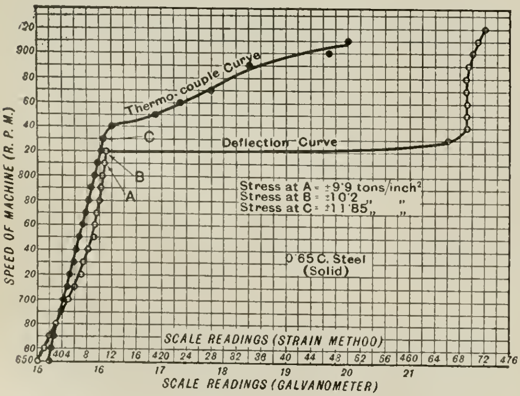
$$f_s = \pm KM\theta n^2/I$$

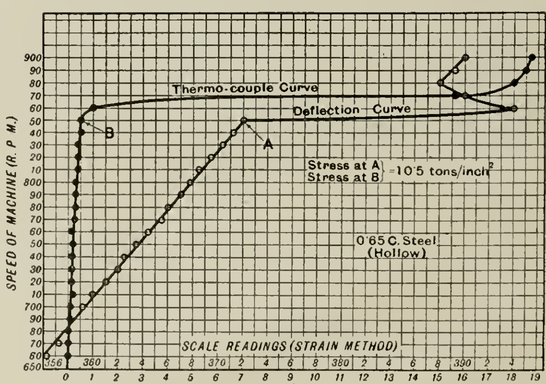
shows that the stress is proportional to the amplitude of the oscillating mass. In Fig. 2 the calculated stresses at the points A, B and C are as follows: Stress at A = ±9.9 tons per sq. in.; stress at B = ±10.2 tons per sq. in.; stress at C = ± 11.85 tons per sq. in.

Considerable error is involved if the yield point is assumed to be (from the thermocouple curve) at C instead of at B (from the strain curve). In several other tests a similar "lag" was noted on the thermocouple curve.

To show this point more clearly, Figs. 2 and 3 have been replotted to "stress" ordinates—see Figs. 4 and 5. That the fatigue limit is masked by the thermocouple in the case of the solid specimen may have been due to the following causes: (1) The galvanometer used may not have been sufficiently sensitive; (2) owing to the larger heat capacity of the solid specimen, the lag of the thermocouple may be a time effect. In some further experiments now being carried out, a galvanometer of much greater sensitiveness is being employed. Also a longer time interval is allowed before the galvanometer is read. With these precautions the thermocouple indicates the fatigue range at a stress in agreement with that given by the yield method. The change of slope of the stress-temperature curve is, however, nearly always less than that of the stress-strain curve. This fact would lead to the inference that if the calorimetric method of determining fatigue limits were used in a machine in which the stress applied was independent of the strain—the usual type of testing machine—it would be extremely difficult to estimate the stress at which the slope of the stress-temperature curve changed.

There is no doubt that the success of the yield and calorimetric methods described in this paper are due to the state of instability of the specimen under test, owing to the character of the machine employed. Directly a yield in the specimen occurs, the stress is automatically increased, producing a greater yield, and this multiplying effect continues until a second state of equilibrium of partial stability occurs. Careful deflection readings must obviously be taken in order to calculate the fatigue limit as shown by the thermocouple curve. Three observers are necessary for a calorimetric determination, whereas only two are required for the strain method. These facts lead to the conclusion that the strain method is more accurate and practical, although the calorimetric method is useful as a check.





Figs. 2 and 3 Thermocouple and Deflection Curves for Solid and Hollow Specimens of 0.65 per cent Carbon Steel

From these tests on 0.65 per cent carbon steel, the following conclusions were drawn: (1) That the fatigue limit under reversed shear stresses is marked by a "breakdown" or "yield" point in the material, as in Smith's experiments with direct stresses; (2) that this breakdown point is independent of the form of the section, solid or hollow; (3) that Guest's law applies to fatigue stresses. It can then be seen that these results and conclusions confirm those obtained by Dr. J. H. Smith for alternating direct stresses.

A curious phenomena was observed in the case of nickel, Fig. 6.

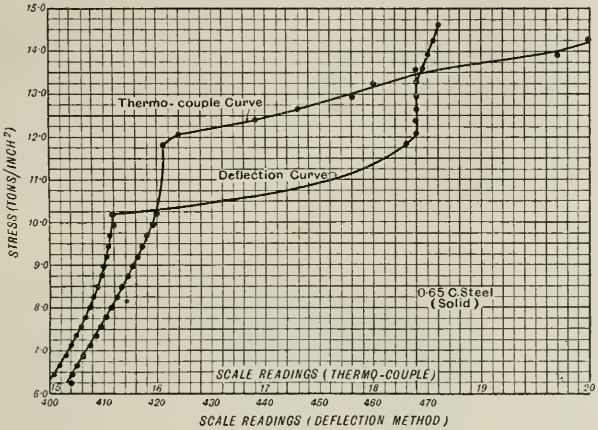
The material definitely yielded and again recovered. This is the only material which has, so far, behaved in this way.

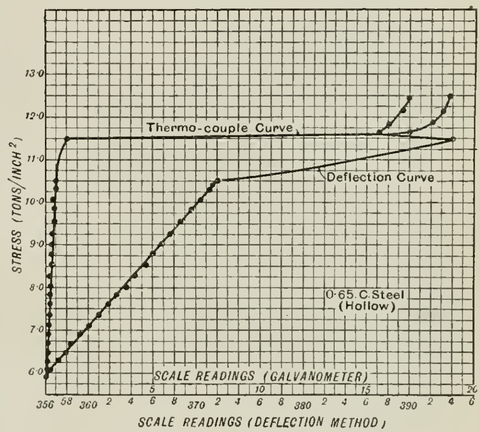
Fig. 7 shows the results of the test on Swedish iron. The material was apparently very unstable up to a certain speed (500 r.p.m.). For the next two increments of speed the strains increased regularly, followed by a definite yield. Subsequently the strains again increased in a regular manner. This result was so unexpected that a second specimen of the same material was prepared. The mass of oscillating weight was reduced so that the breakdown would occur at a higher speed. The curve obtained was very similar to the first. Whether the peculiar shape of the first part of the curve is due to a change in the modulus of rigidity as the stress increases, it is as yet impossible to say.

The following possible, quick method suggested itself for determining the fatigue limit. If the load were increased by increments and the deflection of the end of the cantilever observed, then a deflection-load diagram would probably indicate a "breakdown" point at the fatigue limit. Owing to the fact that the maximum stress occurs only at the one section, the "breakdown" would probably be visible as an "elastic limit" effect rather than as a "yield" effect as in torsion.

A plane mirror was affixed to the non-rotating ball cage and the deflection magnified optically. At each load the image of the filament on the scale was read. It was necessary, owing to the weights employed, to remove the load altogether at four points, with the result that the ball cage fell slightly. The curve at these points was consequently discontinuous, but for the specimen used, the 0.65 per cent carbon steel (as used in the torsion experiments), a departure from the straight-line law was clearly indicated at a point corresponding to a stress of ± 20.74 tons per sq. in. The endurance tests, it will be recalled, had given the fatigue limiting stress as ± 21.0 tons per sq. in.

The experiment seemed to indicate that the method would prove an extremely quick and reliable one for determining the fatigue limit under reversed bending stresses. The apparatus was accordingly modified so that the load could be applied continuously. The mirror was mounted on the specimen and allowed to rotate with it. Fig. 8 shows the new arrangement. A 150-lb. capacity single-lever weighing machine was mounted on top of the Wöhler machine and the load applied by means of an adjustable rod and a stirrup on the outer ball race. Details of the mirror attachment are indicated in the illustration.





Figs. 4 and 5 Curves of Figs. 2 and 3 Replotted to Stress Ordinates

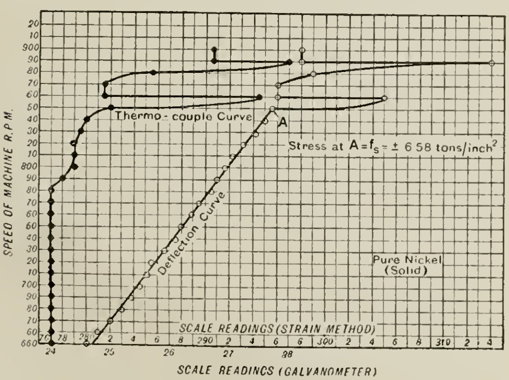


Fig. 6 Thermocouple and Deflection Curve for Solid Specimen of Pure Nickel

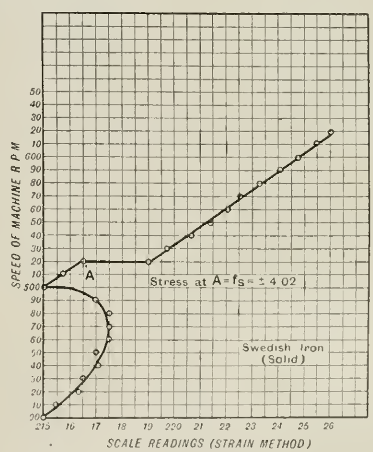

Fig. 7 Deflection Curve for Solid Specimen of Swedish Iron

Four materials have been experimented on using the modified apparatus: 0.65 per cent carbon steel (as used in the torsion tests); pure nickel (as used in the torsion test); a phosphor bronze (ultimate stress 36 tons per sq. in.); and a case-hardening steel. The observations taken from the 0.65 per cent carbon steel are shown plotted in Fig. 9. The other materials gave curves of the same type. The scale readings increase directly with the load until

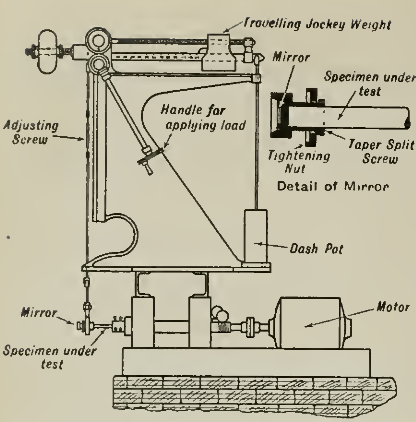

Fig. 8 Modification of Machine Shown in Fig. 1 Adapted for Quick Determination of Fatigue Limit Under Reversed Bending Stresses

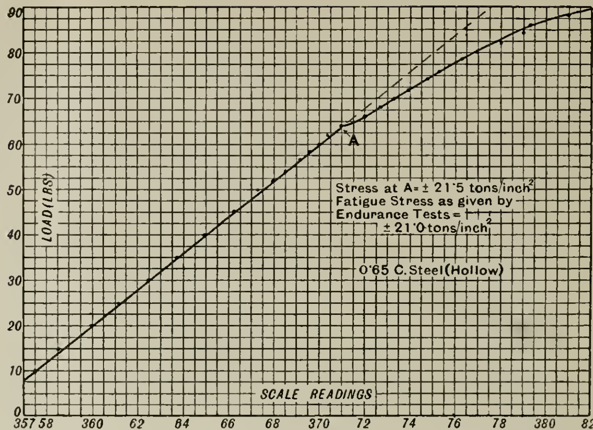

Fig. 9 Deflection Curve for Hollow Specimens of 0.65 per cent Carbon Steel Under Reversed Bending Stress

a certain stress is reached. Here a slight yield occurs. Subsequently the scale readings increase at an increasingly quicker rate than the load.

The stress at which the yield occurs coincides approximately with the limiting fatigue stress as found by the endurance tests.

The fatigue limiting stresses of nickel and the case-hardening steel as found by this new method on a solid specimen agree with the limiting stresses as found by endurance tests on hollow specimens. This fact indicates that the results obtained by this method are independent of the form of specimen used, a very important point, as the cost and difficulty of machining hollow specimens are rendered unnecessary. Table 1 compares the results obtained on the single specimens with those obtained by endurance tests.

TABLE 1 RESULTS OBTAINED ON VARIOUS METALS IN MEASURING FATIGUE LIMIT UNDER REVERSED BENDING STRESSES

Material	Fatigue limiting stress under reversed bending stresses: By deflection method on a single specimen, tons per sq. in.	By endurance tests on six specimens, tons per sq. in.
0.65 per cent carbon steel	±21.5	±21.0
Pure nickel	±13.26	±13.2
Phosphor bronze	±17.2	±17.8
Case-hardening steel	±33.6	±32 to ±35

Six specimens of each material are usually used in the endurance tests. (*The Engineer*, vol. 132, no. 3424, Aug. 12, 1921, pp. 159–162, 13 figs. and 4 tables, *eA*)

Short Abstracts of the Month

CORROSION (See Power-Plant Engineering)

ENGINEERING MATERIALS

Investigation of Physical Properties of Metals at High Temperatures Preceding Their Interval of Plasticity. Data of an investigation carried out under the direction of Professor Cantone in the Laboratory of Experimental Physics of the University of Naples. The investigation carried out by Dr. Mary Kahanoviez has been published in the Proceedings of the Accademia dei Lincei and deals mainly with the question of the transformations which occur in metals as a result of various heat processes. These were deduced from the emission of radiant energy from the metal. It was found that metals follow a simple law of emission which may be expressed by an equation of the type $E = kT^n$, where E is the energy emitted at the given absolute temperature T, and k and n are characteristic constants of the given body. The law of emissivity for oxides of metals is expressed by a more complicated function.

As regards the transformations found, it appears that they differ from oxidations in that they take place with absorption of heat, are reversible and tend in general to make the metal more specular. With nickel, the transformation takes place at between 350 and 370 deg. cent. (662 and 698 deg. fahr), while with iron the point is found around 739 deg. cent. (1346 deg. fahr.). Of particular interest is the case of silver, where the transformation takes place around 770 deg. cent. (1418 deg. fahr.) and has not been discovered by any other method.

The investigation by Dr. Washington Del Regno deals with residual variations in electrical resistance produced as result of heat processes in nickel steels. (*Il Forno Elettrico*, vol. 3, no. 5, May 15, 1921, pp. 71–73, *g*)

Mechanical Properties of Steel at High Temperatures

Universal Steel Classification Code. Horace C. Knerr and Arthur L. Collins. The present system of steel classification known as the S.A.E. system, is believed to be limited in scope and arbitrary rather than scientific.

Nine years ago when the system was inaugurated, alloys were few and the system did not provide for an indefinite expansion in that direction to meet present and future need.

The system was based on the use of numerals, which does not easily permit of expansion. Because of these and some other considerations, a new system was proposed in which letters in addition to numerals were employed, the letter system having the advantage that (omitting O and I) there are 24 available units as compared to nine with numbers. A letter is therefore chosen to represent, or at least suggest, the name of the material in question and numerals are used solely to indicate the quantities. In this way the alloy is expressed in a form somewhat similar to a chemical formula. The only question is whether such a system can be made sufficiently simple to meet practical requirements. The authors claim that it does.

To show how such a system works as compared with the present S.A.E. system the following examples may be cited:

Nickel Steels ("N" Steels)

Proposed	Present
20N1	2120 (1 per cent nickel, 0.20 per cent carbon)
20N2	2220 (2 per cent nickel, 0.20 per cent carbon)
35N3	2335 (3.50 per cent nickel, 0.35 per cent carbon)

Nickel-Chrome Steels ("NK" Steels)

Proposed	Present
20N1K	3120 (1.25 per cent Ni, 0.60 per cent Cr)
30N2K1	3230 (1.75 per cent Ni, 1.10 per cent Cr)
40N3K2	3340 (3.50 per cent Ni, 1.50 per cent Cr)
35N3KX	X3335 (3.00 per cent Ni, 0.80 per cent Cr)

(*The Iron Age*, vol. 108, no. 9, Sept. 1, 1921, pp. 515–517, *p*)

Experimental Investigation of the Mechanical Properties of Steel at High Temperatures, Eugene Dupuy. After a brief historical introduction the author comes to the conclusion that what previous work has shown is that steel at around 300 to 400 deg. cent. (572 to 752 deg. fahr.) exhibits a "blue brittleness," the characteristic of which is that the breaking load is higher and the reduction of area is at a minimum, above which temperature the breaking load gradually falls off and a greater reduction of area is observed reaching its maximum at around 1000 to 1300 deg. cent. (1832 to 2372 deg. fahr.)

An investigation by Rosenhain and Humphrey in 1913 appears to show that the curve indicating the relation between the temperature of the metal and the breaking load has two points of discontinuity which are perfectly well established and a third one which is doubtful.

The present author carried out a series of tests on plain carbon steel with the carbon content varying from 0.15 to 1.23 per cent both in its original state and heat-treated. From these it would appear that as the temperature increases, the breaking load begins to fall off. It is at a maximum of 300 deg. cent. (572 deg. fahr.), or in the region of "blue heat," and from then on it begins to fall

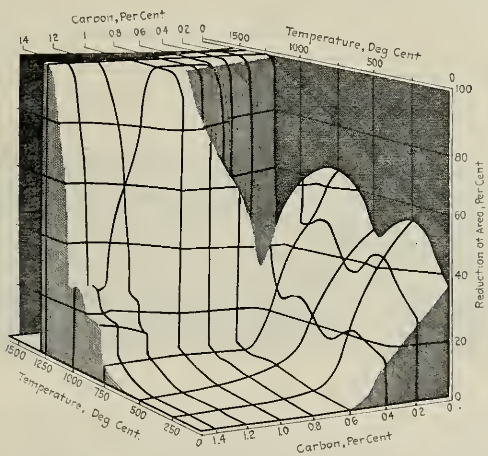

Fig. 1 Temperature-Carbon Content-Reduction of Area Curves for Non-Heat-Treated Ingot Steel

off, showing, however, a slight irregularity from about 450 to 550 deg. cent. (842 to 1022 deg. fahr.) up to a little below 750 deg. cent. (1382 deg. fahr.), the curve in this region having a shape somewhat like the letter U. Thereafter the breaking load decreases again up to the point where liquidus appears and the breaking load suddenly falls to zero. The U characteristic of the curves appears, however, only in hypoeutectoid steels and is absent in eutectoid steels.

These various phenomena are still more apparent in connection with reduction of area. At first there is a slight decrease of reduction of area, reaching a minimum at about 300 deg. cent. (572 deg. fahr.), or a temperature corresponding to the maximum on the curve of breaking loads. Then around 450 deg. cent. (892 deg. fahr.) there is a rapid decrease all the more marked the less ferrite the metal contains. After a short level stretch the reduction of area diminishes slightly and then begins to increase until a temperature of about 775 deg. cent. (1427 deg. fahr.) is reached. From this point on various steels show a different behavior depending on their carbon content. Mild steels show a rapid decrease of reduction of area up to 875 deg. cent. (1607 deg. fahr.). This is followed by a wavy curve with a maximum of 100 per cent at about 1050 deg. cent. (1922 deg. fahr.) which occurs simultaneously with the zero of breaking loads (appearance of liquidus).

The minimum in the region of 900 deg. cent. (1652 deg. fahr.) is the less pronounced the greater the carbon content. In the case of eutectoid steels the curve of reduction of area begins to rise at about 600 deg. cent. (1112 deg. fahr.) and attains 100 per cent at 760 deg. cent. (1400 deg. fahr.)

The behavior of 1.25 carbon steel proved to be different from that of the other steels. From this point of view, Fig. 1 is of considerable interest as showing the relation between temperature carbon content and reduction of area in ingot metal not submitted to any previous heat treatment.

The author divides all carbon steels into the following classes below the A_1, and A_2 as a limit:

Extra mild steel; The ferrite breaks by cleavage before rupture.

Hypo-eutectoid steels: The ferrite alone undergoes noticeable deformation, the rupture taking place when the little islands of pearlite come together.

Eutectoid steels: Rupture practically without deformation.

Hypereutectoid steels: Brittleness due to the presence of cementite.

Austenitic region: No matter what the content of carbon may be, the γ iron is completely plastic.

The region between A_1 and A_2: Plasticity increases with the content of γ iron.

Region between A_2 and A_3: Rupture takes place practically without deformation because of the low content of γ iron and the brittleness of iron in the β region.

Appearance of liquid material: Sudden and simultaneous falling off in the value of the rupturing load and plasticity. (*Revue de Metallurgie*, vol. 18, no. 6, June 1921, pp. 331–365, numerous illustrations, *etA*)

FOUNDRY

Description of Foundry Plant at Warren, Ohio

Continuous Foundry for Pipe Fittings. Henry M. Lane, Mem. Am.Soc.M.E. Description of a foundry plant built at Warren, Ohio, and designed with the view to minimum handling of sand, castings, cores, hot metal and flasks. Only some of the outstanding features will be noted here.

For core making a mixture has been adopted composed of a sharp or lake sand like Michigan City sand, a certain amount of molding sand, and a binder made from waste-liquor refuse from the sulphite paper process. No oil is used. After the mixture is made, it is dropped directly from the bottom of the mixer through a chute into the elevator and passes up to the sand-storage bins over the core room. The secret of the success of this mixture is believed to be largely due to the fact that in a continuous foundry a water-soluble binder may be used as the cores do not remain in the mold long enough to draw dampness.

The production is arranged along the following lines: The molders set out a group of molds at one side of the floor and the pouring gang then comes along and pours this while a group of molds is being put up on the opposite side of the floor. The first group is poured and shaken out and the flasks stacked back before the second group is completed. It is said that they have been able to utilize the floor from four to seven times, depending on the type of work.

In the design of the plant an earnest effort was made to reduce the handling distance to a minimum. It has already been shown how the arrangement of molds minimizes the distance that a molder must carry his molds to set them out. Another economy in distance of handling has been obtained by placing the tumbling bars adjacent to the ends of the casting chutes. The series of casting chutes and the Sly tumbling barrels on the first floor are interspersed. Over the molding floor are a series of underslung cranes with Brillion pouring devices, so that the pouring gang can pour off without the use of hand ladles. The metal is distributed down the gangway in the center by means of monorail. There are other monorails; e.g., one carries the sand from the sand chutes to a bin at the end of the plant, where it is fed to a mixing machine (*The Iron Age*, vol. 108, no. 9, Sept. 1, 1921, pp. 519–524, 10 figs., *d*)

HYDRAULICS

Large High-Head Turbine Unit—Water Leakage and New Labyrinth Seal

Big Creek Development of the Southern California Edison Company. F. H. Rogers. Description of a 30,000-hp. unit designed to operate under a 680-ft. head at a speed of 428 r.p.m., and consisting of a vertical-shaft single-runner Francis type turbine directly connected to a 22,500-kw. 14-pole 50-cycle 11,000-volt generator. The water is led to the turbine through a penstock 2800 ft. long with a diameter of 7 ft. at top and 6 ft. at bottom.

Particular effort was taken to reduce leakage at the runner seals, which is an important factor in the design of high-head units. In this case it is claimed that it is considerably reduced by the use of the Moody labyrinth seal device shown in Fig. 2. In this the leakage water must pass through a series of six seals, at each of which the velocity head is destroyed owing to changes in section and direction of flow. It is claimed that the effective head causing the leakage is only one-sixth of the head for a single seal and that the use of this device will reduce the leakage to only about 0.9 per cent of the full-load quantity, which is about one-third of that which would occur with the single seal.

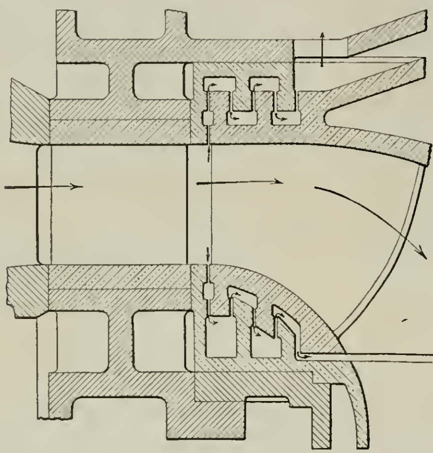

Fig. 2 Section Through Runner of 30,000-Hp. Hydraulic Turbine Showing Labyrinth Seals

As the operation of the unit is continued this leakage loss increases, since the wear at the seals is directly proportional to the velocity of flow through the seals, and as this velocity is about three times as great for the single seal as compared to the labyrinth seal, the wear at the former would be about three times as rapid as for the latter type. It is claimed that after continuous operation for a period of a year the leakage through the labyrinth seal would be only 22 per cent (as compared with 33 per cent for a new turbine) of the leakage occurring with the single seal.

In the usual design of the guide vane there is constant leakage between the top and bottom of the vane and the distributor plates and as this water is not properly guided by the vane it strikes the runner vanes at an incorrect angle causing considerable trouble. The guide vanes in this plant are of the type known as the Overn disk vane (Fig. 3) in which two heavy disks are cast at the junction between the vane and the upper and lower seams. When installed in the turbine the faces of these disks are flushed with the distributor plates so that they prevent any flow above or below the guide vane proper, except for that small portion of the vane which extends beyond the disk. As a result all the water is guided to the runner faces at the proper angle, and when the vanes are in the closed position there is very little leakage.

The original article describes also the draft-tube design, the casting design and the design of the valve.

One of the interesting features of the governor control is the method of change from governor to hand control. In former designs this change usually entailed the closing of three or four large governor valves and the opening of three or four smaller hand-control valves under high pressure. This not only takes considerable time but might lead to serious trouble in case the operator through excitement closes the valves in wrong sequence. In the present installation the governor is furnished with an automatic device known as the Taylor control system, consisting of plunger valves in the governor-base stand operated by oil pressure from the governor system. A single movement of a lever automatically operates all the valves at the same time, closing the governor valves and opening the hand-control valves. (*Power*, vol. 54, no. 7, Aug. 16, 1921, pp. 244–248, 9 figs. *dA*)

Flow of Water Through Galvanized Spiral Riveted Steel Pipe, F. W. Greve. Data of experiments performed in the hydraulic laboratory of Purdue University. The diameters of pipes tested were 4, 6, 8 and 10 in., respectively. The average spacing of the rivets was $^{7}/_{8}$ in. for the smaller and $1^{1}/_{8}$ in. for the larger pipe. The rivet heads on the inside of the pipes projected $^{1}/_{10}$ in. from the pipe wall and were flattened to reduce the resistance to flow.

The relation of friction head per 100 ft. of pipe to velocity of flow both with and against laps, is shown in the original article by a graph. The graphs are straight lines indicating that the head loss varies directly as some power of the velocity. They are nearly parallel lines, which demonstrate that the slope varies but little with the size of pipe. From the figure it also appears that the loss decreases with increase of diameter for any given velocity; that the loss is greater for flow against than with laps and that the difference of loss with and against decreases with increase of diameter. It would appear, therefore, that the flow in large sizes approaches the conditions of smooth pipes.

Fig. 3 Guide Vane of the Overn Disk Type

The friction loss may be expressed as $h_L = mv^n$, where h_L is the loss due to friction expressed in feet of water, v the true mean velocity in feet per second, m the value of h_L when v is 1 ft. per sec., and n is the slope that the graph expressing the relation of h_L to v makes with the horizontal.

The original article gives a table showing certain of the variations of m and n, these relations being of such a character that they are readily established. On the whole it would appear that the friction loss in galvanized spiral riveted steel pipes when the flow is with the laps is little different from that in smooth cast-iron pipes. (*Engineering News-Record*, vol. 87, no. 4, July 28, 1921, pp. 159–160, 3 figs., *e*)

MACHINE TOOLS

Hydraulic Speed Control for Machine Tools

The Oilgear—A Variable Speed- and Feed-Control System for Machine Tools. Description of a speed-control system employing what appear to be some novel devices and permitting a large number of variations of speed and feed without stopping the machine.

The pump unit of the oilgear system comprizes a revolving driver carrying five or seven crossheads and plungers with a corresponding cylinder barrel revolving with the driver and carrying the cylinders in which the plungers reciprocate. By shifting the center of the cylinder barrel the stroke may be varied to suit the conditions to be met. This stroke variation may be met either directly by the

operator or controlled by an outside influence, such as pressure, temperature, centrifugal force, etc.

The motor unit may either be a simple plunger or a revolving multiple plunger unit similar to the pump, except that in the motor the plungers generally have a constant stroke, so that stroke changing mechanism is absent. Because of this the speed of the motor is dependent upon the rate at which the working fluid is delivered by the pump and it varies as the stroke of the pump is increased or diminished.

In addition to this, there is a third unit called the gear pump and acting as a make-up pump for the system. It draws working fluid, which is usually oil from the surplus supply, and keeps several pounds pressure constantly on the intake line of the main pump. It may be also used as a means of rapidly transversing the tool carriage at a speed many times that required for feeding.

The principal unit in the feed-control system is the feed controller, shown in Fig. 4. The controller is essentially a casing including a small variable-delivery pump having a capacity suitable for the small volumes called for in feeding tool carriages, a much larger constant-delivery pump (gear pump) for rapid traverse, a stroke-changing mechanism whereby the operator can accurately set the variable pump-stroke-changing handle, and operating to selectively connect one or the other of the two pumps to the feeding motor according to whether feeding movements or rapid traverse movements are required at the moment.

The plungers are fitted in radial reamed cylinders in the circular cylinder barrel *A*, closely fitted for rotation on a hardened and ground ported pintle *B* and fitted into a swinging arm *C* by means of which the revolving cylinder barrel may be shifted from one side to the other of the revolving driver *D* carrying and operating the plungers. Both driver and cylinder barrel continuously revolve around centers which coincide when the swinging arm is placed in central position and whose distance from one another may be increased in either direction by swinging the arm either to right or left. As the cylinder-barrel axis is moved to right or left the length of stroke of the plunger is correspondingly increased, and results in a flow of oil through the pump in direct ratio to the length of the stroke. This mechanism also gives a reversal of the flow, oil passing through the pump in one direction when the swinging arm *C* is moved to the right, and in the opposite direction when it is moved to the left.

Cam *G* is made with extreme accuracy, giving a speed variation for the tool carriage capable of the finest degree of adjustment. Moreover, after the cam has been swung about through a certain angle it again returns the cylinder barrel to neutral position, thus cutting off the flow from the high-pressure pump and preparing the way for further swing of the control valve which connects the flow from the gear pump to the feed motor, to effect the rapid traverse.

The feed cylinder or motor on a machine tool must have hydraulic fluid on both sides, and the entire system including pipe connections must always be full of fluid under a moderate pressure to exclude air and insure an absolutely steady movement of the tool carriage. The maintenance of this make-up pressure, return of leakage, etc., is an additional function of the gear pump.

Two types of feeding motors are employed—the direct-acting pushing cylinder and the rotary motor. (*American Machinist*, vol. 55, no. 7, Aug. 18, 1921, pp. 271-274, 11 figs., *d*)

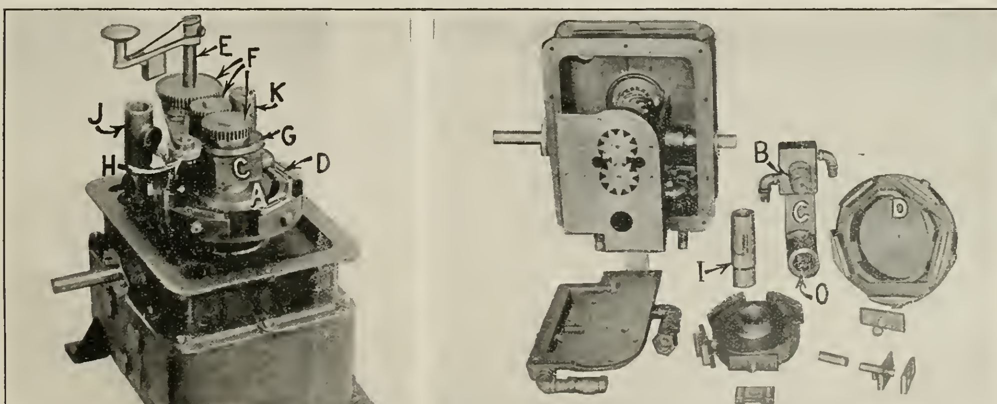

Fig. 4 Control Box with Cover Removed and Its Working Parts

Combination Lathe, Milling and Drilling Machine. Description of a combination machine of American manufacture designed primarily for use in garages, on shipboard and in other places where a rather complete equipment is required and floor space is at a premium (Fig. 5).

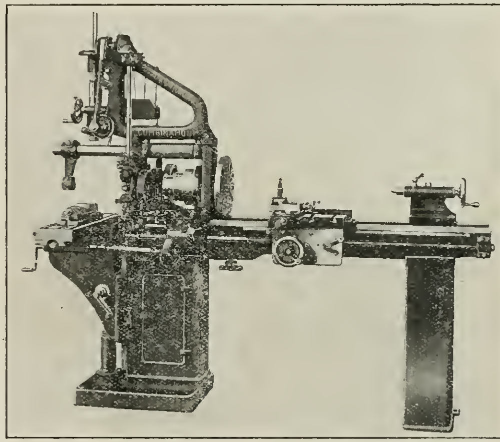

Fig. 5 Combination Lathe, Milling and Drilling Machine

The single hollow spindle serves both the lathe and the milling machine. By removing a section of the shears near the headstock in the lathe it becomes a gap lathe capable of handling face-plate work $18^1/_2$ in. in diameter by $6^1/_2$ in. long, although the lathe itself swings 13 in. over the shears. The removable block is held in place by a tapered dowel bolt.

The drill press can be used only by removing the over arm of the milling machine. A round table is furnished to be attached to the table of the milling machine.

The spindle of the millling machine can be locked rigidly in any position of its vertical travel and it then becomes a vertical milling

machine having all the movement of a standard machine. Handwheel and worm, as well as lever feed is provided for the vertical movement.

While the lathe and drilling machine, or the lathe and drill press, may be used simultaneously, the tool is a one-man machine. Usually it can be set up on a floor space of 40 sq. ft. including the room necessary for the operator to get around it. (*American Machinist*, vol. 55, no. 5, Aug. 4, 1921, p. 202, 2 figs., *d*)

MECHANICS (See Shipbuilding)

POWER-PLANT ENGINEERING

Australian Tests on Condenser-Tube Corrosion

Corrosion in Condensers, Ernest Bate. Data of experience and investigation at the Ultimo and White Bay power houses of the New South Wales Railways at Sydney.

The present experience is that pitting causes failure of about 2 to 3 per cent per year of the Admiralty metal tubes in service in the condensers at White Bay, while at Ultimo very little pitting is now experienced but a certain loss of tubes takes place from end erosion and dezincification. Both power houses draw circulating water from Sydney Harbor, though from different bays, and in both cases the water is liable to the usual contamination from ships, surface drainage, stormwater discharges and factories.

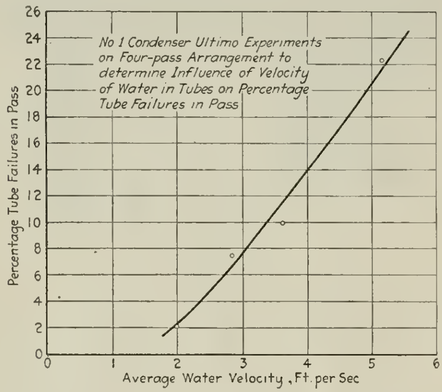

Fig. 6 Influence of Velocity of Water Flow on Erosion of Condenser Tubes

Various kinds of tubes have been used, such as hard-drawn Admiralty mixture brass tubes, practically pure copper tubes, and tubes of patent metal containing about 70 per cent copper and about 29 per cent zinc with small amounts of lead and iron. Formerly tubes tinned inside and out were used, but none have been purchased since 1912 and very few are now in service.

With tubes of similar composition it appears that very different results in the resistance of the metal to corrosion are obtained according to the treatment to which the metal has been subjected.

H. Moore and S. Beckinsale in a paper read before the Sydney Division, Institution of Engineers, Australia, March 10, 1921, stated that almost complete relief of internal stress without softening of Admiralty brass tubes can be obtained by annealing for five hours at 250 deg. cent. (482 deg. fahr.), though the present author shows that annealing of an unsuitable mixture will not enable the metal to give good results in the way of resistance to pitting.

Into one of the units of the White Bay plant, out of a total of 3830 tubes there were placed 342 hard-drawn copper tubes of the composition—copper 99.82 per cent, lead 0.03 per cent, iron 0.04 per cent and arsenic 0.05 per cent. These copper tubes failed by pitting at 80 times the rate of the brass tubes. Within a year about 70 per cent of the copper tubes had become faulty and were removed.

As regards dezincification, trouble was mainly observed with the ferrules. Of tube metal the most liable to dezincification has been found to be a tube of the patented metal above referred to.

Bengough and Jones state that layer dezincification is often associated with acid conditions in fresh water. A phenomenon occurred in No. 1 condenser, Ultimo, while under test, which seems in many respects to be a parallel to this redeposit action, and may help to discover the conditions causing it. This condenser was by accident allowed to remain full of circulating water, and very foul, for about three weeks. When opened at the end of that time a rich deposit, consisting of many pounds of crystal copper in tiny fernlike formation, was found over the tube ends, ferrules, tube plates, and end boxes. No other condensers had ever been found in this condition. It was surmised that the condition of standing foul had caused this effect to be produced, and accordingly the copper was cleaned away by flushing, and the conditions repeated. Ultimately it was found that the redeposit could be obtained by allowing the condenser to stand from two to three weeks, but could not be obtained as a rule for one week. During the standing period both injection and discharge valves on the circulating water main were closed.

A sample of water from the injection pipe close to the waterbox was taken on the first occasion of this redeposit. The water was somewhat dark and rusty in appearance. After filtering, the solution was found to contain—zinc, 3.06 grains per gallon; copper 1.40 grains per gallon; iron, 1.19 grains per gallon; free ammonia (inorganic), 0.192 part per 100,000; albuminoid ammonia (organic) 0.640 part per 100,000.

This water sample was, of course, that furthest from the tubes. The filtered water, on standing in a Winchester quart bottle, steadily threw down a brown deposit, the water near the surface appeared brown, and gradually varied to a faint green tint near the bottom. The deposit on analysis proved to be—copper oxide, 10.6 per cent; zinc oxide, 1.44 per cent; oxide of iron and alumina, 49.32 per cent; insoluble matter, 15.46 per cent; organic matter, 17.93 per cent; combined water, 4.38 per cent; undetermined, etc., 0.78 per cent.

This was not a large condenser. The tubes are mostly tinned and of Admiralty mixture. It is clear that during the standing period copper had passed into solution very freely, that this copper-rich solution had by convection or otherwise appeared at the water box, and had there deposited most of the copper held in solution. The ferrules showed no sign of attack. It seems clear that the condition of the solvent in the tubes was such that the solution pressure of zinc was, for some period at any rate, less than that of copper. Moving to the water boxes this solution of copper underwent a change such that zinc and iron slowly displaced the copper.

An attempt was also made to investigate the influence of velocity of flow on pitting, and it would appear from Fig. 6 that the percentage of failures was about proportional to the square of the velocity of flow. However, the tubes tested were mostly old and the result obtained is regarded purely as indicating the effect of flow in accelerating corrosive effects. The thermal factor appears to be also of importance in this connecton.

An investigation of the influence of intake water particularly as affected by its composition has been started and some data are presented in the original article. (*The Commonwealth Engineer* [Melbourne, Australia], vol. 8, no. 11, June 1, 1921, pp. 339–343, 8 figs., *e*)

Ford's Power Plant May Be Abolished. The enormous power plant at the Ford Highland Park factory, long the pride of Henry Ford, is soon to be transformed from a gas-steam plant to an all-steam plant, or is to be abolished entirely. Engineers, headed by Wm. B. Mayo, are now determining the most economic method of handling the power situation.

The gas-steam plant has been in operation for over ten years and a point has been reached where gas-steam power is no longer as economical as steam power alone.

Two plans are under consideration. The first involves the junking of the producing gas plant and installation of additional steam boilers. This would cost approximately $2,000,000. The second plan is to eliminate the Highland Park power plant entirely and bring high-tension power from the River Rouge, which would require an addition to the latter plant. This cost approximates $3,000,000.

There will be no interference with operations at the Highland Park plant while the power changes are under way. The Detroit Edison Co., which has a power house nearby, would furnish 90 per cent of the present peak power, which runs about 75,000 hp. (*Automotive Industries*, vol. 45, no. 9, Sept. 1, 1921, p. 438)

RAILROAD ENGINEERING

Consolidation Locomotives on the D. & H. and W. M.

High-Capacity Consolidation-Type Locomotives. During the past 10 or 12 years locomotives of the Mikado type have to a large extent displaced Consolidations in heavy main-line freight service. The consolidation is still used to a considerable extent, especially for heavy drag service where slow speeds suffice and fuel conditions do not require the boiler and firebox proportions that can be obtained in the Mikado type. The purchase of 40 heavy Consolidation-type locomotives by the Western Maryland Railway and the use of locomotives of the same type purchased a few years ago by the Delaware and Hudson Company show the vitality of this type. In particular, it is claimed that with driving wheels of the size that are suitable for slow-speed heavy-duty service, it is possible in a Consolidation design to use a firebox throat of sufficient depth to install a brick arch without raising the boiler to an excessive height.

Among the particular features of the new Western Maryland locomotives may be mentioned the following:

The frames are 6 in. wide, spaced 41 in. between centers, and each frame is cast in one piece with a single front rail to which the cylinders are bolted. A substantial steel casting, placed just back of the cylinders, extends the full length of the leading driving pedestals and serves as a fulcrum for the driving brakeshaft. The guide-yoke cross-tie is also of cast steel, and it is extended back sufficiently far to brace the second driving pedestals. This cross-tie also serves as a support for the driving-brake cylinders, one of which, because of the lack of room, is placed in a horizontal, and the other in a vertical, position.

The driving boxes are of cast steel and are fitted with bronze hub faces and brass-lined pedestal faces. Cast-iron shoes and wedges are used, the latter being of the self-adjusting type. The driving axles and engine-truck axle are of heat-treated steel, and flanged tires are used on all the wheels. Flange oilers are applied to the front and back drivers. The ashpan has two hoppers with swing bottoms, both of which are controlled by one handle. Flushing pipes are applied for washing ashes from the slopes of the pan. The injectors and steam turret are placed outside the cab and have extension handles identified by small aluminum plates with raised letters. The equipment includes a breather pipe for providing fresh air while passing through tunnels. This arrangement consists of a 1/2-in. pipe placed across the boiler back head and having five 1/4-in. globe valves equally spaced, each fitted with three feet of 1/2-in. hose. The air supply is drawn from the brake system.

In the Delaware & Hudson Consolidations, the design of the ashpan proved to be quite a difficult problem which was met by the construction of an ashpan having six distinct hoppers and doors. Ample airway for combustion requirements is provided through a 6-in. opening between the pan and the mud ring. The tender construction is unusual for a locomotive of this capacity, in that it is supported upon an underframe of built-up structural shapes with heavy center-sill section, such as is employed in car construction.

In the Delaware & Hudson units the per cent of boiler horsepower to cylinder horsepower is higher than in the Western Maryland (92 as compared with 85 per cent), and this difference is ascribed to the relatively larger percentage of firebox heating surface to total heating surface in the Delaware & Hudson Consolidation, since each square foot of firebox surface is equivalent in evaporating capacity to more than 5 sq. ft. of tubular heating surface. This only serves to emphasize an inherent limitation in the Consolidation-type locomotive. On account of the limited flue length and firebox dimensions, it is impossible to secure horsepower equal to cylinder powerhorse in high-capacity locomotives of this type without the use of thermic siphons or other means of augmenting firebox or tubular heating surface. (*Railway Review*, vol. 69, no. 7, August 13, 1921, pp. 197–205, 15 figs., *d*)

SHIPBUILDING

Gyroscopically Stabilized S.Y. "Lyndonia"

Gyroscopic Stabilization for Ships. Compounded abstract of several articles devoted to the subject of reducing the rolling of a ship by means of gyroscopic stabilization.

E. A. Sperry, Mem. Am.Soc.M.E., points out that in gyroscopic stabilization the roll of a ship is not actually reduced but suppressed by dealing only with its beginnings. All rolling of ships is a gradual accumulation of individual wave increments, and if these single increments are quenched the rolling is done away with.

In the actual construction a little gyro "feeler" (control gyro) detects the incipient roll at its beginning and also shows its direction. From it, through a relay and motor, the large gyro is artificially precessed and delivers stresses of opposite sign to the ship. As a result the ship never starts to roll. The process is said to involve not only a relatively small apparatus but entails merely comparatively small stresses in the hull, said to be from one-sixth to one-tenth those present in a rolling ship.

Alexander E. Schein, Mem. Am.Soc.M.E., in an article entitled, The Gyroscopic Stabilizer on the S.Y. *Lyndonia*, covers practically the same field as the previous article in a much more detailed way.

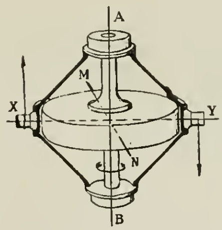

Fig. 7 Simple Gyro Illustrating Precession

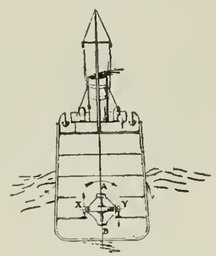

Fig. 8 Elementary Form of Ship Stabilizer

Fig. 7 shows a simple gyroscope which will illustrate the principle of the stabilizer. It consists of a rapidly spinning wheel with axis vertical, mounted in pivot bearings within a vertical ring. There are two trunnions on this ring forming a horizontal axis XY. If the trunnions X and Y are mounted in bearings the whole mass is then free to turn about the horizontal axis XY. Imagine the wheel to be spinning in the direction of the arrow on its rim, and that we apply forces at X and Y. The effect would be to turn the whole mass about a third axis MN. But just here is where the gyroscopic effect comes in. If we assume that the wheel is of sufficient size we can represent forces X and Y by two people, one of whom attempts to lift at X and the other depress at Y. There will be two very evident effects due to gyroscopic action. The first to be noticed is the great resistance the gyroscope offers to any effort to turn it about the axis MN by means of forces X and Y. The second effect is that point A will be seen to move away from us, and point B toward us about the axis XY. These two actions together are known as precession. One is never present without the other. In order to have resisting forces we must have angular movement, and conversely with an angular movement there must be forces. It will be noticed that there are three axes involved in precession. First there is the axis of spin—the axis about which the wheel rotates. Secondly, there is the axis of spin at right angles to the first, about which the forces act. And third, there is the axis of precession about which the gyro turns when forces are applied about the second axis. This third axis is perpendicular to each of the other two. The first axis is represented in Fig. 7 by AB, the second by MN, and the third by XY. Precession may therefore be simply defined as an angular movement accompanied by a resisting moment, both of which are at right angles to the axis of spin and to each other. This principle

is made use of in the gyro ship stabilizer. Just how it is done is evident from Fig. 8, which shows the same gyroscope mounted in a ship. The axis MN is now the axis about which the ship rolls. As soon as there is any angular movement due to rolling, the gyroscope resists it by forces at X and Y, and at the same time precesses about axis XY. If the direction of roll reverses the forces will also reverse and so will the precession about XY. The gyro automatically exerts forces in the proper direction and it is continually oscillating back and forth on the XY axis. In a general discussion about the ship stabilizer the turning movement of the gyro is known as precession, although as defined above precession strictly takes into consideration the forces acting. In this article "precession" will be taken to mean the angular motion of the gyro, and when the forces are referred to, the term will be "gyroscopic force" or "gyroscopic moment." This separation of the two actions simplifies the discussion and is the common practice when speaking of stabilizers.

In Fig. 8 is shown the simplest form of ship stabilizer. In actual design the rotating wheel, or rotor, is mounted in bearings and enclosed in a casing. On this casing there are two gudgeons corresponding to points X and Y through which the forces are transmitted to the ship. It remains only to limit these forces so that they will not be excessive and cause undue stresses in the hull. The well-known formula for gyroscopic moment is:

$$M = \frac{k^2WR}{307}\,n$$

where k^2W is the moment of inertia of the rotor, R the revolutions per minute of the rotor, and n the angular velocity of precession in radians per second. The moment will be in foot-pounds. If we omit the complexity of mathematical expressions the above moment is approximately equal to the tilting moment produced by the maximum effective wave slope, and if such a moment were applied to a non-rolling ship during the period of oscillation it would cause the ship to roll an amount about equal to the maximum roll increment. The stabilizing moment is therefore only slightly greater than the natural effect of the waves causing the ship to roll, and in case of the *Lyndonia* is only about 375,000 ft-lb.

From the formula it is seen that we can control the magnitude of the gyroscopic moment by varying either R or n. It would be impossible to vary R quickly and easily. But with R constant it is an easy matter to vary n and hence M. Stabilizers are therefore designed for some known value of R which will not overstress the wheel, and the gyroscopic forces transmitted to the ship limited by limiting the speed of precession by mechanical brakes or other means. This type of stabilizer is known as the passive gyro stabilizer. It uses the forces of the waves to start gyro precessing, and mechanical brakes suitable pistons and levers to control within close limits the speed of precession. Due to the fact that the mass of the casing and wheel is necessarily large it takes several seconds to get the speed of precession up to normal velocity, and therefore the ship has gained considerable roll before full stabilizing is obtained. The passive-type stabilizer cannot decrease the roll to less than six or seven degrees.

Mechanical details of construction of the *Lyndonia* stabilizer are given in an article by W. T. Manning, while the electrical equipment is described by T. P. Kirkpatrick and H. C. Coleman. (*The Electric Journal*, vol. 18, no. 8, Aug. 1921, pp. 335–349, illustr., *dA*)

CLASSIFICATION OF ARTICLES

Articles appearing in the Survey are classified as *c* comparative; *d* descriptive; *e* experimental; *g* general; *h* historical; *m* mathematical; *p* practical; *s* statistical; *t* theoretical. Articles of especial merit are rated *A* by the reviewer. Opinions expressed are those of the reviewer, not of the Society.

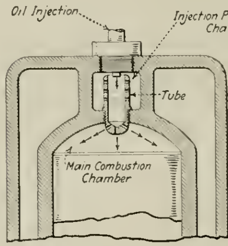
From information published in some of the British motor papers it would appear that the famous German Mercedes motor works, which during the war have built many of the German aircraft motors, are now working on a supercharged type of engine for automobiles and trucks. The president of that company states, though, that only very slight increases in power can be obtained by applying the principle of superinduction without a complete re-design of the motor.

IMPORTANCE OF OIL-INJECTION TYPE OF INTERNAL-COMBUSTION ENGINE

(*Continued from page 658*)

form, by Nielsen, who also provided for adjustment of injection-chamber volume by a special cover or cap.

Still another type brought out in the course of development of the divided combustion chamber is the Leissner, Fig. 23. Leissner adds to the Nydahl or Neilsen injection chamber a tube which has holes in the sides and bottom to form the old-fashioned fuel distributor used with air- and solid-injection spray valves. The Leissmer tube comes up close to the injection spray nozzle which delivers the oil inside the tube. Just as the small injection chamber alone prevents development of explosive shocks by limited contact of air and fuel, so does insertion of this tube add something to further limit the contact control. Leissner specifies that the holes through the bottom and sides of the tube, and the space above it, shall be so related to each other in area as to produce the following series of actions: Compression carried first to ignition temperature; injection inside the tube in the injection chamber and partial combustion in the tube, producing a rise of pressure in the tube, which in turn projects jets of still unburned oil sidewise into the air around the tube. Combustion of these jets raises the pressure outside of the tube and causes reversal of flow back into the tube and down through it to the cylinder, helped by the movement of the piston; the air left around the tube finally passing through the tube and expelling the fuel charge in front of it into the cylinder, the space around the tube and in the tube being in series. This



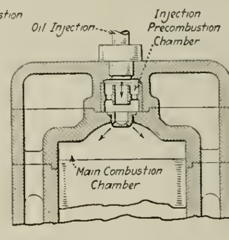


Fig. 23 Leissner Divided Cold Combustion Chamber
Fig. 24 Worthington Divided Cold Combustion Chamber

is a new engine brought out in Sweden, and it is now being introduced into this country.

Finally, in this class of divided-combustion-chamber injection engines there is a new one developed by Worthington—the class in which the injection or precombustion chamber is used to limit the development of explosive shocks and connected to the cylinder by an ejection orifice through which gasified fuel is expelled to the cylinder by a pressure differential due partly to the movement of the piston and partly to the precombustion. This is shown in Fig. 24. It has a tube open at both ends and supported from the side walls with wide spaces at each end. The bottom of the injection chamber has a passage to the cylinder of the usual fuel-distributing sort, forming a fuel-ejection orifice. There are large holes through the tube-supporting web, so that the injection chamber acts as a single chamber, with the tube acting as a sort of fuel baffle or guard. The charge being injected into the tube is limited by the tube as to air contact. The tube constitutes a fuel guard, by means of which the amount of precombustion can be controlled and at the same time the fuel is gasified in the hot limited amount of air. A rise of pressure in the injection chamber, due to partial combustion, is suppplemented by depression of the pressure on the cylinder side due to the piston movement, which starts the flow of parallel streams of air and fuel toward the cylinder. This action creates in effect a bunsen burner in the top of the cylinder. This arrangement gives a construction practically as simple and foolproof as the little Hvid, except for the injection pump, but one that seems to be adapted to a wider range of cylinder sizes and speeds and less limited by fuel quality.

Much experimental research has already been completed and more is planned, to be presented in a later paper.

ENGINEERING RESEARCH

A Department Conducted by the Research Committee of the A.S.M.E.

A—Research Results

The purpose of this section of Engineering Research is to give the origin of research information which has been completed, to give a résumé of research results with formulas or curves where such may be readily given, and to report results of non-extensive researches which, in the opinion of the investigators, do not warrant a paper.

Aircraft A3-21. Air Propellers. The work of Prof. W. F. Durand and E. P. Lesley on (*a*) air screws in yaw and (*b*) a general analysis and résumé of the results of detailed investigations of 88 air-propeller models for the determination of the general laws covering the entire series has been completed and submitted to the National Advisory Committee for Aeronautics. Address Prof. W. F. Durand, Leland Stanford Junior University, Stanford University, Cal.

Apparatus and Instruments A8-21. Tearing Instruments and Tests for Paper. Technologic Paper 194 of the Bureau of Standards may be obtained from the Superintendent of Documents, Washington, D. C. at 5 cents per copy. The paper reports the study of the effect of different sizes of test samples on tearing strength of paper. It has been found that the larger the sample the greater the value of the tearing strength owing to fabric assistance. One instrument is used for tensile strength and two instruments for tearing strength. It was impossible to calibrate one type of tearing instrument because of friction in certain parts of the mechanism. The other was accurate within 5 per cent. Bureau of Standards, Washington, D. C. Address S. W. Stratton, Director.

Cement and Other Building Materials A10-21. Fire Tests on Building Columns. The fire tests on building columns reported previously were made at the Underwriters Laboratory at Chicago, Ill. The report of these tests is found in a publication which may be obtained at $2 per copy in paper covers and $2.50 per copy in cloth covers from the Associated Factory Mutual Fire Insurance Companies at 31 Milk St., Boston, Mass., or at the Underwriters Laboratories, 207 East Ohio St., Chicago, Ill. The report covers 389 pages and contains the following sections:

1 Introduction
2 Description of Columns
3 Schedule of Tests
4 Placing of Covers and Concrete Columns
5 Auxiliary Tests of Materials
6 Description of Furnace and Related Equipment
7 Temperature Measurements
8 Deformation Measurements
9 Method of Testing
10 Results of Fire Tests
11 Results of Fire and Water Tests
12 General Summary and Discussion
13 Fire Resistance Periods from the Test Results

The appendices give various data, including photographs of the columns before and after testing, curves of temperature and time and curves of deformation and average temperature.

There were 106 tests of columns, of which 91 were fire tests and 15 fire-and-water tests. The fire tests included tests of representative types of unprotected structural steel, cast iron, concrete-filled, pipe and timber columns; columns with metal partially protected with concrete, columns with 2-in. or 4-in. thickness of concrete, tile, brick, gypsum block or plaster as a protection, and reinforced-concrete columns with 2 in. of integral concrete protection. Materials used for protection and the constituent materials were tested. The columns were designed for a working load of approximately 100,000 lb. and the load was maintained constant during the test. Measurements were taken of temperature of furnace and the deformation due to the load when heated. In the fire-and-water test the columns were loaded and exposed to the fire a predetermined time. Address Underwriters Laboratories, 207 East Ohio St., Chicago, Ill.

Cement and Other Building Materials A11-21. Fire Test of Brick Panels. A fire test of 8-in. solid restrained panel of eastern brick and two tests on 8-in. hollow unrestrained panels, one of eastern and one of western brick, were made at the Bureau of Standards during July. Except for the fact that the eastern brick did not fuse on the exposed side during test, no difference was noted in the two kinds of bricks. No collapse occurred. Bureau of Standards, Washington, D. C. Address S. W. Stratton, Director.

Cellulose and Paper A2-21. Tearing Instruments and Tests. See *Apparatus and Instruments A8-21.*

Fuels, Gas, Tar and Coke A13-21. Iowa Coals. Technical Paper 269 on Analysis of Iowa Coals by George S. Rietz, A. C. Fieldner and F. D. Osgood, includes the geology of the coal beds, the coal resources, the character of the coal, development and transportation, uses, fusibility of ash, coking properties, markets, future developments and chemical analysis. The paper ends with list of publications on the composition of coal. Bureau of Mines, Washington, D. C. Address H. Foster Bain, Director.

Fuels, Gas, Tar and Coke A14-21. Water-Gas Apparatus. Water-Gas Apparatus and the Use of Central District Coal as Generator Fuel is the subject of Technical Paper 246 of the Bureau of Mines. The paper was prepared under a coöperative agreement with the Illinois State Geological Survey and the Engineering Experiment Station of the University of Illinois. The paper describes modern apparatus, distribution of heat, blasting reactions, requisites for efficiency, production of coke and coal as generator fuel, design of generator set, depth of fuel, and closes with a list of publications on producer gas. Bureau of Mines, Washington, D. C. Address H. Foster Bain, Director.

Internal-Combustion Engines A4-21. Fuel Economy. The Bureau of Standards has investigated the effect of introducing exhaust gases with the explosive mixtures for a gas engine for the purpose of obtaining a high compression ratio for low powers. An engine was operated with the leanest air-fuel ratio which would ignite regularly and it was again operated with a sufficient amount of exhaust gas with a charge to reduce the engine power to the same value as had been obtained in the first test by throttling. Although the pressures in the latter test were considerably higher than in the first test, the limiting air-fuel ratio for firing was not as great and a lower thermal efficiency resulted. It seems fair to conclude that the dilution of the charge by the spent gas makes it impossible at low throttles to employ the air-fuel ratios which give maximum efficiency. Bureau of Standards, Washington, D. C. Address S. W. Stratton, Director.

Machine Design A3-21. Strength of Screw Fastenings in Plywood. It is important that size of screw spacing and margin of screw fastenings in plywood should be adapted to the species and thickness of plywood used. The Forest Products Laboratory has found that commonly used plywoods are divided into the following groups:

Group I, Low Density		Group II, Medium Density		Group III, High Density
Basswood	Hemlock	Ash, black	Hackberry	Ash, white
Cedar, Spanish	Pine, sugar	Ash, pumpkin	Magnolia	Beech
Cottonwood	Pine, white	Elm, white	Mahogany	Birch
Cypress, bald	Poplar, yellow	Gum, black	Maple, soft	Cherry, black
Douglas fir	Redwood	Gum, cotton	Sycamore	Elm, cork
Fir, true	Spruce, Sitka	Gum, red	Walnut, black	Maple, hard

The data regarding screws are found in the following table, the gage being the smallest that can be used with the thickness specified and not cause failure through breaking of the screws when full strength of plywood is developed and the length being the shortest that will prevent the screw pulling out before the full strength of the wood is reached. The margin is the minimum margin for full development of strength.

Species of plywood	Thickness of plywood, in.	Gage (Number) of screw	Screw length, in. Species receiving point: White ash	Spruce	Margin, in.	Spacing, in.
Group I	3/30	4	1/2	5/8	1/2	3/8
	3/24	5	1/2	5/8	5/8	1/2
	3/20	6	5/8	3/4	5/8	1/2
	3/16	7	5/8	3/4	5/8	5/8
	3/10	9	3/4	1	3/4	3/4
	3/8	11	1	1 1/4	3/4	3/4
Group II	3/30	5	1/2	5/8	1/2	1/2
	3/24	6	5/8	3/4	5/8	1/2
	3/20	7	3/4	7/8	5/8	5/8
	3/16	8	7/8	1	5/8	3/4
	3/10	10	1	1 1/4	3/4	3/4
	3/8	12	1 1/4	1 1/2	3/4	7/8
Group III	3/30	6	5/8	3/4	1/2	1/2
	3/24	7	3/4	1	5/8	5/8
	3/20	8	1	1 1/4	5/8	3/4
	3/16	9	1 1/4	1 1/2	5/8	3/4
	3/10	11	1 1/2	1 3/4	3/4	7/8
	3/8	13	1 3/4	2	3/4	1

Equally good results were obtained with flat-headed screws without washers and round-headed screws with washers. Round-head screws without washers proved an inferior means of fastening. The spacing given in the table is for screws in a single row, but staggering is recommended when possible. The tests were made without reference to the member to which the plywood was attached. Until further information designers must take care that the frame is not split or weakened through the use of the size of screw and spacing necessary to make the fastening as strong as the plywood. U. S. Forest Products Laboratory, Madison, Wis. Address Director.

Metallurgy and Metallography A14-21. Graphitization in Cast Iron. The microscopic study of various specimens of cast iron after prolonged annealing indicates that considerable change in the combined carbon occurs below the thermal critical range (about 700 deg. cent.). This graphitization does not occur below 500 deg. cent. after a very prolonged heating period. The microscopic study reveals many interesting and valuable facts not shown by chemical analysis alone. In

low-temperature graphitization only the pearlite is not affected. The free carbide does not appear to change until the thermal critical point has been passed and the solution of this constituent has begun. The form in which the graphite exists after annealing depends on initial structure. If flakes of graphite exists they act as nuclei for the deposition of the graphite formed during annealing. If no flakes are present the graphite takes the form of small globules. The data from furnace work, chemical analysis and microscopic examination are being put in shape for publication for a supplement to Technologic Paper 129. Bureau of Standards, Washington, D. C. Address S. W. Stratton, Director.

Metallurgy and Metallography A15-21. TEMPERING HARDENED STEELS. An investigation on the structural changes occurring in hardened steels upon tempering has progressed far enough to show that there is a decided change brought about by tempering at approximately 240 deg. cent. Up to that temperature no structural change is to be seen. In all cases the changes which occur are relatively inconspicuous and this accounts for the lack of data relating to this subject. Bureau of Standards, Washington, D. C. Address S. W. Stratton, Director.

Mining, General A6-21. VENTILATION IN METAL MINES. Technical Paper No. 251 by Daniel Harrington is devoted to a preliminary report on ventilation in metal mines. The bulletin explains the method used in determining the physical data as a basis of the paper and then describes the elements which control metal-mine ventilation. It also describes the conditions effecting the temperature of mine air, relative humidity of mine air and the composition of mine air, giving the effect of dust and velocity, as well as methods for providing efficient ventilation, with its control and cost. A list of publications of the Bureau of Mines dealing with mine gases and mine ventilation is appended. Bureau of Mines, Washington, D. C. Address H. Foster Bain, Director.

Mining, General A7-21. ACCIDENTS IN METAL MINES. During the calendar year 1919 the number of operators reported to the Bureau of Mines was 145,262. The average employment of these men was 281 days per year per man. The number of men killed was 468 and the number of men injured was 31,506. The report shows that for every thousand men employed for 300 working days 3.31 were killed and 231.8 injured enough to cause them to lose at least one day's time. This is the lowest record of fatality in the metal-mining industry of the United States and the injury rate is lower than any year since 1914. Bureau of Mines, Washington, D. C. Address H. Foster Bain, Director.

Mining, General A8-21. COAL-MINE FATALITIES. Technical Paper No. 228 of the Bureau of Mines states that during 1920, 2260 men were killed in the coal mines of the United States, a decrease of 57 from the record of the year before. This reduction occurred with an increase of 18 per cent in the output of coal. 3.50 lives were lost for every million tons of coal in 1920, while in 1919 there were 4.24 lives lost. In 1920 there were 775,000 men employed in mines while in 1919 the number was 765,000. The total production of coal was 645,663,000 tons, of which more than five-sixths was bituminous coal. There was a decrease of 64 per cent in fatalities due to fires, a decrease of 38 per cent in fatalities due to explosives and a decrease of 14 per cent in deaths resulting from the explosion of gas and coal dust. This bulletin includes a list of permissible explosives, lamps and motors and gives a list of certain approved mine-rescue apparatus. It gives a list of state mine inspectors and other mine officials. Bureau of Mines, Washington, D. C. Address H. Foster Bain, Director.

Railway Rolling Stock and Accessories A1-21. STRESSES IN CAR WHEELS. Special runs on car wheels were made in which strain measurements in radial and tangential directions on both faces of the wheel were taken. Results indicate that no tangential stresses are set up in the wheel as a result of heating. On the front side of the wheel tension exists near the hub and compression near the rim, while stresses of equal magnitude but of opposite sign exist on the other side. The stress distribution appears to be a result of the shape of the wheel. Similar tests will be made on wheels from each of the other manufacturers. Bureau of Standards, Washington, D. C. Address S. W. Stratton, Director.

Steam Power A2-21. STEAM CONSUMPTION OF TURBINES. Carroll Stansbury and Louis Weil have determined that the steam consumption of a steam turbine may be found by measuring the quality of the steam at entrance to and discharge from a turbine. From the steam tables the heat contents at the two points may be found and from these the water rate is given by

$$w = \frac{2546.5}{F\,(H_1 - H_2)}$$

where w = lb. of steam per hp-hr.
F = factor = $p/(p + pf)$
H_1 = heat content at entrance for observed pressure and quality
H_2 = heat content at discharge for observed pressure and quality
Steam should be superheated at both points for simple measurement of quality.
p = horsepower developed by turbine
pf = horsepower equivalent to heat in radiation residual velocity and mechanical friction

$$= \frac{K}{2546.5}$$

where $K = w_0\,(H_{01} - H_{02})$
w_0 = steam consumption per hour at no load.
H_{01} = heat content at entrance, no load
H_{02} = heat content at discharge, no load.

Tests of this method have shown very close agreement with practice. Johns Hopkins University, Baltimore, Md. Address Prof. A. G. Christie.

Wood Products A6-21. STRENGTH OF SCREW FASTINGS IN PLYWOOD. See *Machine Design A3-21.*

Wood Products A7-21. GLUE STAINS. Casein and vegetable glues containing caustic soda produce stains on certain woods such as oak, maple, cherry, elm, ash, birch and beech. This is due to the action of the alkali on the tannins and other constituents of the wood whereby an inky substance is formed. No means can be found to prevent this chemical action. Precaution will keep the discoloration from the finished surface. If veneers are less than $^1/_{20}$ in. thick, glue will seep through pores, hence thicker glues are used with fillers added when staining is feared. If a panel is dried promptly the caustic soda will have difficulty in coming to the surface. Rapid drying by removing panels from press as soon as possible and placing them on stickers is advisable. These stains can be removed by sponging the stained surface with a solution prepared by dissolving one ounce of oxalic acid crystals in 12 ounces of water. Still better results may some times be obtained by first moistening wood with sodium sulphite solution of similar concentration to the oxalic solution. U. S. Forest Products Laboratory, Madison, Wis. Address Director

Wood Products A8-21. SUBSTITUTES FOR ASH. The Forest Products Laboratory has published Technical Note 147 showing how maple, elm, birch, hickory, red gum, oak and Southern yellow pine may replace ash for certain parts of automobile bodies. The note gives the relative values of these different woods in terms of ash as per table below.

U. S. Forest Products Laboratory, Madison, Wis. Address Director.

SPECIES	Strength as a beam or post	Stiffness	Shock-resisting ability	Hardness
Ash, white, forest-grown..	100.0	100.0	100.0	100.0
Ash, black...............	71.3	79.3	90.1	62.3
Ash, white, second-growth	122.5	117.6	119.6	118.9
Basswood...............	59.1	80.6	40.5	29.6
Beech..................	93.5	96.9	96.0	90.0
Birch, yellow...........	104.8	116.8	120.6	80.9
Chestnut...............	66.0	71.9	53.4	49.2
Cottonwood.............	60.6	79.0	54.3	35.3
Cucumber..............	85.4	112.4	76.7	54.9
Elm, rock or cork........	98.8	92.9	140.5	101.6
Elm, white..............	79.2	79.5	89.5	57.1

B—RESEARCH IN PROGRESS

The purpose of this section of Engineering Research is to bring together those who are working on the same problem for coöperation or conference, to prevent unnecessary duplication of work and to inform the profession of the investigators who are engaged upon research problems. The addresses of these investigators are given for the purpose of correspondence.

Air B5-21. REHEATING. The effect of internal- and external-combustion air reheaters and the thermodynamic efficiencies secured through the use of reheated air in air motors is being investigated by Dean C. R. Richards and J. N. Vedder. Three types of reheaters were tested and also steam was used as the reheating agent. The reheated air is used in a small Corliss engine, the load being adjusted to give complete expansion. The results so obtained were compared with those when cold air was used. Address Dean C. R. Richards, Engineering Experiment Station, University of Illinois, Urbana, Ill.

Automotive Vehicles and Equipment B6-21. COST OF OPERATING TRUCKS. The Automobile Section of the Mechanical Engineering Laboratory of the University of Michigan is calibrating several four-ton trucks so that the Highway Department can determine economical data regarding trucks in service. These trucks are being calibrated to determine the losses in the engine, in the transmission system from engine to bearings and differential gears and to determine the power required to roll the truck along the level road on various grades with different loads. In doing this the truck is brought into the laboratory and the engine placed on a testing stand to determine horsepower, fuel economy and mechanical efficiency. The manifold suction is observed for every run. The engine is then replaced in the truck which has been mounted between two dynamometers with axle jackshafts connected to the armature shafts of the dynamometers. The engine is then run at a speed and manifold suction corresponding to one of the runs on the engine stand. The power output of the transmission is then determined and from the previous calibration of the engine alone the efficiency of the transmission system is then determined. The truck is then operated on the road with different loads and on different grades by pulling it

will then be operated on various grades and at various loads and the fuel consumption measured at different stations at about 100-ft. intervals. University of Michigan, Ann Arbor, Mich. Address W. E. Lay.

Boilers and Accessories B1-21. Super Boiler Test. The Detroit Edison Company is making a test on one of its large boilers at the Connors Creek plant. This test will cover a period of about ten weeks. The purposes of this test are:

1 To determine the most economical coal with particular reference to the ash content of the coal

2 To determine how many improvements can be made in the present baffle arrangement.

3 To determine the relation between frequency of blowing the flues and economy, and

4 To determine the banking losses of the boiler.

Detroit Edison Company, Detroit, Mich. Address Paul W. Thompson.

Cement and Other Building Materials B2-21. Concrete. A number of researches have been planned by Prof. A. N. Talbot on the measurement of mobility of fresh concrete and a general investigation of concrete and one on the effects of graduating the particles of the aggregate as well as varying the amount of water and cement in making the mixture. It is planned to determine the proper quantity in a mixture to obtain a workable concrete, to find the effect of storage of test specimens, the method of capping, the effect of moisture when tested, the effect of age, the effect of time of removal from mold, the strength of concrete specimens cut from various portions of a structural member or from a pavement to determine the effect of different elements entering a mixture of concrete, and lastly, to find the effect of various sands on the effect of concrete. Address Dean C. R. Richards, Engineering Experiment Station, University of Illinois, Urbana, Ill.

Fuels, Gas, Tar and Coke B3-21. Ignition Point of Fuels. The ignition point of fuels is being investigated by Prof. H. H. Stoek and R. W. Arms by observing the action of coal when gradually heated. Address Dean C. R. Richards, Engineering Experiment Station, University of Illinois, Urbana, Ill.

Fuels, Gas, Tar and Coke B4-21. Dewatering Coal Slime. H. F. Yancy and Thomas Fraser, under the direction of the U. S. Bureau of Mines, are investigating the dewatering of coal slimes, conducting experiments at the filter plant in Urbana in connection with the sludge work of the state water supply. Address Dean C. R. Richards, Engineering Experiment Station, University of Illinois, Urbana, Ill.

Fuels, Gas, Tar and Coke B5-21. Coal Washing. H. F. Young and Thomas Fraser are investigating the washing of coals of different kinds and under different conditions and also the separation of pyrite and organic sulphur by washing with jigs and tables. Address Dean C. R. Richards, Engineering Experiment Station, University of Illinois Urbana, Ill.

Fuels, Gas, Tar and Coke B6-21. Sliding Friction. Professors Stoek and Holbrook are determining the sliding friction of bituminous coal and the subsidence used for chutes in conveying coal. Address Dean C. R. Richards, Engineering Experiment Station, University of Illinois, Urbana, Ill.

Heat B21-21. Buried Pipe. An investigation to determine the temperature gradient of heat flow from steam pipe buried in ground to surrounding earth in connection with the fellowship of Ric-wil Company is being continued at the University of Michigan. Thermocouples are distributed in a plane normal to the pipe and one or two readings are taken a day. At the same time the pressure and quality of the steam is observed. University of Michigan, Ann Arbor, Mich. Address J. E. Emswiler.

Machine Design B5-21. Stresses in Boiler Heads. Prof. G. A. Goodenough is investigating the stresses in boiler heads. Address Dean C. R. Richards, Engineering Experiment Station, University of Illinois, Urbana, Ill.

Mechanics B4-21. Web Stresses in Beams. Prof. A. N. Talbot and others are investigating the web stresses in beams to determine the best method of reinforcing beams to take diagonal tension stress. Stirrups and bent-up bars are used in various proportions, amounts and spacings, tests being made with steel gages on both samples and restrained beams. Address Dean C. R. Richards, Engineering Experiment Station, University of Illinois, Urbana, Ill.

Mechanics B5-21. Reinforced-Concrete Columns. An investigation by the use of the strain gage on the reinforcement to determine the strains in the reinforcement and the action of the spiral reinforcement. The investigation will include the effect of pitch, spiral length of column, eccentricity, richness of concrete and longitudinal reinforcement as well as frictional resistance of granular material restrained by hooping. Address Dean C. R. Richards, Engineering Experiment Station, University of Illinois, Urbana, Ill.

Railway Rolling Stock and Accessories B4-21. Journal Friction. A considerable amount of data has been collected on friction of railroad-car journals in relation to and as a component part of the resistance of trains. The investigation will include the analysis of existing information and the analysis of data possessed by the Railway Engineering Department of the University of Illinois as well as additional test results obtained by the railway electrical test car. Address Dean C. R. Richards, Engineering Experiment Station, University of Illinois, Urbana, Ill.

The method of reducing the pounding of trolley cars and the possibility of increasing the pressure between the trolley wire and collector with increased speed of car has been undertaken by J. K. Tathill under the direction of Prof. J. N. Snodgrass. This work is being done with the electrical test car of the University of Illinois. Address Dean C. R. Richards, Engineering Experiment Station, University of Illinois, Urbana, Ill.

Railway Rolling Stock and Accessories B6-21. Tractive Effort. An investigation has been begun under the direction of Prof. J. N. Snodgrass to determine the values of locomotive tractive effort. Address Dean C. R. Richards, Engineering Experiment Station. University of Illinois, Urbana, Ill.

Transportation B1-21. Wire-Rope Fastenings. The strength of wire-rope fastenings including clips, clamps, sockets and other devices, is to be investigated at the Ohio State University for the Director of Safety of the State of Ohio. Ohio State University, Columbus, Ohio. Address Prof. W. T. Magruder.

C—Research Problems

The purpose of this section of Engineering Research is to give notes of a personal nature regarding the personnel of various laboratories, methods of procedure for commercial work or notes regarding the conduct of various laboratories.

Transportation C1-21. Wire-Rope Fastenings. To aid the Engineering Experiment Station of the Ohio State University to publish a report on the Strength of Wire Ropes and Their Fastenings, information regarding results of tests or information regarding reports on this subject is greatly desired. The questions which have arisen are as follows:

1 What are the relative strengths of wire-rope eyes, or loops, made up with clips and clamps, and of wire ropes with sockets of various kinds and constructions, as compared with the rope itself, either spliced or tested over sheaves?

2 Sockets are usually considered to be a permanent fastening, but when should clips be used rather than clamps?

3 How should they be applied? How tightly should they be drawn up?

4 What effect has the size of the thimble on the strength of the rope?

5 How many fastenings should be used on each loop or eye?

Ohio State University, Columbus, Ohio. Address Prof. W. T. Magruder.

D—Research Equipment

The purpose of this section of Engineering Research is to give in concise form notes regarding the equipment of laboratories for mutual information and for the purpose of informing the profession of the equipment in various laboratories so that persons desiring special investigations may know where such work may be done.

University of Alabama E1-21. The Legislature of the State of Alabama has created a special School of Mines fund of $25,000 per year for four years to be used in coöperative work with the U. S. Bureau of Mines, the Bureau of Mines to provide equal funds. As a result a thoroughly modern mining and ore-dressing laboratory for the School of Mines of the University of Alabama has been installed. Five fellowships are to be offered during the coming year. These are open to graduates of universities and engineering schools. The value of each fellowship is $540 per year of nine months. The following subjects are to be investigated during the coming year:

1 Beneficiation of iron ores.

2 The preparation, treatment and uses of non-metallic minerals such as barite and ocher in industries other than ceramic or chemical industries.

3 Metallurgical coke.

University of Alabama, University, Ala. Address Prof. H. D. Pallister.

E—Research Personnel

The purpose of this section of Engineering Research is to give notes of a personal nature regarding the personnel of various laboratories, methods of procedure for commercial work or notes regarding the conduct of various laboratories.

F—Bibliographies

The purpose of this section of Engineering Research is to inform the profession of bibliographies which have been prepared. In general this work is done at the expense of the Society. Extensive bibliographies require the approval of the Research Committee. All bibliographies are loaned for a period of one month only. Additional copies are available, however, for periods of two weeks to members of the A.S.M.E. These bibliographies are on file at the office of the Society

Transportation F1-21. Wire-Rope Fastenings. A bibliography of two pages on Wire Ropes, Clips, Clamps and Sockets. Search 3411. Address Arthur M. Greene, Jr., Rensselaer Polytechnic Institute, Troy, N. Y.

CORRESPONDENCE

CONTRIBUTIONS to the Correspondence Department of MECHANICAL ENGINEERING are solicited. Contributions particularly welcomed are discussions of papers published in this Journal, brief articles of current interest to mechanical engineers, or suggestions from members of The American Society of Mechanical Engineers as to a better conduct of A.S.M.E. affairs.

The Question of Entropy

TO THE EDITOR:

Professor Goldman's demonstration on page 621 of MECHANICAL ENGINEERING for September that "Entropy is a complete error" is interesting but not convincing. In his notation he says that H denotes the heat energy. If we knew precisely what heat energy is under consideration, it would be easy to point out the fallacy in the demonstration; not knowing which of the various heat energies H stands for, we must examine each of the possible cases.

In thermodynamics there are three thermal magnitudes that demand attention:

1 Q, the heat absorbed by a system when it changes state
2 U, the intrinsic energy of the system
3 I, = V + $(pV/778)$.

This last quantity, I, is one of the so-called thermodynamic potentials devised by Duhem, Gibbs, and others in the consideration of the equilibrum of thermodynamic systems. The intrinsic

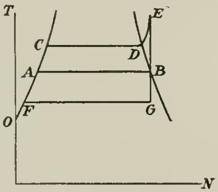

FIG. 1

energy U, which is due to the molecular motion and molecular configuration of the system, is fixed by the state of the system; that is, the change of U between two states is independent of the path followed. Evidently, therefore, since the product pV is fixed by the state, the value of the potential function I is likewise determined solely by the state of the system.

On the other hand, the quantity of heat Q absorbed by the system in a change of state depends on the path. Thus:

$$Q = \text{increase of energy } u + \text{external work}$$

and since the external work varies with the path, Q likewise depends on the path.

It is most unfortunate that the name "heat content" is often given to the potential function I. This name gives rise to endless confusion in the minds of students and possibly in the minds of professors also. The association of Q and I in the case of saturated steam is probably responsible for the troublesome situation. Professor Goldman says that the heat content (that is, the value of I) of steam at a pressure of 100 lb. is fixed and definite, irrespective of how the steam was produced. This statement is strictly true; but it is *not* true of the heat Q absorbed in the change from water at 32 deg. to steam at 100 lb. The accompanying figure illustrates this point.

If, as usual, the water is heated and vaporized at constant pressure the area between QAB and the N-axis represents the heat absorbed and also the change of I from water at 32 deg. to saturated steam in the state B; or, neglecting the small value of I at point O, the area under OAB represents the value of I (the heat control) at state B. But the same state B may be attained by some other path as $OCDEB$ or $OFGB$. In the first of these the water is boiled at a higher pressure, then superheated as indicated by DE and then expanded adiabatically, as shown by EB. The heat absorbed in this case is represented by the area under $OCDE$. Or, if the water is vaporized at a lower pressure along FG, and the mixture in the state G is compressed adiabatically from G to B, the heat absorbed is represented by the area under OFG. Thus the Q absorbed between O and B may have different values depending on the character of the process, but the I at point B is fixed and definite and is represented by one area, that under OAB.

The object of the preceding discussion is to emphasize the point that there is no necessary connection between the so-called heat content of a system and the heat Q absorbed in some change of state of the system. In just one case, that in which constant pressure is maintained in the system, the change of I gives the heat absorbed; in all other cases the two magnitudes have different values.

Professor Goldman says that H denotes the heat energy. It may be assumed that his H stands for either Q or I. In the former case his definition of entropy, namely $dN = dQ/T$, agrees with the authorities from Clausius down. If such is the case, the alleged functional relation $N = f(H,E)$, which translated into the customary notation becomes $N = f(Q,T)$, simply does not exist. Since Q depends upon the path it is not a function of the variables that define the state, and to say that any of these variables is a function of Q is nonsense. Hence, with the proper definition of entropy, the mathematical discussion under section (a) breaks down completely.

But from the discussion (b) it seems probable that Professor Goldman has confused Q and I, and has used dI instead of dQ in his definition. In this event the mathematical discussion is correct, and the entropy that "is an error" is a new, special brand of entropy defined by the equation $dN = dI/T$. Thus Professor Goldman demonstrates that his particular entropy, not the time-honored entropy of Clausius and Thomson, does not behave in accordance with the established rules. In other words, he knocks down a man of straw that he has himself constructed.

The Hardness Testing of Metals

TO THE EDITOR:

The writer has just read, with considerable interest, in the July issue of MECHANICAL ENGINEERING the report of a committee of the Engineering Division of the National Research Council on The Hardness Testing of Metals, and having spent some time on the hardness testing of steel, both in the annealed and hardened state, feels that comment will not be out of order. To all of those who are connected in any way with the acceptance of raw material upon its entering the shop or of the same material after different operations throughout manufacturing there comes a time (particularly in the fabrication of high-carbon or alloy, steel products which are to be more or less highly stressed or abraded in operation) when the acceptance or rejection of those parts is absolutely dependent upon some method of hardness testing, and it is at this time that the inadequacy of our present methods of determining hardness is most forcefully brought home, particularly if the material is near the dividing line between "hard" and "soft." That, it is almost universally conceded, is a fairly well-established fact.

The suggestion of Mr. Hultgren of the use of etched balls to bring out more clearly the indentations made by the Brinell testing machine, may at first seem to be a decided step for the better, and undoubtedly on some grades of steel this will give satisfactory results, but on extremely hard, tough alloy steels the etched ball has little, if any, effect in making readings easier unless etched very

deep. The writer has tried this where the indentation of a polished ball was vague, and although the imprint of the etched ball was plain at the bottom of the crater it grew less distinct at the edges, in many cases being imperceptible. If the ball is etched very deeply, say three or five minutes in concentrated HNO_3, then the print is more clear, but the value of the test has been lost if accuracy is to be adhered to. In connection with this the writer has tried several methods, some of which work satisfactorily, namely etching the specimens, coloring the ball with various substances such as carbon or prussian blue, or so polishing the specimen that very fine streaks are left on the surface, which, when struck by light rays, will stand out in relief. It may be argued by some that etching the specimens will tend to break down the surface; however, of the two evils it is better to break down the surface of the sample than that of the ball, for the depth of indentation is reached when an equilibrium is established between the pressure exerted by the ball and the resistance to penetration offered by the metal, and this

Micrograph Showing Effect of Bluing the Ball in Hardness Testing

is reached at the end and not at the beginning of the travel of the ball into the metal.

In using some coloring substance prussian blue seems most satisfactory, for as the ball penetrates the sample the fluid is squeezed to the boundary and in no way interferes with the test. The accompanying micrograph illustrates this. It is not offered as an ideal sample of indentation, but to show the effect of bluing the ball. In this connection it is of interest to note that all of the bluing has not been squeezed to the boundary, which would indicate that the ball was not absolutely spherical. On investigation this was found to be true, for the ball (10 mm. in diameter) was measured before loading and while under a load of 3000 kg. it was found to be some 0.0004 in. larger on an equator equidistant from the points of contact with the specimen and plunger. This explains the fact that the bluing was not all forced out, for while under pressure the ball fits the indentation, but as soon as the load is released the ball assumes its original form and no longer fits the crater except at a small area at the bottom, allowing the bluing to creep back. This accounts for the possible error of reading width rather than depth of indentation in determining hardness values and speaks decidedly in favor of the depth method.

Referring to the sections of the report dealing with the Brinell meter and Morin hardness-testing apparatus, the only advantage these instruments have is their portability, which of course is the reason for their development. There is certainly more chance for error, for, first a standard is determined in the regular way and then a sample tested and compared with that standard. To say that for very hard steels the Brinell method is more or less guesswork would be making a rather broad statement, but it is an established fact that a hardened ball can be forced into a flat surface, even though the surface is harder than the ball; furthermore, there is no present absolute method of determining hardness or softness, it being a matter of comparison, and there can easily be variation enough in ball hardness, even though the balls be specially selected, to give variant results and incorrect readings.

R. H. Coolidge.

Chicago, Ill.

What of the Young Engineer?

To the Editor:

Prominent men in the engineering profession are today turning their attention to the various industrial problems now confronting the nation. An investigating committee, headed by Mr. J. Parke Channing and L. W. Wallace, has recently completed an industrial survey that was nation-wide. The gentlemen conducting this survey have gone over the ground in a thorough and painstaking manner and have gotten results that are admittedly accurate. Their report, among other things, places the responsiblity for the elimination of business waste, depression, and general debility upon management.

Admitting that lack of knowledge on the part of management is the prime cause of wasteful, inefficient running and even failure in business, does it not show that there is a general lack of training in this most important phase of industrial activity? It would seem that the heads of these concerns, the general executive staff, have not had the proper grounding in the rudiments and fundamentals of executive knowledge. The remedy is obvious—select the right men for the governing heads of the particular industry in question and let them renovate and instill new life and energy into it. But men of this type are not easily procurable, nor can they be trained at a moments' notice. The few national geniuses in this line need not be reckoned with in this discussion. Where are men who possess the necessary qualities for such a position to be found?

Our technical colleges and our universities are turning out just such men year after year; turning out men who have been trained to think for themselves along orderly lines. The curriculum of these schools endeavors to give to all their students as broad an industrial education as can possibly be combined with the necessary purely technical knowledge that they must assimilate. It would seem, then, that the technical graduate is not only the logical man to train for such a position, but also practically the only candidate with a full complement of the necessary mental equipment.

The cause of the waste has been found, a preventive measure for the future is at hand, but is it being used? Not if we are to take into account the situation as it stands today. Vast numbers of recent technical graduates are today without positions, without a chance to get one. These men have put in four or five years, as the case may be, of the hardest grind. They have, for the most part, made great sacrifices of time and money; they have worked, scrimped and saved for their education because of their determination to fit themselves for a career. Now that the constructive work is finished and ready for use, they are worth—if the present attitude of the older engineers and business men is to be considered—*exactly nothing*.

Why, then, do prominent engineers make exhaustive investigations and reports upon business diseases and yet have no thought for remedying a condition which will further aggravate the situation? Machinery improvements may speed up production, new cost systems and routing methods may cut costs and time of handling merchandise, but in the last analysis brains and human energy are the motive power behind them all. Why try to doctor the disease without removing one of the chief causes? What the country's business needs is more trained men and plenty of them.

The potential creative power, the potential wealth of knowledge and intensive training that is stored up in the brains of these young men, if allowed to go to waste through lack of opportunity, will be a staggering loss to the engineering field. Engineers view, with grave concern and some alarm, the diminishing of our oil reserves, our forests and our coal mines; but they allow this waste of human energy and ability of the highest order to go unchecked. This enormous waste, of graver consequence than all the others put together, is still allowed to go on because engineers do not perceive, or will not perceive, the far-reaching ill effects of such a policy.

Does the present condition of affairs indicate that there is no further need for the technical graduate, at least for the next year

Powdered Coal as a Boiler Fuel

While powdered coal has been burned under boilers for over twenty years, the installations have consisted mainly of small units designed for burning coal on grates which were changed over, with only minor alterations, to burn this new form of fuel. These rebuilt installations, however, were not without their value, since they demonstrated very clearly that for best results with this type of fuel a design of furnace was required which differed radically from that used with stoker- or hand-fired boilers.

Edwin B. Rickets

The first large central station designed for the exclusive use of powdered coal is the Lakeside plant of the Milwaukee Electric Railway and light Company and great credit is due Mr. John Anderson, chief engineer of the company, for his pioneer work in this field and his courage in making such a radical departure in power-station design.

The tests on No. 8 boiler at the Lakeside plant, made by Henry Kreisinger and reported elsewhere in this issue, have clearly demonstrated that efficiencies are possible with this fuel fully equal to those obtained in the best oil-burning plants and 2 or 3 per cent better than has been done with the best stoker installations. The difference in best test efficiencies between powdered coal and stokers would not be sufficient to overcome the handicap of extra preparation costs with powdered coal, but, due to its greater ease of regulation, it is much easier to maintain with powdered coal—as with oil—efficiencies in regular operation closely approaching those obtained on tests than with stokers. The difference in efficiency in regular operation would probably be in the neighborhood of 6 or 7 per cent in favor of powdered coal.

Of the problems which confronted the would-be user of powdered coal some years ago, many are approaching solution. The efficiencies obtained at Lakeside leave little to be desired, and while as high capacities have not been realized as with stokers, it has been demonstrated that capacity is largely a matter of furnace volume and draft. The problem of driers has for most cases been eliminated, as evidenced by the fact that the River Rouge plant of the Ford Motor Company is operating satisfactorily on coal having 15 per cent moisture without driers. Considerable progress has been made in reducing the fineness of grinding, and while we may never reach our ultimate aim of burning crushed coal in suspension, the indications are that in the future we will burn much coarser coal than is thought possible now. On the matter of grinding costs there is much to be desired in the data available, figures from various plants running all the way from 30 cents to $3 per ton. It is hoped that costs on some of the modern grinding plants which have been installed in the last year or two will be published as soon as the plants have been operating long enough to make the data reliable. While the fact that about 90 per cent of the ash in the coal passes out the stack may not be a problem in some industrial communities, it is a very vital one in our large cities. Experiments are now being made to catch this material, but so far no satisfactory means has been perfected.

That powdered coal as a boiler fuel is here and here to stay, few will question; that it will eliminate other means of burning coal is hardly possible. There is undoubtedly a field where this fuel will prove the best, as there are others where stokers, oil or gas will reign supreme. When only very low-grade coal which is burned with great difficulty on stokers is available and where coal is very high in price, powdered coal would seem to have a decided advantage over stokers. Where good stoker coal is available at a low price, the advantage is with the stokers. With eastern seaboard conditions—a good grade of coal available at a medium price—the best method of burning fuel becomes a matter for very close calculation. The extent of the place which powdered coal will occupy in the future none can foresee, but the problem of the engineer in considering this fuel in the same as that with all other types of fuel, namely, the careful balancing of efficiency against the cost of obtaining that efficiency. Edwin B. Ricketts.

Engineers Conducting Pre-College Education

It is to be hoped that no engineer, whether specially interested in the subject of education or not, will fail to read the article in the *Atlantic Monthly* for July entitled Mastering the Arts of Life. The article is an account of the efforts of Col. E. A. Deeds, Mr. C. F. Kettering and Mr. Arthur E. Morgan to break away from the conventional methods of education for the young, whether as a preparation for "life" or for college, and of the results so far achieved.

Colonel Deeds needs no introduction to our readers, and Mr. Kettering also is a man of achievement in the automotive field, while Mr. Morgan is the engineer who has directed the colossal work of flood prevention in the Miami Valley in Ohio.

Starting with the desire only to provide for the primary education of their own children in a way which they believed would be a much better preparation for real life in a real world, than is afforded by the standard pedagogic methods of the primary, grammar and high schools of the country, this school has grown into what appears to be an institution and it seems to answer thoroughly and satisfactorily many of the problems of those who, having children to train for a life of honorable usefulness, feel that the standard school methods do not meet the requirements of the present time, and are at a loss as to what to do about it.

All the methods followed in this school seem to be as different from the usual pre-college educational methods as could well be yet its graduates are really educated in the best sense of the word and if they wish are admitted upon certificate to colleges.

No condensation of the short article in the *Atlantic* can do it justice; but, suffice it to say that all the usual tests by means of examinations are eliminated and new standards are set up—such standards as the pupils will be judged by in the actual world in which their lives are to be spent.

Referring to the earlier period, before the elaboration of the modern school system, when the farm boy "had but three months of schooling in the year; which left nine months for him to get an education," it is declared that we have copied our school methods largely from the Germans or the classic English schools and have crowded out the American sort of education. "To make Americans you must inculcate and strengthen American traits. That, our schools are not doing. Initiative is a prime American trait, but our schools teach conformity. We are an ambitious people, but

our schools tend to delegate athletics to specialists. The American is many-sided, but our educational system aggrandizes only one side of the mastery of living. Business shrewdness is another distinctive American trait, but our education does not give us business power. We believe in democracy and self-government, and our schools are autocracies. We are a religious people, and our schools are unreligious, repressing the spiritual element in education through fear of offending sectarian prejudices."

Aside from the interest this article has for every intelligent person interested in education, it possesses special interest for engineers as an account of how competent engineers have applied the methods of the engineer to educational problems: i.e., sat down and carefully considered what training a young person should have to best qualify him, not solely for making money, or for "being successful" in the ordinarily accepted sense of that term, but for that real success which comes from not alone the ability to make money, but the ability to render service and to live a full and well-rounded life of usefulness and of satisfactory achievement as an individual and as a citizen member of coöperative society. The school has been designed to accomplish that object and in its design the traditional methods of pedagogy have been almost entirely discarded and the result is most excellent as regards the physical well-being and the mental and moral development of its very fortunate pupils.

This school has also a very interesting relation to the paper by Mr. H. E. Miles, which appeared in the August number of MECHANICAL ENGINEERING, and which has attracted a great deal of attention as a masterly presentation of points in which the standard educational methods fail in their adaptation to present-day conditions, and offers suggestions for improvements such as would scarcely occur to anyone not acquainted by experience with what most of the worlds' producers really need by way of education to enable them to lead the most useful and successful lives.

The Airship Disaster

WHEN the Quebec Bridge failed the general feeling in the engineering profession was that the disaster was due not to lack of competence on the part of the designers and erectors, but rather to a lack of knowledge of thebehavior of structures of such size.

In the early days of ore transportation on the Great Lakes there were several failures of steel ore boats which simply broke in the middle and plunged to the bottom like a stone. This again, was ultimately found to be due to peculiar, and, until then, unknown stresses to which vessels of such great length were subjected in certain parts of the Great Lakes. Once this became known, a comparatively simple change of design was made and ore transportation became safe.

There is good reason to believe that the fundamental cause of the airship disaster lies also in lack of knowledge of vital elements underlying the design of large airships. It is, at times, difficult to realize how slight our knowledge of airship engineering really is. We are dealing with structures 600 to 700 ft. long, weighing in the air next to nothing. At both ends of these immensely long structures we have operable planes (rudders and elevators) of very considerable size, presenting resistance to the air equal to a pressure estimable in tons, which, with a leverage of some 300 ft., must impose tremendous stresses amidships. What these stresses are we do not know, nor have we either experimental or mathematical bases for computation. This is particularly so, as we do not even know to what extent the theoretically rigid dirigible is capable of flexure.

Such a situation would have been bad enough if we were dealing with materials with whose behavior we are familiar, but we are not. The main resistance parts of the dirigible are constructed of the so-called "duralumin"—an alloy of aluminum and copper, or aluminum and zinc, or all three of them. Duralumin is, however, a new alloy, practically a "war baby," and we have only scant knowledge as to its behavior and next to no knowledge as to its ability to withstand repeated stresses—something of particularly great importance in a structure that is vibrating like a string all the time. In airship design we have therefore to meet unknown stresses with a material of unknown qualities, which would be bad enough in itself but is stupendously aggravated by another circumstance, and that is the very low factor of safety employed in airship construction.

In a bridge, an ore boat, an automobile, generous factors of safety are used wherever there is doubt as to the stresses to which a member is likely to be submitted, because there is no vital gain outside of the cost consideration, which should be secondary in using excessively light members. But this is not so in an airship. If the latter is designed to fly across the Atlantic it must carry a certain weight of gasoline, oil and useful load, and every pound of these supplies reduces by a pound the weight of the metal that can be put into the structure, and hence the factor of safety, with the result that members one sixteenth to one eighth of an inch in thickness are by no means uncommon in dirigible construction; and members of such slender dimensions in duralumin, under the tremendous stresses they are called upon to withstand, no longer possess a factor of safety but rather a factor of daring.

The airship has a certain military value, and in a war structure the lack of sufficient safety may not be considered a vital objection to its employment. For peace purposes the airship can probably be also made sufficiently safe after enough time and money have been spent in experimental work. It may be of interest to note that out of about fifty big dirigibles built so far at least one-third have met a violent end.

It was evidently from such a point of view as that, that the National Advisory Committee for Aeronautics passed a resolution recommending the government to continue its work on dirigibles, and to purchase for this purpose a discarded German Zepplin. A more thorough investigation of the properties of duralumin, its heat treatment, "ageing," behavior under alternating stresses etc., might also be of interest, and not for the design of dirigibles airships only.

The Lakeside Plant Pulverized-Fuel Tests

Much interest was aroused at the A.S.M.E. Spring Meeting in Chicago by the high boiler efficiencies reported by Mr. Henry Kreisinger as having been obtained in tests at the Lakeside Plant of the Milwaukee Electric Railway and Light Company, where pulverized coal is exclusively used as fuel. These tests and an additional one, which are commented on editorially in this issue, have been recalculated with the B.t.u. determinations made by the Bureau of Mines and are printed below, together with further particulars regarding the plant which have been kindly supplied by Mr. Kreisinger for publication.

SUMMARY OF RESULTS OF FIVE BOILER TESTS WITH PULVERIZED ILLINOIS COAL. TESTS MADE ON BOILER NO. 8, LAKESIDE STATION OF THE MILWAUKEE ELECTRIC RAILWAY AND LIGHT CO.

Test No.	1	2	3	4	5
Duration, hr.	42.33	23.97	19.92	24.20	24.17

PRINCIPAL DIMENSIONS OF BOILER AND ECONOMIZER AT THE LAKESIDE PLANT

Boiler.—Edgemoor four-pass with 563 4-in. tubes 20 ft. long (15 high by 37 and 38 wide), and 5 steam drums. Total heating surface, 13,060 sq. ft.

Water Screen.—22 4-in. tubes each with an average exposed length of 13¾ ft.; total heating surface of exposed part of tubes, 320 sq. ft. Total heating surface of boiler and water screen, 13,380 sq. ft.

Superheater.—Foster.

Economizer.—Sturtevant, with 528 4½-in. O. D. cast-iron tubes 12 ft. long (12 wide by 44 long); provided with a steam-turbine-driven induced-draft fan.

Furnace.—Average width, 22 ft.; average length, 14 ft.; height under tubes, 25 ft., height under arch, 22 ft.

Burners.—6 flat Lopulco burners used; air supplied to feeders and burners under pressure of 12 in. water.

Peter Cooper Hewitt Dies

Peter Cooper Hewitt, one of America's well-known inventors and engineers, died in Paris on August 25, 1921, from pneumonia following an operation. Mr. Hewitt was born in New York on March 5, 1861, and was educated at Stevens Institute and at Columbia University, being graduated as a mechanical and electrical engineer. He received the honorary degree of Sc.D. from the latter institution in 1903 and from Rutgers College in 1916.

In addition to his inventions Mr. Hewitt took an active interest in a number of industrial corporations and in the work of many technical and social clubs to which he belonged. He was a trustee of Cooper Union, founded by his grandfather, and in 1915 was appointed a member of the United States Naval Consulting Board.

His chief inventions were the mercury-vapor electric lamp, the static converter or rectifier used to convert alternating currents into direct currents, the electrical interrupter, and the wireless receiver. The telephone relay and electric wave amplifier, as well as apparatus for use in connection with the wireless telephone and telegraph, were also devised by him.

Major L. A. Fischer, Scientist, Dead

Major L. A. Fischer, chief of the Division of Weights and Measures of the U. S. Bureau of Standards, one of the most prominent scientists of Washington and the foremost leader of the movement to promote a uniform system of weights and measures, died on July 25 at his home in Washington, D. C.

L. A. Fischer

Major Fischer was born in Washington, D. C., on January 4, 1864. His activities in the field of weights and measures began early in life when he joined the staff of the old weights and measures office of the Coast and Geodetic Survey. After many years of active service in this office he took a prominent part in the establishment of its successor, the United States Bureau of Standards, in 1901, in which institution he was made chief of the Division of Weights and Measures. In addition his scientific attainments won him a world-wide reputation as one of the leading American metrologists.

For a number of years Major Fischer was regularly appointed by the President to serve on the Assay Commission. In the course of this work he personally tested the standards employed at the mint against carefully calibrated weights which were especially tested in his own laboratories at the Bureau. In 1915 he served as a member of the jury of awards at the Panama-Pacific Exposition. During the war he was commissioned major in the Ordnance Department of the United States Army and placed in immediate charge of the important section of gage design.

Major Fischer was a graduate of George Washington University. He was a member of the Washington Academy of Sciences, the American Physical Society, the Physical Society of France, a fellow of the American Association for the Advancement of Science, past-president of the Philosophical Society of Washington, secretary, since its organization, of the National Conference on Weights and Measures. He was also a member of the Cosmos Club of Washington.

Since his early youth he had been prominently identified with athletics in the District of Columbia. He was a leading oarsman in the Potomac and Analostan Boat Clubs and later became a member of the tennis teams of the Old Bachelor Tennis Club, the Dumbarton Club and the Columbia Country Club.

Major Fischer became a member of The American Society of Mechanical Engineers in 1918 and took most active interest in its work, particularly in the field of screw threads and limit gages. He was but recently elected chairman of the Washington Section of the Society.

Kenneth Rushton Dies

Kenneth Rushton, vice-president in charge of engineering, The Baldwin Locomotive Works, died September 2, 1921, at the age of sixty years. Mr. Rushton was born in Philadelphia, Pa., and was educated in the city schools and Episcopal Academy. He served an apprenticeship as machinist under Hugo Bilgram, of Philadelphia, and afterward entered the employ of The Baldwin Locomotive Works in April 1881.

continued uninterruptedly until the time of his death; first as a draftsman, and later as designer, chief mechanical engineer, and finally as vice-president. He was the inventor of many appliances used in the construction of locomotives, and was closely associated with S. M. Vauclain in the development of the four-cylinder compound that bears the name of the latter. While Mr. Rushton did not travel extensively in the prosecution of his business, he represented Baldwin's abroad on some important missions. In 1913 he was sent to Chile, visiting various points of railroad interest on the west coast of South America, and in 1918 went to France in connection with the design of railway transport for artillery.

Kenneth Rushton

Mr. Rushton became a member of The American Society of Mechanical Engineers in 1918, and served actually on the Sub-Committee of its Boiler Code Committee on Boilers and Locomotives. He was also a member of the American Society for Testing Materials.

Research Laboratory

F. Paul Anderson, dean of the College of Engineering, University of Kentucky, has been appointed director of the Research Laboratory of the Committee on Research of the American Society of Heating and Ventilating Engineers, to succeed the late John R. Allen. L. A. Scipio, who has been acting director since Dr. Allen's death in October 1920, has been recalled to his position as dean of Robert College, Constantinople.

Following his graduation from Purdue University in 1890, Dean Anderson spent some months as designer of special machinery with the Studebaker Company, at South Bend, after which he devoted a year to experimental engineering at Purdue University. For 30 years he has served respectively as professor of mechanical engineering, director of experimental laboratories, and dean of the College of Engineering of the University of Kentucky, formerly the State College of Kentucky. He was for 25 years engineer of tests for the Southern Railway Company, and at the same time carried on a consulting engineering and architectural business.

Dean Anderson has long been noted as an investigator, having been the first engineer in this country to experiment with Roentgen rays. At the University of Kentucky he specialized in steam and locomotive engineering and materially developed the laboratory.

Dean Anderson is a member of the Society for the Promotion of Engineering Education, The American Society of Mechanical Engineers, and the American Society of Heating and Ventilating Engineers, as well as of various other social and technical societies and clubs.

News of The Federated American Engineering Societies

Report of Patents Committee on Stanley Bill

The Patents Committee of American Engineering Council, of which Edwin J. Prindle is chairman, has recently issued a report on the Stanley Compulsory Working and License Patent Bill, S. 1838, which proposes to require that all alien-owned American patents shall be worked in this country within two years after granting. Some of the arguments for and against this bill were set forth in the July issue of Mechanical Engineering, page 494. The report of the American Engineering Council Committee states that the committee "believes that the changes proposed in the Stanley Bill would be much more harmful than beneficial and would probably ultimately be disastrous, and therefore recommends that the Stanley Bill be vigorously opposed." Some of the reasons which the committee report gives for this conclusion are, in part:

There is grave danger that if compulsory working, under penalty of having licenses granted to others, is introduced into our law, as applied to patents issued to foreigners, it will be extended to apply to all American patents. It would be a catastrophe to require that all American patents be worked within any limited period under penalty of losing the monopoly by having licenses granted thereunder by the Government.

Such a provision would strongly tend to impair the value of patents and would, to that extent, discourage or fail to induce the production of inventions. Such inventions as were produced would be largely those which could be monopolized by being kept secret.

The great prevalence of the inventive faculty in America is due to the stimulus of the promise of a monopoly for seventeen years which our patent law offers.

If the individual inventor, or even the corporation, were faced not only with the often back-breaking burden of expense in developing an invention, but also with the necessity of putting that invention on the market within two years, or even a much longer period, they would often not attempt what is now successfully put through.

An invention is often of no commercial value because it is ahead of its time, and the patent must wait until the art has grown up to it before it can be profitably worked. Under these circumstances, the expense of commercially working it would be entirely thrown away.

The making of a successful invention today is not usually a question of a single patent, but in the course of the development of the invention, to a thoroughly commercial form, a group of patents has usually been taken out, either upon the article itself or upon instrumentalities and processes for its manufacture, and the patents of others are often found to be infringed and need to be purchased. In such a case the patents would usually have been taken out successively over a number of years, and thus each patent of the series would, under the Stanley Bill, have to be worked within two years while the working of that patent alone was of no commercial value and the success of the enterprise as a whole was still in doubt and might never be achieved.

The requirements of the Stanley Bill would obviously discriminate strongly in favor of the wealthy, and against the poor, inventor. That would not only discourage the production of inventions, but harm industry in general, for there are many successful businesses in this country which are based upon the inventions of their owners made when they were without capital.

No country which has a compulsory working clause in its patent law produces anywhere near the number of inventions per capita or in importance which are produced in this country. The very small and seemingly insignificant inventions produced under our patent system are often of great value to the public, although usually not to their inventors, because they lead step by step to a point of view from which some one sees an opportunity to make a really important invention that would not otherwise have been produced.

Registration of Engineers

A meeting of the American Engineering Council's Committee on Licensing and Registration of Engineers was held in the rooms of the Western Society of Engineers, Chicago, on September 19, for the purpose of giving a hearing on the Uniform Registration Law recommended by Engineering Council in November 1920. Engineers in general had previously been invited to prepare briefs and submit them to the Committee, either by mail before the meeting or in person at the hearing. The proposed changes were discussed in detail, as were also the recommendations on whether or not the Federation should use its influence to have the uniform law introduced in legislation in states where laws are not already in force. The findings of this hearing will be given in a later number of Mechanical Engineering.

International Cost Conference

Mr. L. W. Wallace, secretary of the American Engineering Council conducted the third session of the International Cost Conference held under the auspices of the National Association of Cost Accountants, at Cleveland, September 14–16. Arrangements for this session were the result of the work on the part of the Committee on the Elimination of Waste in Industry. Three members of the Committee in addition to Mr. Wallace presented papers, namely, John H. Williams, William R. Basset, and Robert B. Wolf.

Chemists Discuss Developments in Scientific Research

American Chemical Society and Society of Chemical Industry Hold Four-Day International Meeting in New York City

THE sixty-second meeting of the American Chemical Society, held in New York September 7–10, was attended by over 6000 chemists representing that society, the American sections of the Society of Chemical Industry and the Société de Chimie Industrielle, the British Society of Chemical Industry and its Canadian sections, the American Electrochemical Society, and the American Institute of Chemical Engineers. The Chemists' Club was the social headquarters for this international gathering and the business sessions were held at Columbia University and the College of the City of New York.

Over a score of papers were presented. Arthur D. Little, chemical engineer and technologist of Boston, Mass., spoke on Energy: Its Source and Future Possibilities, discussing some of the new sources of energy. The radiant energy of the sun, he stated, "is only three small calories per minute per square centimeter of the earth's surface, but it has been calculated that a surface of only 10,000 square kilometers (3860 square miles) receives in a year, assuming only six hours as the effective day, a quantity of heat that corresponds to that produced by the burning of 3,650,000,000 tons of coal. The Desert of Sahara receives daily solar energy equivalent to that of 6,000,000,000 tons of coal. The world awaits the genius who will convert radiant energy into electric current." The energy of the earth's rotation and tidal energy were also discussed by Dr. Little. The former has thus far been utilized only through the gyroscope. Concerning the latter he believed that intermittent flow, varying head and other special conditions involved are likely to hold the development of tidal power within closely restricted limits. Kinetic energy possessed by radium and also by ordinary matter as the constitutional energy of atoms, he said, are further power sources of great interest to chemists.

Wilder D. Bancroft, professor of physical chemistry at Cornell University, presented a paper on Catalysis, the New Economic Factor. He was of the opinion that the most promising way in which chemists could develop methods of increasing production and decreasing costs lies in a better utilization of the possibilities of catalytic action. He predicted the use of a catalytic agent in speeding up the reaction which gives rise to cold light and in causing rain clouds to precipitate into arid regions and was sure that the availability of the energy in sunlight and in atoms involves catalysis. Reid of the Johns Hopkins University had apparently furnished the missing experimental proof. He passed a mixture of the vapors of ethyl aclohol and acetic acid for twenty-four hours over silica gel as catalytic agent, and during the whole of that time he obtained about 10 per cent more of ethyl acetate than corresponds to the theoretical equilibrium. The displacement of equilibrium by a catalytic agent he thinks may be an avenue to extraordinary possibilities in making organic compounds. A displacement of 10 per cent in the right direction in the synthesis of ammonia, for instance, would be revolutionary.

An interesting paper on a Chemically Controlled Automobile was presented by George G. Brown, Jr., an instructor in the chemical engineering department of the University of Michigan. Mr. Brown had been working for some time on the development of a carburetor which automatically delivers the leanest and most efficient mixture possible with every temperature condition when the car is running under light load, and automatically enriches the mixture according to decreased speed or increased load when the car encounters increased resistance, so that acceleration, hill climbing and flexibility are not sacrificed when obtaining maximum economy. This carburetor, he stated, produces a mileage of from 30 to 45 miles a gallon, depending on the car and the roads.

Dr. Sidney Born, of Muskogee, Okla., in speaking of saving petroleum at the wells, said that different processes were used at different fields. Among these processes are the steaming plant, the Cottrell or electrical, and the super-centrifuge. The latter method, by which petroleum is recovered from the emulsion of salt water, oil and various impurities found in many oil wells, makes possible an economy of millions of dollars.

Following a discussion of the German chemical industry by Francis P. Garvan, president of the Chemical Foundation, Inc., the meeting adopted a resolution to Congress, urging, among other things, the necessity of including in the permanent tariff bill a selective embargo for a limited period against importation of synthetic organic chemicals. Sir William Pope, professor of chemistry at Cambridge Univerity, touched on the same subject when in the course of his address on Mustard Gas he stated that every dollar which was spent in this country on German dyes during the war, and every pound spent in England for German dyes, was a contribution to the German war chest.

Dr. Leo H. Baekeland, honorary professor of chemical engineering in Columbia University, in his address on The Engineer: Human and Superior Director of Power, said that there are enormous possibilities in the range of photochemistry. "Our vast coal beds and our petroleum wells and our natural gas," he said, "are simply the results of light energy stored up from the plant or animal life of former geological periods, yet here is a field where the scientist or engineer has accomplished next to nothing."

Some of the other subjects discussed were Organization of Industrial Research in Canada, by Prof. R. F. Ruttan of the Canadian Chemical Society; Theories on the Development of Research, by Dr. Willis R. Whitney, head of the research department of the General Electric Company; Problem of Diffusion and Its Bearing on Civilization, by Prof. Ernst Cohen, professor of chemistry at the University of Utrecht; and Research Applied to the World's Work, by Dr. C. E. K. Mees, head of the research department of the Eastman Kodak Company.

The last day of the meeting was devoted to excursions to various industrial plants in New York, including those of the National Biscuit Company, the American Tobacco Company, Standard Oil Companies of New York and New Jersey, Manhattan Rubber Company, Passaic Print and Dye Works, and the Seaboard By-Product Coke Company.

It was decided to hold the 1922 convention in April at Birmingham, Ala., and the fall meeting at Pittsburgh in September.

Book Notes

THE A.B.C. OF IRON AND STEEL. Edited by A. O. Backert. Penton Publishing Co., Cleveland, 1921. Cloth, 8 × 11 in., 408 pp., illus., $5.

This is a simple, concise, yet comprehensive account of the primary processes involved in the conversion of iron ore into finished products, intended for general readers who wish a knowledge of these processes, and for technical readers wishing general information on phases of the industry outside their own experience. The book is elaborately illustrated.

BROACHING PRACTICE. By E. K. Hammond. The Industrial Press, New York, 1921. Paper, 6 × 9 in., 122 pp., illus., $1.

For many years broaching has been used for cutting keyways and machining holes to a variety of shapes, but the method attracted little attention until comparatively recently. With the rise of the automibile industry, broaching machines came into common use and now are extensively used in building many products. This book is a concise review of modern practice, explaining the machines, the design of broaches and the application of the process to many classes of work.

CONCRETE DESIGNERS' MANUAL; TABLES AND DIAGRAMS FOR THE DESIGN OF REINFORCED CONCRETE STRUCTURES. By G. A. Hool and C. S. Whitney. McGraw-Hill Book Co., Inc., New York, 1921. Cloth, 276 pp., $4.

These tables and diagrams facilitate the rapid design of structures in accordance with the Joint Committee recommendations, the American Concrete Institute recommendations, the New York Building Code requirements and the Chicago Building Code requirements. Some of them are general enough also to be used when the requirements are different from those mentioned. The collection is the result of the authors' practical experience.

CONTROL OF CORROSION IN IRON AND STEEL

(Continued from page 662)

are decidedly favorable, confirming the theory stated in the first part of this paper which has now been generally accepted, that corrosion is due primarily to the dissolved oxygen in water. The water is sprayed into a chamber under about 28in. vacuum, by which 90 per cent of the gases are removed and corrosion thereby reduced to one-quarter or one-fifth of the original amount.

It is much easier to study the various factors which influence corrosion in a closed system where all conditions are under better control. Early experiments in 1907 indicated the great influence of dissolved oxygen in water on corrosion. Careful laboratory experiments by Dr. W. H. Walker and the author, covering a period of several years have demonstrated that the amount of corrosion is almost directly proportional to the oxygen in solution, and also varies directly as the temperature. Hot-water heating systems in buildings invariably show no corrosion to speak of after 35 or 40 years' use, whereas frequently hot-water supply systems operating at the same average temperature with the same water last less than half of that time, the only difference being that the former carry no oxygen, while the water on entering the latter is usually saturated with oxygen.

Protection Against Internal Corrosion

From the foregoing it will be seen that in addition to the use of protective coatings, under some conditions it is more economical to prevent internal corrosion by removing the dissolved oxygen from water. In fact, experience has shown that with hot water the latter method is much more effective and economical in the long run.

In practice the removal of oxygen from water has been accomplished in two ways:

1 By mechanical deaeration, for which there are two or three designs of apparatus in use giving satisfactory results.

2 By chemical combination with some material such as scrap sheet iron.

Both methods may be combined by using mechanical deaeration to remove the larger portion of oxygen and the chemical treatment for residual oxygen. Considerable has been written on this subject during the last few years with reference to the control of corrosion in hot-water supply systems, to which those interested may refer.[1] The most economical plan for any particular case depends very largely on local conditions.

The control of corrosion in condensers, especially where salt water is used, may be accomplished by deaeration, and there are probably many other cases where this principle can be applied economically to engineering practice.

For the internal protection of water mains by coating the metal, under most conditions a dip in a bath of well-refined asphalt or coal tar will be sufficient. Again the importance of thorough cleaning and the removal of all scale from the steel, so far as practicable, should be emphasized.

Concrete has been used to a limited extent for the protection of the inside of pipes from 1 in. to 11 ft. in diameter. Small service pipes have been used for thirty years in New England with an internal coating of $^1/_8$ in. of neat cement applied by means of some simple appliances designed for the purpose. This coating has also shown great durability as a lining for steel or wrought-iron pipe carrying mine water, and when properly applied to the clean surface and about $^3/_4$ in. in thickness, is difficult to break off or injure unless there is much variation in temperature.

The 11-ft.-diameter rivited-steel pipe sections of the Catskill Aqueduct were lined with 2 in. of portland-cement grout. The plates of which this pipe was made were first pickled free from scale and given a coat of whitewash to prevent rusting. The outside of the pipe was protected by a coat of 1:3:5 concrete mixture 4 in. thick at the top. The reports from this line, which was put into service in 1915, indicate that this coating has been satisfactory so far as can be ascertained at present. It is interesting to find that the friction losses in the cement-lined Catskill conduits are less than in the unlined pipe under these conditions, notwithstanding the reduction in diameter of the lined pipe.

What has been written above necessarily deals in general principles. The details of the application of these principles to practice in various cases will of course require variation to suit local conditions. Considering the great economical importance of conservation of material in our day, it would seem that the boundaries of engineering practice should be broadened out a little so as to include more of anti-corrosion engineering.

[1] Paper by J. R. McDermet on the Separation of Dissolved Gases from Water and discussion. A.S.M.E. meeting, St. Louis, May 1920. Papers by F. N Speller, W. H. Walker and R. G. Knowland, Trans. A.S.H.&V. Engrs., 1918 and 1920.

What of the Young Engineer?

(Continued from page 691)

or so? Have the bigger men in our profession deliberated upon the question and decided that no help need be given to the new men to find themselves? Again, are over a thousand trained young men to be cast aside as surplus junk? Can the interval be bridged without their help, and without loss to the engineering world? This is hardly conceivable; but if it is so, then why not sound the warning to the colleges to cut down on their engineering personnel? Let these men be guided into less crowded channels to be trained in other lines.

However, it does not seem probable that such is the case. Perhaps conditions are still so abnormal as to aggravate a usually healthy state of affairs. At the same time the problem is here and is a very serious one, not only from the remunerative standpoint, but also in its effect upon the morale of our young men. It is upon the shoulders of this type of young men that the burden rests of keeping a state of healthy normalcy in our country. Education is the best combative measure against bolshevism and anarchism. Any condition of affairs tending to break the spirit of these young men, to reduce them to a state of hopelessness and lethargy, will have its immediate effect upon their attitude toward such matters. They will not champion a state of affairs which they believe in their hearts to be unfair.

Engineers have in the past advocated a far-sighted policy. They have prepared for the future as well as the present. In this work they have been the pioneers, watching our resources, husbanding our reserves, and sounding the warning of waste and inefficiency. Can it be that they are now being overtaken by a wave of materialism; that they are no longer for what may affect the future as long as they make the most material gain in the present? These methods have been consistently condemned by engineers for many years. It is hard to believe they are coming to the same sort of policy against which they have so long fought. Yet why not prepare for the future in man reserve as well as machine and money reserve?

This is the question that is running through the mind of the graduate of today. What is your answer, Mr. Senior Engineer?

New York, N. Y. W. Cullin.

1921 Condensed Catalogues Being Distributed

The eleventh annual (1921) volume of Condensed Catalogues of Mechanical Equipment is now being distributed to the membership. This edition contains more than a hundred pages of catalogue data not included in the 1920 volume, important changes in the pages continued from last year, and a more comprehensive Directory Section, thoroughly revised and brought up to date with respect to the changes that have taken place during the past year.

There are 648 catalogue pages containing the condensed data of 495 firms. The arrangement of this data is uniform and convenient and includes descriptions of over 1300 pieces of apparatus, instruments, materials and the like—illustrated by over 1700 engravings. The indexing and classifying is thoroughly done so that the particular data sought can be instantly found.

The Mechanical Equipment Directory (green pages) contains the names and addresses of over 4000 firms under 3000 classifications of equipment. The names and addresses of over 700 consulting engineers in the Consulting Engineers Directory (yellow pages) appear under 400 classifications.

The volume may be purchased by non-members at $4.00 a copy plus 25 cents carrying charges. Extra copies for members may be had for $3.25.

THE ENGINEERING INDEX

(Registered U. S. Patent Office and Canadian Patent Office.)

THE ENGINEERING INDEX presents each month, in conveniently classified form, items descriptive of the articles appearing in the current issues of the world's engineering and scientific press of particular interest to mechanical engineers. At the end of the year the monthly installments are combined along with items dealing with civil, electrical, mining and other branches of engineering, and published in book form, this annual volume having regularly appeared since 1906. In the preparation of the Index by the engineering staff of The American Society of Mechanical Engineers some 1200 technical publications received by the Engineering Societies Library (New York) are regularly reviewed, thus bringing the great resources of that library to the entire engineering profession.

Photostatic copies (white printing on a black background) of any of the articles listed in the Index may be obtained at a price of 25 cents per page, plus postage. A separate print is required for each page of the larger periodicals, but wherever possible two small or medium-sized pages will be photographed together on the same print. The bill will be mailed with the print. When ordering photostats identify the article by quoting from the Index item: (1) Title of article; (2) Name of periodical in which it appeared; (3) Volume, number, and date of publication of periodical; (4) Page numbers. Orders should be sent to the Engineering Societies Library, 29 West 39th Street, New York.

ABRASIVE WHEELS

Phantom. Grinding with a Phantom Wheel, Ellsworth Sheldon. Am. Mach., vol. 55, no. 2, July 14, 1921, pp. 44–45, 5 figs. Difficulty of grinding thin work without heating. Wheel set at angle eliminates much of the pressure.

AERODYNAMICS

Testing Station. The Aerodynamic Experimental Station at Göttingen. Engineering, vol. 112, no. 2901, Aug. 5, 1921, pp. 218–220, 11 figs. Construction details of new experimental station. Translated from report entitled "Ergebnisse der Aerodynamischen Versuchsanstalt zu Göttingen," published by A. Oldenbourg, Munich and Berlin.

AEROPLANE ENGINES

Clearance Volumes. An Instrument for Measuring Clearance Volumes, H. C. Dickinson. A.S.R.E. Jl., vol. 7, no. 6, May 1921, pp. 460–463, 4 figs. Discusses aircraft-engine cylinders.

Fiat. 300 HP. Fiat Model A-12 Engine. Aerial Age, vol. 13, no. 18, July 11, 1921, pp. 415–416, 4 figs. Aviation engine said to resemble Mercedes 260-hp. engine. It has six vertical water-cooled cylinders and operates with gasoline as a fuel on four-stroke cycle.

AEROPLANE PROPELLERS

Theory. General Theory of Aeroplane Propellers (Théorie Générale de l'Hélice Propulsive), A. Rateau, M. R. Soreau and M. S. Drzewiecki. L'Aerophile vol. 29, nos. 9–10, May 1–15, 1921, pp. 139–146, 7 figs. Development of formulas and comparison with experimental results.

AEROPLANES

All-Metal. German Metal Airplanes (L'avion metallique en Allemagne), Roger Couturier. L'Aéronautique, vol. 3, no. 25, June 1921, pp. 249–254, 11 figs. Describes the Zeppelin-Staaken, Zeppelin-Dornier, also Dornier hydroplanes. (Concluded.)

Ansaldo Commerical Biplane. The Ansaldo A-300 C Commercial Biplane. Flight, vol. 13, no. 26, June 30, 1921, pp. 437–438. Specifications: Span, 44 ft. 9$^1/_2$ in.; chord, 6 ft. 6 in.; overall length, 31 ft. 8 in.; overall height, 10 ft. 9$^1/_2$ in.; total weight, 4187 lb.; useful load, 1653 lb.; speed range, 43–120 m p.h.; climb (15 min.), 7000 ft.

Balancing. Aeroplane Balance. L. Huguet. Aerial Age, vol. 13, no. 18, July 11, 1921, pp. 417–419 1 fig. Influence of wing profile and of passive resistance; influence of steering mechanism; sensitiveness of aeroplane to action of steering mechanism; equilibrium of forces. (Concluded.) Translated from "La Vie Technique & Industrielle."

Bristol Commercial. The Bristol Commercial Ten-Seater Biplane. Flight, vol. 13, no. 27, July 7. 1921, pp. 457–458, 3 figs. Characteristics: Span, 54 ft.; length overall, 42 ft.; height, 11 ft.; total weight as passenger machine, 6801 lb.; as cargo machine, 7100 lb.; speed at ground level full load, 122 m.p.h.; etc.

Farman. Farman Improved Aeroplane. Commonwealth Engr., vol. 8, no. 10, May 1, 1921, pp. 301–302, 1 fig. Specifications: Span, 23 ft. 4 in.; length, 20 ft. 11 in.; height 8 ft. 2$^1/_2$ in.; load-carrying capacity including pilot and passenger, 440 lb., equal to its own weight; engine, 60 hp.; max. speed 87 mi. per hr.; climb, 5000 ft. in 8 mm. 35 sec.

Fiat. Fiat 10 Passenger Airplane. Aviation, vol. 11, no. 5, August 1, 1921, pp. 139, 1 fig. Gives particulars of design and dimensions. Maximum speed 125 m.p.h.

Flotation Gear. DH-4 Emergency Flotation Gear. Aviation, vol. 11, no. 4, July 25, 1921, p. 103, 2 figs. Describes emergency flotation gear developed by Engineering Division of Army Air Service, consisting of a pair of collapsible fuselage air bags, front and rear hydro-surfaces, wing floats, wheel-releasing mechanism and an air system for inflation of flotation bags.

Fokker. The Commercial Monoplane "Fokker F.-III" (Le Monoplan Commercial "Fokker F-III"), Roger Couturier. L'Aéronautique, vol. 3, no. 26, July 1921 pp. 286–288, 2 figs. Made by Nederlandsche Vliegtuigenfabrik at Amsterdam. Description and comparative data.

Horsepower Chart. Aeroplane Flight Endurance—I. Aerial Age Weekly, vol. 13, no. 21, August 1, 1921, pp. 490–491, 1 fig. Describes a chart for determining minimum horsepower required or maximum horsepower available at any altitude possible for the aeroplane to reach.

Lift and Drag Coefficients. The Variation of Aerofoil Lift and Drag Coefficients with Changes in Size and Speed, Walter S. Diehl. Natl. Advisory Committee Aeronautics, Report No. 111, 10 pp., 8 figs. Results of investigation of existing scale-correction data and derivation of an original method for making these corrections rapidly and accurately.

Remington-Burnelli. The Remington-Burnelli Airliner. Aerial Age, vol. 13, no. 18, July 11, 1921, pp. 420–421 and 416, 3 figs. Specifications: Length overall, 41 ft. 2 in.; height, 18 ft.; span, 74 ft.; chord, 10 ft. 6 in.; horse power, 1000; climb, 900 ft. per min.; max. speed, 110 m.p.h.; etc.

Sablatnig P.3. The Sablatnig P.3 Monoplane. Flight, vol. 13, no. 31, August 4, 1921, pp. 521–525, 15 figs. Germany's first commercial aeroplane.

Saulnier Three-Engined Monoplane. The Saulnier Three-Engines Monoplane. Aviation, vol. 11, no. 3, July 18, 1921, pp. 71–72, 2 figs. Characteristics: Span, 93 ft.; length overall, 56 ft. 8 in.; height, 10 ft. 5 in.; max. chord, 19 ft. $^1/_4$ in.; wing area, 1300 sq. ft.; engines, 3500 hp. Liberty; weight loaded, 15,500 lb.; high speed, 150 m.p.h.; ceiling, 15,000 ft.

Spad. The Spad "Berline" S.33. Aerial Age Weekly, vol. 13, no. 21, August 1, 1921, pp. 488–489, 3 figs. The fuselage is of the monocoque streamline type, the wings baving a backswept top plane. Performance data.

Truss Ribs. Experimental Reinforced Plywood Truss Ribs. Aerial Age Weekly, vol. 13, no. 23, August 15, 1921, pp. 539–541, 10 figs. Compares plywood truss ribs with other types and draws conclusions based on tests. (To be continued.)

Wing Beams. Merits of Different Splices for Airplane Wing Beams. Jl. Soc. Automotive Engrs., vol. 9, no. 2, August 1921, pp. 133–138, 1 fig. Discusses the construction of the beam, also discusses scarf and splices and gives results of experiments.

Wing-Load Indicator. The Klemperer Wing-Load Indicator, Leon N. W. Colin. Aviation, vol. 11, no. 6, August 8, 1921, pp. 164–165, 1 fig. Description of operation and advantages.

[See also HYDROPLANES; PARACHUTES; SEAPLANES.]

AIR

Dust Content. Comparative Tests of Air Dustiness With the Dust Counter, Konimeter and Sugar Tube, S. H. Katz & L. J. Trostel. Jl. Am. Soc. Heat. & Vent. Engrs., vol 27, no. 5, July 1921, pp. 519–527 and (discussion) pp. 527–528, 8 figs. Particulars of comparative tests of air dustiness with dust counter, konimeter and sugar tube in granite-working plants.

AIRCRAFT CONSTRUCTION MATERIALS

Fabrics. Airship Fabrics, J. W. W. Dyer. Aeronautical Jl., vol. 25, no. 127, July 1921, pp. 332–348 and (discussion) pp. 349–356. Deals briefly with different types of fabrics, classified according to main functions of each, and describes their structure and behavior and chief factors affecting their permanence when in service.

AIRSHIPS

Masts. Airship Mast at Aerial Terminal in Pulham, Eng. (Le Mat d'Amarrage Pour Dirigeable de la Gare Aérienne de Pulham, Angleterre). Le Génie Civil, vol. 78, no. 24, June 11, 1921, pp. 493–496, 6 figs. Nose of airship is fastened to mechanism at top of mast. Mechanism is capable of rotating as airship is moved by wind.

Rigid. Rigid Airships, J. L. Bartlett. Aeronautical Jl., vol. 25, no. 127, July 1921, pp. 357–377, 8 figs. Two lectures, first dealing with general aerostatical principles governing flight of lighter-than-air craft, and describing various types of airships, with special reference to rigid airships; second referring to some important problems in design of rigid airship. Appendices.

ALIGNMENT CHARTS

Advantages. Note on Some Useful Alignment Charts, J. A. P. Gibb. Bul. Instn. Min. & Metallurgy, no. 200, May 1921, pp. 1–11, 6 figs. on supp. plates. Notes and chart presented with object of drawing attention to advantages which alignment charts offer as compared with the more commonly used intercept and correlation charts.

Uses. Alignment Charts—XIV, Arnold A. Arnold. Mech. World, vol. 70, no. 1880, July 1, 1921, pp. 9–10, 1 fig. Practical example: marine-engine shafts and crankshafts. Principal proportions of chart. Connection between charts. (Concluded.)

ALLOYS

See ALUMINUM ALLOYS; BEARING METALS; MONEL METAL.

ALUMINUM

Exposition, Paris. Exposition of New Industrial Application of Aluminum, Magnesium, Calcium and Sodium at the Société d'Encouragement, Paris (L'Exposition des Nouvellse Applications Industrielles de l'Aluminium, du Magnésium, du Calcium et de Sodium, à la Société d'Encouragement pour l'Industrie Nationale). Le Génie Civil, vol. 79, no. 2, July 9, 1921, pp. 36–39. Particulars of program of exposition and reports of four lectures on aluminum and its alloys.

Properties and Uses. Aluminum, Magnesium, Calcium and Sodium (L'aluminium, le magnésium, le calcium et le sodium). Revue Générale de l'Electricité, vol. 10, no. 1, July 2, 1921, pp. 21–29. Report of eight lectures given at the recent expo-

and their alloys.

ALUMINUM ALLOYS

Melting. Constitution of Gas Atmospheres in Aluminum-Alloy Melting Furnaces. Robert J. Anderson and J. H. Capps. Chem. & Metallurgical Eng., vol. 25, no. 2, July 13, 1921, pp. 54–60, 7 figs. Tabulated analyses of atmospheres of various types of aluminum furnaces, sampled at short intervals during operation, furnishing data necessary for study of dross and metal losses due to furnace operation.

Iron-Pot Melting Practice for Aluminium Alloys, Robert J. Anderson. Metal Industry (Lond.), vol. 19, nos. 1 and 4, July 1 and 22, 1921, pp. 8–9 and 65–66. Present-day methods and detailed investigation of them in practice. See also Metal Industry (New York), vol. 19, no. 7, July 1921, pp. 285–287, 4 figs.

Uses. Aluminium and Its Alloys in Engineering, John G. A. Rhodin. Engineer, vol. 131, no. 3417, June 24, 1921, pp. 659–660. Blowing and cracking of castings is attributed to overheating.

AMMONIA

Coke-Oven Gas as Source. Increasing the Ammonia Yield with the Distillation of Anthracite (Beiträge zur Erhöhung der Ammoniakausbeute bei der Destillation der Steinkohle), Friedrich Sommer. Stahl u. Eisen, vol. 41, no. 25, June 23, 1921, pp. 852–859, 5 figs. Process for recovery of hydrocyanic acid contained in coke-oven gas through conversion into ammonium sulphate.

Total Heat Diagrams. Total Heat Diagrams For Ammonia, E. F. Mueller and C. H. Meyers. A.S.R.E. Jl., vol. 7 no. 6, May 1921, pp. 419–425, 6 figs. Discusses the advantages of using total heat-entropy diagrams of which examples are given in rectangular and oblique coördinates, also total heat-pressure diagrams.

AMMUNITION

Colloided Smokeless Powder. Absorption of Moisture by Colloided Smokeless Powder, Tenney L. Davis. Army Ordnance, vol. 2, no. 1, July-August 1921, pp. 9–12, 2 figs. Discusses means of determining the hygroscopicity of the solvent-free material colloid and for comparing the hygroscopicity of various kinds of powder.

ARTILLERY

Post-War Matériel. Post-War Artillery Matériel G. F. Jenks. Army Ordnance, vol. 2, no. 1, July-August 1921, pp. 1–8, 13 figs. Discusses improvements due to the war and pending. Considers gun carriages and anti-aircraft material, motor material, etc.

ASH HANDLING

Plants. Ash-Handling Plant at Poplar Electric Power Station. Engineering, vol. 112, no. 2901, Aug. 5, 1921, pp. 231–233, 24 figs. Construction and operation of plant constructed by Underfeed Stoker Co., Ltd., London.

AUTOGENOUS WELDING

Boiler Repairs. Speeding Up Boiler Repairs by Use of Autogenous Welding Processes, C. E. Lester. Boiler Maker, vol. 21, no. 7, July 1921, pp. 194–195. Details of welding operations used in repairing flue sheets.

AUTOMOBILE ENGINES

Fuel Economy. Effect on Fuel Economy of Refinements in Engine Design, L. Mantell. Automotive Ind., vol. 45, no. 4, July 28, 1921, pp. 161–167, 9 figs. Discusses factors of design which affect performance and economy, such as pulsating flow, valve timing, scavenging, etc.

Localized Charge and Supercharging. Experiments with Localized Charge and Supercharging Engines, Harry R. Ricardo. Automotive Industries, vol. 45, no. 2, July 14, 1921, pp. 61–68, 18 figs. Report of investigations demonstrating how mean effective pressure and economy can both be increased by use of stratified charge. Excess air and cooled exhaust gas are employed as diluents to limit maximum temperature of cycle and prevent detonation. Unusually high fuel economy at part load is obtained by use of nonthrottling engine. (Abstract.) Paper presented before (British) Instn. Automobile Engrs.

AUTOMOBILE FUELS

Efficient Utilization. More Miles Per Gallon, O. C. Berry. Chem. & Metallurgical Eng., vol. 25, no. 2, July 13, 1921, pp. 64–68, 4 figs. Discussion on carburetion as affecting motor efficiency, brake horsepower and work. Spark timing and brake load. Relation between torque and engine speed. Possibilities of more efficient utilization of motor fuels. Paper read at Automotive Symposium, Am. Inst. Chem. Engrs.

[See also GASOLINE.]

AUTOMOBILES

Assembly System. Economy and Efficiency Increased by New Final Assembly System, Norman G. Shidle. Automotive Industries, vol. 45, no. 2, July 14, 1921, pp. 69–72, 8 figs. Describes new final assembly system and discusses methods of equipment.

Benz Chassis. One Four and One Six-Cylinder Chassis Comprise Benz Line, Benno R. Dierfeld. Automotive Industries, vol. 45, no. 2, July 14, 1921, pp. 56–60, 15 figs. Aside from engine, chassis are said to be practically identical and possess but few novel features. Transmission brake has provision for water cooling. Steering gear has unhardened screw with non-adjustable babbitt-lined nut.

Berliet. The 16–20 Hp. Berliet, Model VI, 1921. Auto, vol. 26, no. 27, July 7, 1921, pp. 580–583, 6 figs. Notable features are said to be the pressed steel bridge-type live axle; light but well-base torque-tube; well-extended rear suspension; adoption of dynamotor unit for lighting and starting; and grouping of all connections to concentric brakes.

Buick. New Buick Four Similar to Six of Same Make, J. Edward Schipper. Automotive Ind., vol. 45, no. 6, August 11, 1921, pp. 255–258, 6 figs. Description of design and equipment.

European vs. American Practice. Comparison of European and American Automobile Practice. Jl. Soc. Automotive Engrs., vol. 9, no. 2, August 1921, pp. 109–115 and Discussion 115–117. Comparison of general design, road conditions, etc.

Humber. The 15.9 Hp. Humber Chassis. Automobile Engr., vol. 11, no. 152, July 1921, pp. 234–241, 15 figs. Revised model of the 14-hp. design. A four-cylinder L-headed engine is employed with 80-mm. bore and 140-mm. stroke.

Kerosene Vaporizers. A Paraffin Vaporizer. Automobile Engr., vol. 11, no. 152, July 1921, pp. 252–253, 4 figs. New system for utilizing heavy fuel on commercial vehicles.

Leach. Far Western Custom Built Car Has Many Features. Automotive Mfr., vol. 43, no. 3, June 1921, pp. 7–10, 7 figs. Describes the Leach Six built by Leach Biltwell Motor Co., Los Angeles. Motor is specially built 6-cylinder unit of 3½-in. bore and 5¼-in. stroke, and 60 hp. at 2000 r.p.m.; weight, 3800 lb.

Locking Devices. Automobile Locking-Device Classification and Theft Insurance. Jl. Soc. Automotive Engrs., vol. 9, no. 2, August 1921, pp. 95–100 and Discussion pp. 100–106. Considers design factor in insurance and fire hazard.

Moller. Moller a New American Light Car. Motor Age, vol. 40, no. 2, July 14, 1921, pp. 18–19, 4 figs. Car designed along European lines weighs 850 lb.; chassis has 100-in. wheelbase and 50-in. tread.

Rolls-Royce. Some Unusual Features of the Rolls-Royce Car, Fred H. Colvin. Am. Mach., vol. 55, no. 3, July 21, 1921, pp. 85–86, 7 figs. Power transmitted through large ball joint. Bracing used at rear end of chassis. Axle and torque tubes made of steel forgings.

Star. The 11.9 Hp. Star. Auto, vol. 26, no. 28 July 14, 1921, pp. 600–602, 4 figs. Engine is monobloc with four cylinders 69 mm. by 120 mm. bore and stroke respectively; wheelbase is 9 ft. and track 4 ft.; wheels are 30 in. fitted with 3½-in. tires.

Transmission Cases. Machining and Inspecting Transmission Cases, Fred H. Colvin. Am. Mach., vol. 55, no. 4, July 28, 1921, pp. 143–147, 23 figs. Fixtures hold aluminum cases without springing. Drilling and tapping operations. Inspection gages that insure accurate alignment.

Transmission Gear. Machining the Wrigley Automobile Transmission Gear I and II, I. W. Chubb. Am. Mach., vol. 55, nos. 5 and 7, Aug. 4 and 18, 1921, pp. 176–178 and 252–255, 17 figs. Aug. 4: Modern production methods in English plant. Forms necessary for accurate record keeping. Aug. 18: Using mechanical conveyors to eliminate handling progressive machining of automobile parts. Inspection tools and methods for rough and finished parts.

Voiturette. The 10 Hp. B.A.C. Auto-Motor Jl. vol. 26, no. 31, August 4, 1921, pp. 665–668, 7 figs. Description of a voiturette made by the British Automotive Company.

AVIATION

Aerial Transportion. Value of Airplanes in Transportation (De la Valeur de l'Avion Comme Engin de Transport), L. Hirschauer. L'Aeronautique, vol. 3, no. 25, June 1921, pp. 255–258, 2 figs. Discusses security, regularity, speed, stops, etc. (To be continued.)

Commercial. Commercial Aviation in Germany, Erik Hildesheim. Aviation, vol. 11, no. 5, August 1, 1921, pp. 135–136, 1 fig. Considers conditions of subsidy, planes under construction, air transport service and passenger rates.

Luminous Beacons. Luminous Beacons on Aerial Routes For Nocturnal Flying (Le balisage lumineux des routes aeriennes pour la navigation nocturne). Le Genie Civil, vol. 79, no. 5, July 30, 1921, pp. 111–112, 2 figs. (From l'Aerophile.) Discusses lighthouses with fixed and intermittent light signals.

AXLES

Machining Methods. Machining Front Axles. Eng. Production, vol 3, no. 40, July 7, 1921, pp. 4–6, 7 figs. Methods employed for intensive production.

B

BEAMS

Reinforced-Concrete. Reinforced-concrete Beams —II. T. C. Broom. Mech. Wld., vol. 70, no. 1803, July 22, 1921, pp. 68–69. Discusses rectangular concrete beam with double reinforcement. (To be continued.)

Strength of the Reinforced Thin-plate Beam, Held at Its Ends, and Subject to a Uniformly Distributed Load—Special Case, B. C. Laws. London, Edenburgh and Dublin. Phil. Mag. & Jl. of Sci., vol. 42, no. 248, 6th series, August 1921, pp. 281–287, 3 figs. Continuation of a mathematical investigation started in a previous paper.

BEARING METALS

Properties at High Temperatures. Properties of White Metal Bearing Alloys At Elevated Temperatures, John R. Freeman Jr. and R. W. Woodward. Raw Material, vol. 4, no. 7, July 1921, pp. 241–245, 7 figs. Describes tests carried out by the Bureau of Standards on five alloys.

BEARINGS, BALL

Manufacture. A Modern Ball Bearing Works. Eng. Prod., vol. 3, no. 44, August 4, 1921, pp. 108–115, 24 figs. Production methods on accurate repetition work. Description of works of Rudge-Whitworth, Ltd., Sparkhill, Birmingham.

BELTING

Balata. Balata and Fabric-Belt Formulas and Chart, W. F. Schaphorst. Power Plant Eng., vol. 25, no. 15, August 1, 1921, pp. 769–770.

Rubber. Revised Rubber Belt Specifications Adopted by A.S.T.M. Belting, vol. 19, no. 1, July 1921, pp. 13–14, 1 fig. Principal changes provide for increase in allowable stretch from 5 to 6 per cent and reduction of ultimate strength from 285 to 260 lb. Revised specification submitted by Am. Soc. Testing Materials.

BLAST FURNACES

Electric. The Metallurgy of Electric Blast Furnaces (Ueber die Metallurgie des Elektrohochofens), R. Durrer. Stahl u. Eisen, vol. 41, no. 22, June 2, 1921, pp. 753–757, 1 fig. Discussion of certain metallurgical phenomena in electric blast furnaces with special regard to work of Bo Kalling (see Jernkontorets Annaler, 1919, pp. 413–430) dealing with hot and cold working; part played by direct and indirect reduction in total reduction.

BOILER EXPLOSIONS

Causes. Boiler Explosion at a London Hospital. Engineering, vol. 112, no. 2899, July 22, 1921, pp. 148–149. Report issued by Board of Trade states that explosion was primarily due to generation of excessive pressure in boiler consequent upon fire being lit in boiler with all outlets closed and relief valve inoperative.

BOILER FEEDWATER

Treatment. Power Plant Management—I, Robert June. Refrigerating World, vol. 56, no. 7, July 1921, pp. 21–23. Notes on boiler-water treatment. Specifications for ideal water-purification plant.

BOILER PLANTS

Modernizing. Modernizing a Cotton Mill Boiler Plant, Charles T. Main. Textile World, vol. 60, no. 6, August 6, 1921, pp. 87–89, 4 figs. Change from hand firing to stoker firing.

BOILER TUBES

Charcoal Iron. The Manufacture of Charcoal Iron Boiler Tubes. Boiler Maker, vol. 21, no. 7, July 1921, pp. 187–190 and 212, 9 figs. Methods and machines employed by Parkesburg Iron Co.

BOILERS

Accessories. Boiler Accessories from a Safety View Point. Power House, vol. 14, no. 14, July 20, 1921, pp. 28–31. Discusses various mountings of the modern boiler and makes suggestions for greater safety.

Code Rulings, Pennsylvania. Boiler Code Rulings of Pennsylvania Board. Boiler Maker, vol. 21, no. 7, July 1921, pp. 196–197. Use of autogenous welding in boilers outlined. Inspection and standard stamping of boilers. Rulings adopted May 24, 1921, by Industrial Board, Dept. of Labor and Industry, Pa.

Combustion and Efficiency. Theory of Combustion and Efficiency of Steam Boilers, Arthur R. Norris. Practical Engr., vol. 63, no. 1792, June 30, 1921, pp. 412–413. Gives empirical formula for calculation of calorific value of any fuel when chemical composition is known. Calculation of loss of heat in boilers.

Inspection. Inspecting the Boiler, W. M. McNeill. Power Plant Eng., vol. 25, no. 15, Aug. 1, 1921, pp. 752–753. What to look for and where to look for it.

Losses. Minimizing Steam Boiler Losses—III, Robert June. Gas Age, vol. 48, no. 1, July 11, 1921, pp. 7–9. Notes on steam-power management.

BOMBING

Aeroplane. Airplane Bombing, E. J. Loring. Army Ordnance, vol. 2, no. 1, July-August 1921, pp. 21–22, 3 figs. Discusses trajectory and accuracy of aim.

BRAKES

Hand. Efficient Hand Brakes for Freight Cars, Frank N. Grigg. Southern and Southwestern Ry. Club, vol. 16, no. 3, May 19, 1921, pp. 10–34, 5 figs. General description, causes of accidents, up-keep.

BRASS

High-Resistance. High-Resistance Brass, Pendleton Powell. Metal Ind., (Lond.), vol. 19, no. 4, July 22, 1921, pp. 62–64. Discusses molding, melting, pouring, use of scrap, etc.

Season Cracking. The Season-Cracking of Brass and Other Copper Alloys, H. Moore. Engineering, vol. 112, no. 2902, Aug. 12, 1921, pp. 262–264, 9 figs. Results of investigation of season cracking carried during period of some years by Research Department, Woolwich, England. (Abstract.) Paper read before Inst. Metals. (To be continued.)

BRONZE

Manganese. Methods of Casting Manganese-Bronze Test Bars as a Check on Melts of Small Castings, E. H. Dix, Jr. Metal Ind., vol. 19, no. 8, August 1921, pp. 315–317, 2 figs. Results of experiments made to fix upon a satisfactory method.

BUILDING CONSTRUCTION

Bush Buildings, London. Construction Features in the Bush Buildings, London. Am. Architect, vol. 120, no. 2372, July 20, 1921, pp. 53–60, 12 figs. 30,000 cu. yd. of earth were excavated for foundations and basement. Details of sidewalk vaults, walls and footings, steel framing, etc.

BUILDINGS

Acoustics. Acoustical Properties of Buildings, F. R. Watson. Jl. Western Soc. Engrs., vol. 26, no. 7, July 1921, pp. 241–247, 3 figs. It is shown that one important problem in acoustics of buildings lies in sound proofing of various rooms.

Office. Fire Resistive Construction of Office Buildings, Fire & Water Eng., vol. 70, no. 4, July 27, 1921, pp. 154–155, 163 and 169. Report of Nat. Fire Prot. Assoc. Committee on building construction.

Steel-Frame. Reducing the Cost of Steel-Frame Buildings, R. Fleming. Eng. & Contracting, vol. 56, no. 4, July 27, 1921, pp. 83–86. Considers the questions of design, specifications and standardization in this connection.

C

CABLES

Aerial. Suspension Cables and Their Use in Construction (Les Cables de Suspension et leur emploi dans la construction). Le Génie Civil, vol. 79, no. 3, July 16, 1921, pp. 59–63, 11 figs. Describes the manufacture of cables and gives illustrations of their application.

CABLEWAYS

French. The Cableway in Hohneck (Alsace) (Die Drahtseilbahn am Hohneck). Fördertechnik u. Frachtverkehr, vol. 14, no. 6, Mar. 18, 1921, pp. 71–72. Describes cableway of the French army for transportation of supplies to the front line.

CALORIMETERS

Coal. The Calorimetry of Solid Fuel—III. Eng. & Ind. Management, vol. 6, no. 3, July 21, 1921, pp. 62–64, 3 figs. Deals with the Wm. Thompson, Rosenhain and Darling calorimeter.

Fairweather Gas-Testing. The "Fairweather" Recording Calorimeter. Gas Jl., vol. 154, no. 3031, June 15, 1921, pp. 628–629, 2 figs. Results of tests with described instrument show that it gives a continuous record within $1/2$ per cent of accuracy.

Simmance Recording. Fifth Report of the Research Sub-Committee on the Gas Investigation Committee of the Institution of Gas Engineers. Gas Jl., vol. 154, nos. 3032, 3033, June 22 and 29, 1921, pp. 677–684 and 744–750 and vol. 155, no. 3034 and 3035, July 6, and 13, 1921, pp. 35–40 and 101–103, 22 figs. The Simmance recording calorimeter.

Solid Fuel. The Calorimetry of Solid Fuel—II. Eng. & Indus. Management, vol. 5, no. 26, June 30, 1921, pp. 737–739, 3 figs. Operating method of some of best-known solid fuel calorimeters are explained and explanitory diagrams are given.

CAR LIGHTING

Testing. Principles of Car Lighting by Electricity —XII, Charles W. T. Stuart. Ry. Elec. Engr., vol. 12, no. 7, July 1921, pp. 278–282, 7 figs. Testing and adjusting a car-lighting equipment.

CAR WHEELS

Failures. Studies Failures of Cast-Iron Wheels, H. J. Force. Foundry, vol. 49, no. 15, August 1, 1921, pp. 602–603. Limits recommended for composition of metal based on analyses of failures.

CARBOCOAL

Smith Carbonization Process. The Smith Continuous Carbonization Process. Engineering, vol. 112, no. 2900, July 29, 1921, pp. 175–179, 10 figs. Describes process developed by C. H. Smith, New York, according to which coal is first subjected to low-temperature distillation, after which solid residue is again treated at high temperature to produce hard fuel known as carbocoal. Details of plant at Clinchfield, Va.

CARBURETORS

Automaticity. Principles of Automatic Action In Carburetors (Les Principes d'Automaticité des Carburateurs). La Vie Automobile, vol. 17, no. 732, June 25, 1921, pp. 223–225, 6 figs. Discusses supplementary air supply, simultaneous control of air and gasoline flow, diffusers, etc.

Fundamentals. Fundamental Points of Carbureter Action, F. C. Mock. Jl. Soc. Automotive Engrs., vol. 9, no. 2, August 1921, pp. 85–94, 11 figs. Considers the joint responsibility of the engine designer and the carbureter engineer, and of the latter to produce an instrument that will deliver reliably and consistently a fuel charge with as favorable vaporization conditions as can be obtained.

CARS

All-Metal. New All-Metal Cars in Use on English Railway, F. C. Coleman. Elec. Traction, vol. 17, no. 7, July 1921, pp. 468–470, 3 figs. Cars built by Lancashire & Yorkshire Ry. Details of electrical equipment; automatic control; brake equipment; and interior construction.

All-Steel High-Capacity. New All-Steel Wagons for Bengal-Nagpur Railway. Ry. Engr., vol. 42, no. 498, July 1921, pp. 273–275, 4 figs. Details of high-capacity wagons constructed by Midland Ry. Carriage & Wagon Co., Ltd., Birmingham, for India. Dimensions: Extreme length over buffers, 49 ft. 2 in.; width over underframe solebars, 9 ft. 6 in.; center of bogies, 32 ft.; bogie wheelbase, 6 ft.; buffer height, 3 ft. $7^1/_2$ in.; load, 40 tons.

Dining. New Dining and Kitchen Carriages Built at Derby for the Midland and Glasgow & South Western Railways' Joint Services. Ry. Gaz., vol. 35, no. 3, July 15, 1921, pp. 128–137, 12 figs. 1 supp. pl. Particulars of dimensions and equipment.

Suspension Method. Study of a New Suspension Method for Railway Cars, (Etude d'une nouvelle Suspension pour Matérial Roulant), M. Lotte. L'Industrie des Tramways, vol. 15, no. 171–172, March-April 1921, pp. 51–53, 1 fig. (Concluded.)

CARS, FREIGHT

Concrete. New Reinforced-Concrete Freight Cars (Neue Eisenbahnwagenbauten in Eisenbeton), Gerhard Neumann and Franz Lehner. Beton u. Eisen, vol. 20, no. 2–3, Feb. 4, 1921, pp. 32–34, 6 figs. Details of the first Hungarian reinforced-concrete cars type Kmu; and the Austrian cars type Ke.

Design. Factors To Be Considered in Freight Car Designing, Albert H. Lake, Jr. Ry. Mech. Engr., vol. 95, no. 8, August 1921, pp. 495–496. Arranging details to reduce cost of construction and maintenance and avoiding troublesome defects.

Draft-Gear Tests. Draft-Gear Tests of the Railroad Administration. Ry. Mech. Engr., vol. 95, no. 8, August 1921, pp. 497–501, 8 figs. Results of car impact tests, comparative grading of gears and general conclusions.

CARS, TANK

Reinforced-Concrete. Reinforced-Concrete Tank Cars (Zisternenwagen aus Eisenbeton), Viktor Lazarus. Beton u. Eisen, vol. 20, no. 6, Apr. 4, 1921, pp. 69–70, 4 figs. Details of French tank cars of reinforced concrete for transportation of petroleum, wine, etc.

CASE-HARDENING

High-Temperature Resisting Alloys. High Temperature Resisting Alloys for Carbonizing, A. Bensel. Trans. Am. Soc. Steel Treating, vol. 1, no. 10, July 1921, pp. 598–601. Sets forth desirability of good heat-resisting containers, and discusses standard methods of case hardening employing these containers, namely, pack, liquid bath and gas carbonizing.

CAST IRON

Shrinkage and Piping. The Shrinkage and Piping of Cast-Iron (Schwinden und Lunkern des Eisens), Karl Sipp. Stahl u. Eisen, vol. 41, no. 26, June 30, 1921, pp. 888–890, 2 figs. Supplement to author's article in same journal (Apr. 24, 1921, pp. 675–680), in which theory of shrinkage and piping was developed.

Spiegeleisen, Influence of. Influence of Speigeleisen and Phosphorus Spiegeleisen on Cast Iron (Einfluss von Spiegel- bzw. Phosphorspiegeleisen auf das Gusseisen), E. Schultz. Giesserei-Zeitung, vol. 18, nos. 10 and 12, May 15 and June 15, 1921, pp. 152–155 and 197–200, 3 figs. Based on operating experiences in the Luise Mine in Lünen, Germany, writer explains effect of increase in content of manganese in charge in connection with melting in cupolas caused by addition of spiegeleisen and phosphorus spiegeleisen. Address delivered before Assn. German Steel Works Engrs.

CASTINGS

Cracks, Annular. Annular Cracks, R. R. Clarke. Metal Industry (Lond.), vol. 19, no. 1, July 1, 1921, pp. 2–3, 10 figs. Discussion of various theories accounting for their formation.

CEMENT

Hardening. Law of Hardening of Cement, (Loi de durcissement du Ciment), J. Bied and E. Garnier, Revue de l'Ingénieur, vol. 28, no. 6, June 1921, pp. 269–272, 1 fig. Graph constructed from results of experiments.

Oxychloride. Plastic Calcined Magnesite and Oxychloride Cements, M. Y. Seaton. Chem. & Met. Eng., vol. 25, no. 6, August 10, 1921, pp. 233–236, 1 fig. Physical tests showing and factors influencing the properties of oxychloride cements.

Rapid-Setting. Rapid-Setting Cement (Béton à pris accélerée des fermes du Comptoir suisse d' Echantillons de Beaulieu), A. Paris. Bulletin Technique de la Suisse Romande, vol. 47, no. 15, July 23, 1921, pp. 169–172, 7 figs. Results of tests carried out with Holderbank cement to produce a cement which will harden in ten days instead of the usual 28.

Tests. Tests for the Determination of the Variations of Volume of Cement and Cement Mortar During Setting (Versuche zur Ermittlung der Raumänderungen von Zement und Zementmörtel beim Abbinden, Etc.), Otto Graf. Beton u. Eisen, vol. 20, nos. 4–5 and 6, Mar. 7 and Apr. 4, 1921, pp. 49–52 and 72–74, 12 figs. Influence of water addition, mixture ratio, and cement on extent of volume variations. Measurement of change of length of reinforcement with setting of cement mortar. Investigations of the swelling and contracting of natural stones with moisture and by drying.

CEMENT, PORTLAND

Crushing Plant. Perfect Dry-Mix Control. Rock Products, vol. 24, no. 15, July 16, 1921, pp. 20–28, 29 figs. Details of new crushing plant of Giant Portland Cement Co. at Egypt, Pa.

Coal-Fired. The Economic Limits of Distribution from Coal-fired Stations, William B. Woodhouse. Engineering, vol. 112, no. 2898, July 15, 1921, p. 128, 1 fig. Consideration of steps to be taken to supply an area which extends beyond economical limits of distribution pressure in use. Paper read before Instn. Civ. Engrs.

Equipment. Modern Tendencies in Central Station Construction (Les Tendences Modernes dans la Construction des Centrales), F. Scoumanne. Revue Universelle des Mines, vol. 9, no. 4, May 15, 1921, pp. 346–355. Describes machinery and switchboard equipment.

CHIMNEYS

Brick, Loss of Heat in. Loss of Heat in Brick Chimneys, Alfred Cotton. Power Plant Eng., vol. 25, no. 15, August 1, 1921, pp. 747–748. An investigation into the effect of air infiltration on heat loss.

COAL

Volatile Content. Determination of Volatile Matter in Coal (Determination de la Teneur en Matières Volatiles), Auguste Dessemond. Revue de l'Industrie Minerale, no. 13, July 1, 1921, pp. 451–456. Develops a formula for calculating volatile matter from ash content.

Volatile Matter in Coal (Les Matières Volatiles de la Houille), Achille Delclève. Chimie & Industrie, vol. 6, no. 1, July 1921, pp. 33–40, 5 figs. Shows that present methods require revision.

COAL HANDLING

Plant. A Modern Coal-Handling Plant. Managing Engr., vol. 8, no. 3, July 1921, pp. 47–52, 6 figs. Describe a mechanical coal-handling plant that involves avoidance of waste and will operate day and night, so long as the necessary driving power is available.

Pneumatic Plant. The Pneumatic Handling of Coal. Elecn., vol. 86, no. 2249, June 24, 1921, pp. 801–803, 4 figs. Describes pneumatic plant for discharging coal from barges, constructed by Henry Simon, Ltd.

COAL STORAGE

Submerging in Pits. Concrete Pits for Submerging Reserve Coal Supply. Elec. Rev., vol. 79, no. 5, July 30, 1921, pp. 163–164, 2 figs. Dangers of spontaneous combustion are eliminated and drippage basin is provided by means of which screenings are saved.

COKE

Foundry Slag and, Characteristics of. Characteristics of Foundry Cokes and Slags, Y. A. Dyer. Iron Age, vol. 108, no. 7, Aug. 18, 1921, pp. 407–409. Analyses, units of value and tests. Analyses and value of fluxes. Slagging. Nature of slags and value of melting process.

COKE BREEZE

Boiler Fuel. Coke Breeze Mixtures for Steaming —II, John Blizzard and James Neil. Coal Trade Jl., vol. 52, no. 29, July 20, 1921, pp. 845–846, 2 figs. Tests show advantages of combining breeze with bituminous coal under hand-fired boilers.

Burning Coke Breeze with Mechanical Stokers, William H. Burton. Coal Industry, vol. 4, no. 7, July 1921, pp. 331–333. Successful handling of low-grade fuels in a boiler plant.

COKE-OVEN GAS

Benzol in. Determination of Benzol in Coke-Oven Gas, A. Thau. Part I. Blast Furnace & Steel Plant, vol. 9, no. 8, August 1921, pp. 474–476, 1 fig. Describes European methods of determining benzol. (To be continued.)

COLUMNS

Design. Calculation of Columns (Le Calcul des Colonnes), L. Lemaire. Annales des Travaux Publics de Belgique, vol. 22, series 2, June 1921, pp. 367–384, 12 figs. Develops formulas for wind pressures. (To be continued.)

Fire-Resistance Tests. Fire Resistance of Building Columns as Shown by Test, R. E. Wilson. Eng. News-Rec., vol. 87, nos. 3 and 4, July 21 and 28, 1921, pp. 106–110 and 145–146, 5 figs. Conclusions drawn from test series of 106 columns caried out during 1917–18 show cast iron and timber resist longer than unprotected steel. How various fireproofing materials fail. Concrete makes best showing.

COMBUSTION

Alignment Charts for Fuel. Calculating Charts for the Combustion of A Given Fuel (Rechentafeln für die Verbrennung beliebiger Brennstoffe), Wa. Ostwald. Feuerungstechnik, vol. 9, no. 19, July 1, 1921, pp. 173–177, 9 figs. Writer develops a universal alignment chart which can be used directly for every fuel, or from which special charts can be plotted.

Control. Report of the Exposition of Combustion-Controlling Devices (Compte Rendu de l'Exposition des Appareils de Controle de la Chauffe), P. Frion. Société des Ingénieurs Civils de France, vol. 74, nos. 1, 2, 3, January-March 1921, pp. 7–34, 21 figs. Covers manometers, flow meters, feedwater meters, thermometers and pyrometers, flue-gas analysis, calorific power of coal, etc.

CONCRETE

Age, Effect of. Effect of Age on the Strength of Concrete, Duff A. Abrams. Concrete, vol. 19, no. 1, July 1921, pp. 14–15, 2 figs. Based on careful study of available data, writer states with utmost confidence that under normal conditions, concrete in roads does not deteriorate in strength with age.

Aggregates. A Study of the Composition of Blast-Furnace Slags Suitable for Concrete Aggregate, L. G. Carmick. Eng. & Contracting, vol. 56, no. 4, July 27, 1921, pp. 82–83, 2 figs. Describes tests made for the purpose.

Crusher Screenings, Effect of. Effect of Crusher Screenings in Concrete, Walter C. Adams and James G. Ross. Cement News, vol. 33, no. 7, July 1921, pp. 19–21, 1 fig. Increase in strength of concrete

through use of up to 20 per cent of crusher screenings in aggregate. Economic advantage of utilizing screenings. Report on tests carried out by Milton Hersey Co., Ltd., Montreal.

Elasticity, Modulus of. The Modulus of Elasticity on Concrete, F. C. Lea. Concrete & Constructional Eng., vol. 16, no. 7, July 1921, pp. 435–439 and (discussion) pp. 439–441. 2 figs. Results from compressometer tests show that mixtures in which ration of sand to stone are 1:1 and 1:1½ are not to be recommended, but only mixtures with ratio of 1 : 2, properties of which are summarized. (Abstract.)

Proportioning. Proportioning Concrete By Voids in the Mortar, Arthur N. Talbot. Eng. News-Rec., vol. 87, no. 4, July 28, 1921, pp. 147–152, 8 figs. Proposed method of estimating density and strength of concrete and of proportioning materials by experimental and analytical consideration of voids in mortar and concrete. (Abstract.) Paper presented before Am. Soc. for Testing Materials.

Three Methods of Proportioning Concrete. Eng. & Contracting, vol. 56, no. 4, July 27, 1921, pp. 87–91, 12 figs. Discusses Abrams' water-cement-ratio strength relation, Edward's surface area method of proportioning, Hydro-Electric Power Commission method of proportioning.

Setting Time. Time of Set of Concrete, Watson Davis. Eng. & Contracting, vol. 56, no. 4, July 27, 1921, pp. 79–81. Considers the influence of character of cement, also time and temperature, flow-set method, etc.

Waterproofing. Waterproofing Concrete—III, J. H. Burgess. Commonwealth Engr., vol. 8, no. 10, May 1, 1921, pp. 306–307. Notes on permeability tests. (Concluded.)

CONCRETE, REINFORCED

Design. Suggestions for Concrete Design, Harold A. Axtell. Can. Engr., vol. 40, no. 26, June 30, 1921, pp. 1 and 5, 2 figs. Types of live loads for different buildings. Standardization of design. Three systems of slab design and their relative cost.

CONDENSERS, STEAM

Cleaning Tubes. Cleaning Surface Condenser Tubes D. W. R. Morgan. Elec. Jl., vol. 18, no. 7, July 1921, pp. 313–315, 7 figs. Discusses eight types and methods of cleaning.

Corrosion. Corrosion in Condensers, Ernest Bate. Commonwealth Engr., vol. 8, no. 11, June 1, 1921, pp. 339–343, 8 figs. Discusses results of investigation and experiments of the condensers of the Ultimo & White Bay power houses, Sydney, N.S.W.

CONVEYORS

Belt. Interlocking Belt Conveyor System, A. M. Beebe. Gas Age-Rec., vol. 48, no. 3, August 6, 1921, pp. 105–107, 7 figs. Description of the electrically driven automatic system of the Rochester Gas & Electric Corp.

COST ACCOUNTING

Construction Work. Cost Accounting System for Construction Work, W. N. Connor. Eng. & Contracting, vol. 56, no. 3, July 20, 1921, pp. 66–70, 9 figs. Notes on use of daily labor cost reports; summary and analysis of estimate; timekeeping symbols and field sheet; waste and payroll sheets; invoice and material cost records; tabulating job cost by graphic method; final cost summary and cost comparison. (Abstract.) Paper presented before Boston Soc. Civ. Engrs.

Foundries. The Costing Problem in the Foundry, O. Bertoya. Metal Industry (Lond.), vol. 19, no. 2, July 8, 1921, pp. 21–24. Notes on indirectly apportionable expenses and overhead charges; inspection; and records.

Methods. Necessity of Proper Cost Accounting, J. B. Sehl. Iron Age, vol. 108, no. 7, Aug. 18, 1921, pp. 391–393. Machine-rate or production-center method stressed. Distribution of overhead in bulk or by department. Why some methods fail.

Principles and Advantages. The Necessity of Proper Cost Accounting, J. B. Sehl. Forging & Heat-Treating, vol. 7, no. 7, July 1921, pp. 370–372. Describes principles of cost accounting and explains its advantages. Primary purposes of cost accounting are summarized as follows: (1) to ascertain actual costs; (2) to forecast in order to fix future selling prices; (3) to reduce costs; and (4) to increase efficiency.

Work-in-Progress Account. The Work-in-Progress Account: An Essential Feature in Modern Costing. Robert Stelling. Eng. & Indus. Management, vol. 5, no. 26, June 30, 1921, pp. 734–736, 1 fig. Notes on relation of turnover and finances, cost of idle time, etc.

COSTS

Engineering, Rise in. Rise in Engineering Costs—II, R. J. A. Pearson. Eng. & Indus. Management, vol. 5, no. 26, June 30, 1921, pp. 740–742, and vol. 6, no. 1, July 7, 1921, pp. 11–13, 5 figs. Data contained in paper read before Roy. Statistical Soc. on comparison of pre-war and post-war costs in engineering.

CRANES

Floating. Derricking Jib Type Floating Crane Mammouth. Marine Eng., vol. 26, no. 8, August 1921, pp. 591–592, 2 figs. 200-ton floating crane for the port of Liverpool.

Foundry. 25-ton Electric Overhead Foundry Crane. Engineer, vol. 131, no. 3417, June 24, 1921, pp. 667–668, 5 figs. Span is 47 ft. between centers of rails, maximum available head room 7 ft. 10 in. and end clearance 10 in.

Handling Materials in a Remodeled Foundry. Iron Age, vol. 108, no. 2, July 14, 1921, pp. 76–78, 4 figs. New crane installations saved in a year over double their cost.

Safety Devices. Crane Safety Devices, Nicholas Prakken. Safety Eng., vol. 42, no. 1, July 1921, pp. 27–30. Deals with safety devices on class of cranes used in foundries, machine shops, yards, shipways and warehouses.

Traveling. Electric Motor Drive for Traveling Cranes, Gordon Fox. Blast Furnace and Steel Plant, vol. 9, nos. 7 and 8, July and Aug. 1921, pp. 413–416 and 485–488, 3 figs. Discusses question of manual control versus magnetic control for cranes.

Wharf. Motor-Operated Cranes Used for Cargo Transfer, Henry Cunningham. Elec. Rev. (Chicago) vol. 79, no. 3, July 16, 1921, pp. 90–92, 2 figs. Describes two Shaw overhead wharf cranes installed at pier on East River, New York City.

CUPOLAS

Chemical Reactions. Chemical Reactions in Foundry Cupolas, Y. A. Dyer. Iron Age, vol. 108, no. 5, Aug. 4, 1921, pp. 259–262. Actions and reactions. Combustion, cupola gases, carbon ratio, melting efficiency, metal losses and gains. Cupola balance sheet.

Use in Open-Hearth Practice. Use of Cupolas in Open-Hearth Practice, V. W. Aubel. Iron Age, vol. 108, no. 7, Aug. 18, 1921, pp. 403–405. Melting high-silicon and other pig iron continuously and supplying hot metal to four 60-ton basic open-hearth furnaces.

CUTTING TOOLS

Lathe and Planer. Design of Lathe, Planer, Shaper and Slotter Tools. Can. Machy., vol. 26, no. 3, July 21, 1921, pp. 33–36, 10 figs. Factors which decide what shape of tool will prove most efficient for any given cutting operation.

The Lumsden System for Lathe-Type Tools. Engineering, vol. 112, nos. 2900 and 2901, July 29 and Aug. 5, 1921, pp. 183–186 and 213–216, 17 figs. Details of the Lumsden oscillating grinder with settings required for some of the tools given in table.

CYLINDERS

Calculation. The Calculation of Thick and Thin Cylinders. Machy. (Lond.), vol. 18, no. 458, July 7, 1921, pp. 421–422, 5 figs. Calculating method and examples.

DIES

Trimming. Construction and Action of New Trimming Die. Can. Machy., vol. 25, no. 24, June 16, 1921, pp. 40–41, 4 figs. Describes patented tool that trims surplus metal. In place of downward movement of punch a lateral oscillating movement accomplishes operation.

DIESEL ENGINES

Construction. Building Diesel Engines on the Pacific Coast, Frank A. Stanley. Am. Mach., vol. 55, no. 2, July 14, 1921, pp. 41–43, 12 figs. How principal parts are machined. Good system for keeping order in shop handling big work.

Generator Driving. Diesel Engines for Generator Driving, C. S. Darling. Beama, vol. 9, no. 1, July 1921, pp. 41–45. Construction, operation, maintenance, etc. (Concluded.)

Investigations. Investigations of Diesel Engines—II (Untersuchungen an der Dieselmaschine), Kurt Neumann. Zeit. des Vereines deutscher Ingenieure, vol. 65, no. 30, July 23, 1921, pp. 801–804, 10 figs. Results of tests for determination of condition during combustion period and interchange of heat between gas and wall of engine cylinder. The separate phases of combustion are quantitatively determined, and the speed of combustion is established.

Lubrication. Lubrication of Marine Diesel Engines, Louis R. Ford. Marine Eng., vol. 26, no. 8, August 1921, pp. 623–627, 4 figs. Discusses low-pressure and high-pressure systems, cylinder lubrication, selection of oil, oil filters, etc.

Manufacture. Four-Cycle Diesel Engine Specialists. Steamship, vol. 33, no. 385, July 1921, pp. 15–21, 9 figs. Notes on manufacture of Diesel engines by firm of Burmeister & Wain, Ltd., Copenhagen. Gives list of motorships built by firm.

Marine. Injection and Combustion of Fuel-Oil, Part V., C. J. Hawkes. Motorship, vol. 6, no. 8, August 1921, pp. 655, 1 fig. Experiments with solid-injection and air-blast in marine Diesel engines. (To be continued.)

Problems in the Manufacture of Internal-Combustion Engines, John Holloway. Shipbuilding & Shipping Rec., vol. 18, no. 1, July 7, 1921, pp. 13–14. Suggestions on choice of material and best methods of machining various parts of marine Diesel engines.

The Use of Diesel Engines for the Drive of Deep-Sea Fishing Vessels (Verwendung von Dieselmotoren als Antriebsmaschinen für Hochsee-Fischereifahrzeuge), H. Wölke. Schiffbau, vol. 22, no. 38–39, June 22–29, 1921, pp. 917–921, 4 figs. Writer points out advantages and recommends replacing steam engines in older fishing steamers with former U-boat Diesel engines or with described 250-hp. Diesel engine.

Nobel. Development of the Nobel Diesel-Engine, Edwin Lundgren. Motorship, vol. 6, no. 8, August 1921, pp. 648–649, 4 figs. Reviews past work and describes progress of the two-cycle system. (To be continued.)

Recent Progress. Recent Progress in Large Diesel Engines for the Mercantile Marine, James Richardson. Engineering, vol. 112, no. 2899, July 22, 1921, p. 168. Includes list of important Diesel ships in service and building, giving particulars of their machinery. Paper read before Institution of Civil Engineers.

D

DISKS

Spinning, Vibrations of. The Vibrations of a Spinning Disk, H. Lamb, and R. V. Southwell. Proc. Royal Soc., vol. 99, no. A 699, July 1, 1921, pp. 272–280. Treats of the transverse vibrations of a circular disk of uniform thickness rotating about its axis with constant angular velocity.

DRILLING MACHINES

Horizontal. Recent Machine Tool Developments—XX, Joseph Horner. Engineering, vol. 112, no. 2897, July 8, 1921, pp. 33–36, 20 figs. 13 on supp. plate. Horizontal boring and drilling machine constructed by Cunliffe & Groom, Ltd., Manchester, England.

Radial. A New Radial Drilling Machine. Eng. Production, vol. 3, no. 40, July 7, 1921, p. 19, 1 fig. Describes new machine manufactured by Kitchen & Wade, Halifax, of low-base type, baseplate of which is of deep section, well ribbed and planed both top and bottom.

DRILLS

Tap. Tap Drill Sizes, E. C. Peck and T. F. Githens. Am. Mach., vol. 55, no. 5, Aug. 4, 1921, pp. 194–196, 4 figs. Elements to be considered. What constitutes government standard. Minimum and maximum limits for tap holes. Determining ideal drill size.

DROP FORGING

Cost Analysis. Analysis of Costs of Drop-Forging, R. T. Herdegen. Iron Age, vol. 108, no. 6, Aug. 11, 1921, pp. 325–326. Comparison of steam and board drop hammers. Rate of production studied as well as costs. Dividing line established between types.

Economical Shop Practice. Cutting Costs in a Drop Forge Shop, F. L. Prentiss. Iron Age, vol. 108, no. 7, Aug. 18, 1921, pp. 385–388, 6 figs. Trolley system used for handling work between hammers and furnaces. Features include water-reclaiming plant.

Plants. Modern Drop Forge Plant Completed, E. C. Cook. Forging & Heat Treating, vol. 7, no. 7, July 1921, pp. 364–369, 14 figs. The Pittsburgh Knife & Forge Co's. new plant at Coraopolis, Pa., is said to incorporate latest ideas in design for production of special parts. Complete plant layout is given.

DUST

Dust-Removal Plants. Modern Dust-Removal Plants (Neuerungen auf dem Gebiete der Entstaubung und Staubförderung), H. Klug. Fördertechnik u. Frachtverkehr, vol. 14, nos. 4 and 5, Feb. 18 and Mar. 4, 1921, pp. 43–46 and 60–62, 7 figs. Describes the Delbag dust-removal and air filter plant in the grinding and polishing works of the Fritz Heckert Glass Factory, Petersdorf.

E

EDUCATION, ENGINEERING

Gas Course. University of Michigan Gas Course, J. Gerald Ames. Gas Age, vol. 48, no. 2, July 25, 1921, pp. 45–49. Course established under Prof. A. H. White and under patronage of Mich. Gas Assn.

Prerequisites to Technical Study. Engineering Courses Should Be of Professional Grade, Wm. H. Burr. Eng. News-Rec., vol. 87, no. 2, July 14, 1921, pp. 65–66. Argues that technical study should be preceded by three years of general college work. (Abstract.) Paper read before Soc. for Promotion of Eng. Education.

ELASTICITY

Elastic Limit. The Elastic Limit, William E. Dalby. Engineering, vol. 112, no. 2897, July 8, 1921, p. 81, 3 figs. Points out that limit of proportionality of material is not a fixed point, but varies with heat treatment and vanishes with overstrain. Paper read before Instn. Civ. Engrs.

ELECTRIC DRIVE

Blooming Mill. Electric Drive for Blooming Mill Service, B. M. Jones. Power Plant Eng., vol. 25, no. 14, July 15, 1921, pp. 721–724, 6 figs. Bethlehem Steel Co. discards steam engine; results gratifying.

Paper Mills. Electric Driving in the Paper Mill, on Heat-Economy Lines, A. B. Mallinson. Jl. Instn. Elec. Engrs., vol. 59, no. 301, May 1921, pp. 538–553 and Discussion pp. 553–563, 10 figs. Discusses uses of steam in paper manufacture, classes of machinery driven, including suitable electrical gear, driving of the variable-speed end of paper machine. Table of machines converted to electrical working in the United Kingdom.

ELECTRIC FURNACES

Heat-Treating. Automatic Heat-Treating Furnaces, Gilbert L. Lachter. Iron Age, vol. 107, no. 26, June 30, 1921, pp. 1754–1755, 4 figs. Charging, treating, quenching and drawing performed and governed by automatic devices easily set.

Electric Furnace Treatment of Dies and Forgings, E. F. Collins. Forging & Heat Treating, vol. 7, no. 7, July 1921, pp. 387–392, 7 figs. Describes different types of furnaces. Paper presented at Am. Drop Forge Convention, Chicago.

Induction. New Type of Induction Electric Furnace. Iron Age, vol. 108, no. 6, Aug. 11, 1921, pp. 344–346, 6 figs. Primary winding above bath. Experience with 2-ton unit. For refining molten metal and serving as holding reservoir and melting ferromanganese.

Laboratory Types. Electric Furnace—I, Ezer Griffiths. Beama, vol. 9, no. 1, July 1921, pp. 12–18, 4 figs. Laboratory types. Notes on resistor, iridium tube, zirconia, and tube furnaces.

Resistance Type. Electric Furnace Heat Treatment, E. F. Collins. Iron Age, vol. 108, no. 5, Aug. 4, 1921, pp. 266–267 and (discussion) pp. 267–268. Dies and forgings said to be well handled in metallic resistor furnaces. Uniformity of product a big feature. (Abstract.) Paper read before Am. Drop Forge Assn.

Steel. Electric Furnaces for Making Steel, Alfred Stansfield. Blast Furnace and Steel Plant, vol. 9, nos. 7 and 8, July and Aug. 1921, pp. 424–425, 2 figs., and 488–489, 2 figs. General features and advantages of Keller furnace and Stobie furnace. Classification of electric steel-making furnaces. Advantages of electrode hearth arc furnaces having single arc and one movable electrode.

ELECTRIC HEATERS

Immersion Type. Application and Use of Immersion Electric Heaters, John M. Striat. Elec. Rev., (Chicago), vol. 79, no. 5, July 30, 1921, pp. 161–163, 4 figs. Particulars of installing, size and capacity, precautions to be observed.

ELECTRIC LOCOMOTIVES

Industrial. Industrial Electric Locomotives. Engineer, vol. 131, no. 3417, June 24, 1921, pp. 666–667, 3 figs. Types built by English Electric Co.

Mechanical Advantages. Mechanical Advantages of Electric Locomotives Compared with Steam, Vincent L. Raven. Engineering, vol. 112, no. 2899, July 22, 1921, pp. 164–165. Summarizes mechanical disadvantages of steam locomotive, and discusses fuel economy made possible by use of electric locomotives, together with maintenance costs, and various designs of electric locomotives depending upon method adopted to transmit power from motors to driving axles. Paper read before Instn. Civ. Engrs.

Steam vs. Electric Shunting Locomotives. Tramway & Ry. Wld., vol. 50, no. 3, July 14, 1921, pp. 11–13, 3 figs. Describes the advantages of electric over steam locomotives.

Switching. B.T.H. Electric Shunting Locomotives. Elec. Rev. (Lond.), vol. 89, no. 2275, July 1, 1921, pp. 27–28, 2 figs. Details of a 10-ton and 22-ton shunting locomotive weighing 56 tons each and fitted with 90-hp. motors, which can start a train weighing 160 tons on a grade of 1 in 27 and haul it on grade 10 mi. per hr.

ELECTRIC PLANTS

Temperature Measurement. Measuring Temperatures in Electric Installations (La Mesure des Températures dans les Installations Electriques), M. Henry. L'Industrie Electrique, vol. 30, no. 698, July 25, 1921, pp. 265–270, 7 figs. Describes various thermometers and thermocouples and other indicators.

ELECTRIC POWER

Industrial Load, New York State. Industrial Load in the State of New York. Elec. World, vol. 78, no. 5, July 30, 1921, pp. 207–210, 3 figs. Amount of electrical energy used in New York State has increased over 100 per cent since 1914.

ELECTRIC WELDING

Oil Tanks. The Electric Welding of Oil Storage Tanks, William Schenstrom. Ry. Elec. Engr. vol. 12, no. 7, July 1921, pp. 267–271, 6 figs. Welded construction eliminates loss from leakage and it is estimated tanks will outlast riveted containers. (Abstract.) Paper presented before Am. Welding Soc.

Percussive. Electric Percussion Welding, (La Soudure Électrique Par Percussion), L'Industrie Electrique, vol. 30, no. 696, June 25, 1921, pp. 229–231. Applications and advantages of this process.

ELECTRIC WELDING, ARC

Advantages. Electric Arc Welding, Henry M. Sayers. Tramway & Ry. Wld., vol. 50, no. 3, July 14, 1921, pp. 25–29, 12 figs. Notes on its increased use, successes, difficulties and failures.

Cost Data. Notes on Electric Arc Welding. H. L. Unland. A.S.R.E. Jl., vol. 7, no. 6, May 1921, pp. 426–430 and (discussion) pp. 430–431. Gives cost figures for arc welding and a comparison between gas and electric equipment.

Heavy Sections. Welding of Heavy Sections by the Electric Arc. Can. Machy., vol. 26, no. 2, July 14, 1921, pp. 32–33 and 46, 2 figs. Instructions for preparing work to be welded. Welding of cast iron is classed under four heads. (Abstract.) Book entitled Electric Arc Cutting and Welding, published by Elec. Arc Cutting & Welding Co., Newark, N. J.

EMPLOYEES

Care of. The Human Machine in Industry, Walter J. Matherly. Am. Mach., vol. 55, no. 6, Aug. 11, 1921, pp. 226–227. Care of human machine as important as care of machines of metal. Length of working day. Periods of rest. Fuel.

EMPLOYMENT MANAGEMENT

Psychotechnical Tests. Psychotechnical Adaptability Tests and Their Use in Metallurgical Works (Die psychotechnische Eignungsprüfung und ihre Anwendung auf Hüttenbetriebe). Stahl u. Eisen, vol. 41, no. 24, June 16, 1921, pp. 822–827. Contributions by H. Hüttenhain, Heinrich Roser, and Hans Daiber. Report of the Machine Committee of the Assn. German Steel Works Engrs.

EXECUTIVES

Training. Coöperating to Educate a Community's Executives, H. C. Stevenson. Factory, vol. 27, no. 2, August 1921, pp. 182–187, 4 figs. Describes efforts of Rochester Industrial Management Council in this direction.

EXHAUST STEAM

Oil Removal from. Eliminating Cylinder Oil from Exhaust Steam, W. H. Wakeman. Power Plant Eng., vol. 25, no. 15, August 1, 1921, pp. 749–752, 8 figs. Discusses the essential features in a separator to give satisfactory results.

Utilization. Exhaust Steam; Its Employment for Power, Heating, Etc., Ernest Richard Dolby. Engineering, vol. 112, no. 2897, July 8, 1921, p. 74. Notes on better utilization of heat in steam. In author's opinion, most efficient utilization of thermal value in coal cannot be obtained until there are sets of public mains provided by community for public utility. Paper read before Instn. Civ. Engrs.

The Utilization of Exhaust steam in Turbines, Maurice Deacon. Engineering, vol. 112, no. 2899, July 22, 1921, pp. 165–166, 3 figs. Describes general arrangement of mixed-pressure turbine plant. Cost of generating electrical power by exhaust steam is very low due to fact that steam would otherwise be wasted. Paper read before Instn. Civ. Engrs.

EXTENSOMETERS

Calibration. An Extensometer Calibrating Device, R. L. Templin. Chem. & Met. Eng., vol. 25, no. 6, August 10, 1921, pp. 248–251, 5 figs. Describes various instruments and methods of operation.

EVAPORATORS

Multiplex Film. Multiple Effect Evaporation, Burton Dunglinson. Chem. & Metallurgical Eng., vol. 25, no. 3, July 20, 1921, pp. 110–115, 7 figs. Discussion of multiplex film evaporator as regards features of construction and operation. Comparison of multiplex with other types.

Soderlund-Boberg. Evaporation by Vapor Compression, Burton Dunglinson. Chem. & Met. Eng., vol. 25, no. 6, August 10, 1921, pp. 246–247, 2 figs. Describes the Soderlund-Boberg evaporator.

F

FACTORIES

Layout. Features of German Machine Tool Plant. Iron Age, vol. 108, no. 5, Aug. 4, 1921, pp. 256–258, 6 figs. Color of buildings considered. Prevailing winds aid in reducing dust and noise. Welfare of apprentices and workmen emphasized. Built by Fritz Werner Co., Marienfelde near Berlin.

The Layout of a Modern Machine-Tool Plant, Fred H. Colvin. Am. Mach., vol. 55, no. 5, Aug. 4, 1921, pp. 173–175, 6 figs. Layout of Foote-Burt shop. Receiving material and shipping finished machines. Crane and monorail transport. Overhead hot-water heating system.

FACTORY MANAGEMENT

[See INDUSTRIAL MANAGEMENT.]

FEEDWATER HEATERS

Locomotive. Feed Water Heater and Pump for Locomotives. Engineering, vol. 112, no. 2899, July 22, 1921, pp. 150–151, 8 figs. System adopted by G. & J. Weir, Ltd., Glasgow, is that of exhaust heating only, with a surface heater, a pump being employed to force the feed through heater and into boiler.

Types. Selection of Feed Water Heaters for Power Plants, Robert June. Elec. Rev. (Chicago), vol. 79, no. 3, July 16, 1921, pp. 81–84, 4 figs. Relative merits of open and closed heaters. Heated feedwater is said to reduce strains and increase boiler output.

FERROSILICON

Silicon Content. Effect of Silicon On the Property of Ferrosilicon (Influenza del silicio sulle propreita del ferrosilicio), G. Ongaro. Il Forno Elettrico, vol. 3, no. 5, May 15, 1921, pp. 63–66. Discusses various percentages of Si. Metallurgical effect of various silicon contents.

FIRE PREVENTION

Dust Explosions. Incandescent Lamps Used in Dust-Laden Atmosphere, D. J. Price & H. R. Brown. Elec. Rev., vol. 79, no. 5, July 30, 1921, pp. 165–166, 1 fig. Shows that they constitute a fire and dust-explosion hazard unless properly installed and adequately protected.

Explosions of Highly Inflammable Liquids. Stopping Fires in Highly Inflammable Liquids. Charles H. Meigs. Fire & Water Eng., vol. 70, no. 2, July 13, 1921, pp 58–59 and 64–65, 3 figs. Effective method of extinguishment. Application of foam system.

FLOUR MILLS

Rolls. The Manufacture of Chilled Iron Rolls. Am. Miller, vol. 49, no. 8, August 1, 1921, pp. 822–823, 10 figs. Processes employed in producing high grade rolls for flour milling.

FLOW OF WATER

Manning's vs. Kutter's Formula. Manning's Formula Better Than Kutter's. Eng. News-Rec., vol. 87, no. 3, July 21, 1921, p. 96, 2 figs. H. W. King suggests that an abbreviated form of Kutter's equation, eliminating the *s* or slope terms, will give far more consistent results, and that in his opinion Kutter's formula will give just as satisfactory results without the *s* terms.

Riveted Steel Pipes. Flow of Water Through Galvanized Spiral Riveted Steel Pipe, F. W. Greve. Eng. News-Rec., vol. 87, no. 4, July 28, 1921, pp. 159–160, 3 figs. Results of experiments performed in hydraulic laboratory of Purdue University to determine variation of friction loss with velocity for flow; variation in accuracy of four types of piezometer rings; and friction loss compared with that in cast-iron pipes for like conditions of diameter and velocity.

FOREMEN

Classes, Training Leaders for. Training Leaders for Foremanship Classes, D. J. MacDonald. Am. Mach., vol. 55, no. 7, Aug. 18, 1921, pp. 249–251. Fundamental factors involved in training leaders. Outstanding characteristics of typical foreman. Importance of follow-up work in organizing courses.

FORGING

Costs. Comparative Analysis of Forging Costs, R. T. Herdegen. Forging & Heat Treating, vol. 7, no. 7, July 1921, pp. 397–399. States that it costs more to operate a 1500-lb. steam drop hammer than to operate a 1600-lb. board hammer; and it is not desirable to install a steam drop smaller than 2500 lb.

Hand vs. Die Forging. Die versus Hand Forging (Wann ist Gesenkschmieden, wann Schmieden von Hand wirtschaftlicher?), Ferd. Klages. Betrieb, vol. 3, no. 17, May 25, 1921, pp. 519–521, 8 figs. Investigation of relative merits of hand and die forging, taking into consideration saving in time, wages and material. Discusses favorable effect of swaging on structure of material and possibility of setting up more accurate piece-rate wages.

Manipulators. Mechanical Manipulator for Heavy Forgings. Engineering, vol. 112, no. 2899, July 22, 1921, p. 151, 4 figs. partly on p. 154. Machines constructed by Alliance Machine Co., Alliance, Ohio.

FORGINGS

Ingot Sizes for. Cross-Sectional Dimensions of Steel Ingots for Forged Pieces (Ueber Querschnitts-Abmessungen von Stahlblöcken fur Schmiedestücke), F. Pacher. Stahl u. Eisen, vol. 41, no. 27, July 7, 1921, pp. 913–917 and (discussion) pp. 918–919. Deals with faults in forged pieces caused by selection of wrong dimensions of casting mold.

FOUNDATIONS

Bearing Value of Soils. The Bearing Power of Soils, Arthur L. Bell. Engineering, vol. 112, no. 2898, July 15, 1921, p. 132. Brief outline of progress in theories of earth pressure and bearing value of soils for foundations. Paper read before Instn. Civ. Engrs.

Concrete. Foundations, J. C. Hawkins. Power Plant Eng., vol. 25, no. 15, August 1, 1921, pp. 760–762, 5 figs. Templets, forms and process for mixing and placing concrete.

Pneumatic Caisson. Pneumatic Caisson Foundations for Tall Buildings, Frank W. Skinner. Compressed Air Magazine, vol. 26, no. 7, July 1921, pp. 10143–10148, 9 figs. Highly developed use of compressed air for building deep and difficult footings impossible to construct by any other method.

FOUNDRIES

Safety Provisions. Safety in Foundry Equipment, A. R. Bartlett. Mech. Wld., vol. 70, no. 1803, July 22, 1921, pp. 70–72. Discusses danger signs, foundry yard, foundry floor, ventilating and lighting, cranes, chains and slings, etc.

FRAMES

Rigid, Calculation of. Graphic Investigation of Rectangular Rigid Frames (Zeichnerische Untersuchung rechteckiger Steifrahmen), J. Polivka. Beton u. Eisen, vol. 20, no. 4–5, Mar. 7, 1921, pp. 57–60, 12 figs. Graphic calculating method for determination of the moments and normal forces in closed and fixed-in rigid frames.

FREIGHT HANDLING

Danube River. Mechanical Freight Loading and Unloading Plants on the Trans-shipment Docks of the First Danube Steam Navigation Co. (Die mechanische Güterumladung auf den Umschlagplätzen der Ersten Donau-Dampfschiffahrts-Gesellschaft), W. Hollitscher. Fördertechnik u. Frachtverkehr, vol. 14, nos. 2, 3, 4 and 5, Jan. 21, Feb. 4, 18 and Mar. 4, 1921, pp. 21–26, 34–38, 46–49 and 62–65, 15 figs. Described plants are distributed over a stretch of 4000 km. Notes on organization, application of principles of scientific management, etc. The technical and commercial organization of the department for loading plants of above-mentioned company is described in detail.

Mechanical. Mechanical Freight Handling on the New York Central Lines, William T. Gaynor, Transportation Wld., vol. 3, no. 5, July-August 1921, pp. 11–12, 1 fig. Shows the influence of local conditions on mechanical handling methods.

Unit Cost Data. Unit Cost Data Reduce Freight Train Expense, J. E. Hutchison. Ry. Age, vol. 71, no. 4, July 23, 1921, pp. 161–163, 1 fig. Prompt distribution of information aids in cutting wage charges per hundred ton miles. Shows form used in reporting wage cost of handling trains on St. Louis-San Francisco railway system.

FRICTION

Sliding and Rolling. The Theory of the Sliding and Rolling Resistance of Solid Bodies (Zur Theorie des Gleit- und Rollwiderstandes der festen Körper), Sigmund Fuchs. Physikalische Zeit., vol. 22, nos. 6 and 7, Mar. 15 and Apr. 1, 1921, pp. 173–177 and 213–218. Explains so-called dry sliding friction of solid bodies through the hydrodynamic friction of air stratum between the bodies; and the friction phenomena between specially cleaned surfaces in a vacuum. The rolling resistance of elastic bodies under assumption of an incomplete elasticity is determined. Discusses cause of so-called slip with rolling of the elastic body; and influence of distribution of mass of rolling body on size of moment of resistance.

Colloidal. Colloidal Fuel. Pac. Mar. Rev., vol. 18, no. 7, July 1921, pp. 394–396, 1 fig. Article compiled from interviews with and printed material submitted by Linden W. Bates, who controls basic patents covering process for colloidalization of oil and fuels. Describes small colloidalizing plant, and points out principal advantages of colloidal fuel.

Colloidal Fuel Applied to Bar-Heating Furnaces Engineering, vol. 112, no. 2898, July 15, 1921, pp. 124–125, 5 figs. Report by J. C. Marble on trials made on rod-heating furnace at Swansea Works of Steel Co. of Canada. Attention is drawn to fact that fuel, though old, showed no signs of sedimentation, and that owing to its specific gravity fire risk was capable of being greatly reduced as compared with oil.

Future Problems. Fuel Problems of the Future, George T. Beilby. Gas Jl., vol. 154, no. 3033, June 29, 1921, pp. 737–743; also Gas World, vol. 75, no. 1928, July 2, 1921, pp. 6–8 and 9–10; also Engineering, vol. 112, no. 2896, July 1, 1921, pp. 26–30. Writer points out that coal is likely to remain for a long time the world's chief source of fuel, and its more efficient use may be secured by more careful sorting and preparation of mines; improvement of boiler firing; and sorting out of its combustible constituents into fuels of higher availability or convenience by preliminary carbonization at either high or low temperatures. James Forrest lecture before Instn. Civ. Engrs.

Industrial Heating. Selection of Fuel for Industrial Heating. Chem. & Metallurgical Eng., vol. 25, no. 3, July 20, 1921, pp. 116–118, 1 fig. Includes chart showing comparative fuel costs, and table giving characteristics of various industrial gases. (Abstract.) Pamphlet copyrighted by W. S. Rockwell Co.

Research Station. The Fuel Research Station at East Greenwich. Gas World, vol. 75, no. 1928, July 2, 1921, pp. 3–4. Notes on work being carried out and significance in connection with gas and fuel problems.

Substitutes for Coal. Alternatives to Coal for Power Production, Percy E. Rycroft. Elecn., vol. 86, no. 2249, June 24, 1921, pp. 783–787, 10 figs. Discusses value of refuse destructors, oil, coke, colloidal fuel, lignite, etc., as substitutes.

Utilization. University of Public Works, Commission on Utilization of Fuels (Ministère des Travaux Publics, Commission d'Utilisation du Combustible), Revue de l'Industrie Minérale, no. 11, June 1, 1921, pp. 423–426. Continuation of report. (To be continued.)

[See also CARBOCOAL; COAL; COKE; COKE BREEZE; OIL FUEL; PEAT; PULVERIZED COAL; TAR OILS.]

FURNACES, BOILER

Flue-Dust Abatement. The Formation and Abatement of Flue Dust (Flugaschenbildung und Flugaschenbeseitigung), F. Kaiser. Zeit. des Bayerischen Revisions-Vereins, vol. 25, no. 12, June 30, 1921, pp. 106–108, 2 figs. Discusses various means for prevention and removal of flue dust.

FURNACES, BRASS-MELTING

Natural-Draft Type. A Type of Natural Draft Melting Furnace—1, Charles Vickers. Brass World, vol. 17, no. 7, July 1921, pp. 197–201, 4 figs. Particulars of construction, types of furnaces and dimensions, location and building of furnaces.

FURNACES, HEATING

Ingot. The Siemens Regenerative Gas Ingot-Heating Furnace with Divided Flame (Der Siemens-Regenerativ-Gas-Stossofen mit Flammenteilung), Arthur Sprenger. Stahl u. Eisen, vol. 41, no. 22, June 2, 1921, pp. 749–753, 6 figs. Describes regenerative furnace with divided flame and vertical U-shaped flame arch, and points out its adaptability to any given conditions and construction types. It is claimed that the new furnace type will greatly contribute to utilization of low-grade gases with simultaneous recovery of by-products.

FURNACES, HEAT-TREATING

Die Blocks, for. Furnaces for Heat Treatment of Die Blocks, S. Trood. Forging & Heat Treating, vol. 7, no. 7, July 1921, pp. 393–397, 7 figs. Discusses proper proportioning and mixing of fuel and air, temperature of ignition, time element, velocity and space required by products of combustion and recirculation.

Molydenum Steel Parts. Special Heat-Treating Furnaces for Molydenum Steel Parts. Automotive Manufacturer, vol. 63, no. 4, July 1921, pp. 19–21, 4 figs. Description of unusual automatic furnaces installed and principle of operation.

FUSION WELDING

Possibilities. The Possibilities of Fusion Welding, A. S. Kinsey. Iron Age, vol. 108, no. 6, Aug. 11, 1921, pp. 337–338. Conditions for this type of weld. Control of welders. Test of welds. Success with alloy steels. (Abstract.) Address before Cleveland Section Am. Welding Soc.

G

GAGES

Economic Selection. Suggestions for an Economic Selection of Types of Gages from the Systems of Standard Holes and Standard Shafts (Richtlinien für eine wirtschaftliche Auswahl der Lehrenarten aus den Systemen der Einheitsbohrung und der Einheitswelle), K. Gottwein. Betrieb, vol. 3, no. 18, June 10, 1921, pp. 266–273, 10 figs. Author's recommendation is approved by sub-committee of German Industry Committee on Standards (NDI), and is thought to be especially adapted to mixed production, for giving the different firms a basis for selection of the necessary gages for all cases in which the use of unit systems is not required.

Hoke. Hoke Gages, Earle Buckingham. Army Ordnance, vol. 2, no. 1, July-August 1921, pp. 36–38, 4 figs. Discusses the importance of accurate gages in the production of munitions.

Industrial. Study of Industrial Gages at International Bur. of Weights and Measures. (L'Etude des Calibres Industriels au Bureau international des Poids et Mesures). Le Génie Civil, vol. 78, no. 24, June 11, 1921, pp. 500–503, 9 figs. Standard Gages of Johansson type. Gaging by light-interference method. (Concluded.)

GAS ENGINES

British Type. Machinery at the Royal Agricultural Show. Engineering, vol. 112, no. 2896, July 1, 1921, pp. 7–10, 6 figs. Details of suction gas producer for wood refuse 50-hp. gas engine constructed by Davey, Paxman & Co., Ltd., Colchester.

GAS PRODUCERS

Operation. Graphic Investigations in Produce Operation (Graphische Untersuchungen im Generatorbetrieb), W. Claus and L. Neuszel. Zeit. des Vereines deutscher Ingenieure, vol. 65, no. 29, July 16, 1921, pp. 769–773, 8 figs. Discusses Ostwald's method for the graphic presentation of performance in producer and describes further use of this method for simple determination of the special properties of producer gases. Exemplifies use of derived tables and recommends a standard international terminology for producer gases.

GASES

Throttling Effect. The Throttling Effect and Equation of Condition (Drosselwirkung und Zustandgleichung), K. Schreber. Zeit. fur komprimierte u. flüssige Gase, vol. 21, nos. 1, 2, 3, 4, 5 and 6, 1920, pp. 1–7, 17–21, 29–33, 44–45, 53–56 and 65–68, 4 figs. Presents equation which can be used to calculate throttling effect when equation of condition is known, or to derive an equation of condition when throttling effect is known.

GASOLINE

Casinghead Gas. Casinghead Gas. Oil Field Eng., vol. 23, no. 7, July 1921, pp. 70–72. Gives particular of the production of gasoline from casinghead gas.

Engine, Specifications for. Problems Involved in Developing Engine Gasoline Specifications, E. W. Dean. Jl. Soc. Automotive Engrs., vol. 9, no. 2, August 1921, pp. 131–132. Gives general properties of satisfactory engine gasoline and specification limits.

GEAR CUTTING

Hobbing Worms. A Novel Method of Hobbing Worms. Automotive Ind., vol. 45, no. 4, July 28, 1921, pp. 171–172, 3 figs. Uses a helicoidal cutter.

Methods. Recent Gear-Cutting Practice—IX. Mech. Wld., vol. 70, no. 1803, July 22, 1921, pp. 58–59, 14 figs. Discusses small spur gears, including internal, and ratchets. (To be continued.)

Multiple Shapers. Cuts Teeth of a Gear at One Operation. Iron Age, vol. 108, no. 4, July 28, 1921, pp. 197–200, 7 figs. Stevenson multiple shaper, how it operates and its field.

Racks. A New Rack Cutting Attachment. Eng. Prod., vol. 3, no. 44, August 4, 1921, pp. 100–101, 4 figs. Details of a useful device for use on milling machines.

GEARS

Comparator, Gear-Tooth. The Sykes Gear Tooth Comparator. Machy. (Lond.), vol. 18, no. 459, July 14, 1921, pp. 454–455, 3 figs. For comparing and measuring thickness of gear teeth.

The Sykes Gear-Tooth Comparator. Engineering, vol. 112, no. 2898, July 15, 1921, p. 103, 3 figs. Instrument consists of short bar fitted with one fixed and one sliding jaw, arranged with needle of a dial indicator between the two, and is used for comparison of thickness of gear teeth and uniformity of pitch. Other uses.

Teeth, Strengthened. Stengthened Gear Teeth. Eng. Production, vol. 3, no. 41, July 14, 1921, pp. 28–30, 8 figs. Notes on principles applied. Includes summary of various formulas for long addendum gear teeth.

Testing Machine for Teeth. The Odontometer for Testing Gear Teeth, Earle Buckingham. Machy. (Lond.), vol. 18, no. 458, July 7, 1921, pp. 412–413, 6 figs. Describes instrument for testing accuracy or uniformity of gear-tooth profiles and spacings of teeth in production work, developed by Pratt & Whitney Co.

GRAIN ELEVATORS

Oakland, Cal. Bulk Handling of Grain in California, Charles W. Geiger. Ry. Rev., vol. 69, no. 7, August 13, 1921, pp. 205–208, 5 figs. Particulars of a new 1¼-million-bushel elevator at Oakland and others, carloading equipment for bulk grain, etc.

GRAIN HANDLING

Unloader. Electrically Operated Grain Car Unloaders, R. T. Kintzing. Elec. Jl., vol. 18, no. 7, July 1921, pp. 301–304, 7 figs. Describes car dumpers of Northern Central grain elevator of P.R.R., four of which side by side, with operating crew of 18 men, can unload 400 cars daily, each car containing from 1200 to 2000 bushels of grain.

GRINDING

Automobile Parts. Grinding the Automotiv ni Industry—1, P. M. Heldt. Automotive Ind., vol. 45, no. 6, August 11, 1921, pp. 265–269, 11 figs. Describes the various kinds of grinding wheels, their selection, cutting speeds, balancing, truing, etc.

Data. Recent Data on Grinding Room Production. Abrasive Industry, vol. 2, no. 7, July 1921, p. 241. Data on grinding valves, steel pins, square shafts and valve stems.

Modern Methods. The Economy of Modern Grinding Methods, Harlowe Hardinge. Chem. & Met. Eng., vol. 25, no. 6, August 10, 1921, pp. 229–232. Considers high cost of obsolete grinding plant, classification of grinding operations, etc.

GUNS

16-In. 50-Caliber. 16-Inch 50-Caliber Gun and Barbette Carriage, G. M. Barnes. Army Ordnance, vol. 2, no. 1, July-August 1921, pp. 15–20, 9 figs. Gives particulars of gun and projectiles.

H

HANDLING MATERIALS

Loading Cars from Boats. Transshipping Bulk Freight (Umladevorrichtungen), Otto Kummel. Fördertechnik u. Frachtverkehr, vol. 14, no. 4, Feb. 18, 1921, pp. 49–50, 2 figs. Notes on transshipping gears for bulk freight (coal, ore, gravel, etc.), with utilization of differences in altitude of land in ship-canal locks.

Pressed-Steel Plant. Routing of Material Feature of Plant, F. L. Prentiss. Iron Age, vol. 107, no. 26, June 30, 1921, pp. 1741–1745, 5 figs. Youngstown Pressed Steel Co. introduces tunnels under new shops to avoid congestion of traffic. Other operating economies.

Ship Cargoes. Speed and Economy Follow Mechanical Handling of Ship Cargoes, Roy S. MacElwee. Transportation Wld., vol. 3, no. 5, July-August 1921, pp. 24–27. Discusses special handling equipment, demountable bodies as an economic factor, tonnage, etc.

HEAT

Mechanical Equivalent. A New Method of Determining the Mechanical Equivalent of Heat, T. H. Laby & J. K. Roberts. Proc. Royal Soc. of Victoria, vol. 32, Part II, September 1920, pp. 148–155, 8 figs. Describes design and operation of a new apparatus for this purpose in which a copper cylinder is heated by a rotating magnetic field.

HEAT TRANSMISSION

Experiments. A New Thermal Testing Plate for Conduction and Surface Transmission, F. C. Houghten & A. J. Wood. Jl. Am. Soc. Heat. & Vent. Engrs., vol. 27, no. 5, July 1921, pp. 529–542 and (discussion) pp. 614, 12 figs. Particulars of investigation and results of experiments.

Liquids and Gases. Heat Transmission in Liquids and Gases as Function of Velocity (Der Wärmeübergang bei Flussigkeiten und Gasen als Funktion der Geschwindigkeit), H. Preussler. Stahl u. Eisen, vol. 41, no. 24, June 16, 1921, pp. 827–830. Investigation of influence of velocity of gas and liquids on heat transmission, demonstrating advisability of introducing heat capacity in place of velocity. Formulas for heat transmission through conduction and radiation are tested with regard to their feasibility for steam-boiler and heat-storage calculation.

Problems. A Survey of Heat Transmission Problems, W. M. Selvey. Elecn., vol. 87, no. 2250, July 1, 1921, pp. 11–12. Review of trilogy of books by R. Royds entitled, Measurement of Steady and Fluctuating Temperatures; Heat Transmission by Radiation, Conduction and Convection; and Heat Transmission in Boilers, Condensers and Evaporators.

HEATING AND VENTILATION

Westinghouse Works, East Pittsburgh. Heating Equipment for a Large Industrial Plant, O. H. Bathgate. Heating & Ventilating Mag., vol. 18, no. 7, July 1921, pp. 29–32, 4 figs. Method followed in East Pittsburgh Works of Westinghouse Elec. & Mfg. Co.

HEATING, FACTORY

Requirements. Requirements for Industrial Heating, Harold Fulwider. Elec. World, vol. 78, no. 4, July 23, 1921, pp. 167–169, 2 figs. How to determine power required for ovens and energy consumption per unit of product. Typical calculations for japanning and core-baking ovens. Selection of ventilating equipment.

HEATING, HOT-WATER

Gravity System. Advanced Ideas Applied in Design of a Gravity Water Heating System, William F Devendorf. Heat & Vent. Mag., vol. 18, no. 8, August 1921, pp. 25–28, 5 figs. Describes an installation that circulates hot water through supply mains at all times.

HELICOPTERS

New Types. Recent Helicopters (Nouveaux Hélicoptères), Jean-Abel Lefranc. La Nature, no. 2466, July 9, 1921, pp. 20–25, 9 figs. Describes the Damblanc-Lacoin, Oehmichen, Petroczy-Karman, Lamé and Pescara.

HOBBING MACHINES

Hobbing Worms, New Method of. Gould & Eberhardt Method of Hobbing Worms. Am. Mach., vol. 55, no. 4, July 28, 1921, pp. 141–142, 3 figs. Worms cut with hob having a broaching action. Short hob permits cutting worms having shoulders at both ends.

Theory and Practice. Hobs and Hobbing, T. A. Stoddart. Eng. Prod., vol. 3, no. 44, August 4, 1921, pp. 102–104, 4 figs. Theory and practice of modern machines.

HOISTS

Mine. The Graphical Dynamics of a Winding Engine—III, Charles D. Mottram. Colliery Guardian, vol. 122, no. 3159, July 15, 1921, pp. 170–171, 5 figs. Discusses the question of friction between lubricated surfaces. (To be continued.)

HOUSES, CONCRETE

England. Concrete House Building. Concrete & Constructional Eng., vol. 16, no. 7, July 1921, pp. 425–431, 10 figs. Housing scheme at Southport, England.

HOWITZERS

75-mm. Pack. 75-mm. Pack Howitzer vs. 2.95-inch V. M. Mountain Gun, O. L. Beardsley. Army Ordnance, vol. 2, no. 1, July-August, 1921, pp. 38–44, 11 figs. Table of characteristics.

HYDRAULIC TURBINES

Development. Recent Development of Water Turbines (Die neuere Entwicklung der Wasserturbinen), Dieter Thoma. Zeit. des Vereines deutscher Ingenieure, vol. 65, no. 26, June 25, 1921, pp. 679–686, 21 figs. Modern Francis turbines; new types of draft tubes and their influence on motion of water in rotor; limited sphere of present turbine theory; useful scope of Kaplan turbine; the Moody turbine; vertical single-wheel turbines; high-pressure Francis turbines with vertical shaft; transformer installations; success of Bauersfeld's analytical turbine theory.

HYDROAEROPLANES

Caproni Giant. The Caproni Giant Hydroplane (L'hydravion triplan geant Caproni). Le Génie Civil, vol. 79, no. 2, July 9, 1921, pp. 39–40, 5 figs. Particulars of dimensions and tests.

HYDROELECTRIC PLANTS

California. Caribou Power Plant Completed, Charles W. Geiger. Power Plant Eng., vol. 25, no. 14, July 15, 1921, pp. 693–702, 17 figs. Details of power-transmission system, hydraulic equipment, power and efficiency guarantees, etc.

Kern River Plant Number Three of Southern California Edison Company Serves a Dual Purpose. Elec. Rec., vol. 30, no. 1, July 1921, pp. 12–15, 6 figs. Description of concrete dams, generator, and other equipment.

Semi-Automatic Operation Economical in Small Hydro Stations, E. R. Stauffacher & G. Clingwald, Elec. World, vol. 78, no. 5, July 30, 1921, pp. 213–216, 6 figs. Southern California Edison Company plant saves cost of extra equipment in seven months.

India. Hydro-Electric Supply in Bombay, India. Managing Engr., vol. 8, no. 3, July 1921, pp. 53–58, 8 figs. Principal features of the Tata Hydro-Electric system. (To be continued.)

Norway. The Hydroelectric Plants on Glomfjord in Norway (Die Wasserkraftwerke am Rjukanfos und am Glomfjord in Norwegen), Gg. v. Troeltsch. Zeit. des Vereines deutscher Ingenieure, vol. 65, no. 27, July 2, 1921, pp. 707–712, 20 figs. Location of plant on the Glomfjord in the extreme north. Water supply and equalization in lakes, galleries and pipe lines; machine house; cost of installation and price of current; turbines of 25,000 and 27,500 hp. respectively with 442 m. head; double regulation with needle nozzle and deflector.

Sweden. Trollhättan Hydroelectric Plant (Installations Hydro-électriques de Trollhättan), A. Tétrel. L'Electricien, vol. 52, no. 1278, June 15, 1921, pp. 265–271, 7 figs. Describes equipment, including d.c. and a.c. apparatus, insulation, etc., also substations.

Switzerland. Large Modern Hydroelectric Plants in Switzerland (Grandi Impianti Idroelettrici Moderni in Svizzera), Giovanni Rodio. L'Industria, vol. 35, no. 12, June 30, 1921, pp. 272–277, 17 figs. Detailed description of the Ritom plant, including dams, water supply, Pelton wheels, turbogenerators, transformers. (To be continued.)

The Construction of the Oberhasle Hydroelectric Plants According to the Projects of the Bernese Power Works Corp. (Die Bauten für die Kraftwerke Oberhasle gemäss den Projekten der B.K.W.). Schweizerische Bauzeitung, vol. 78, nos. 1 and 2, July 2 and 9, 1921, pp. 1–6 and 22–24, 15 figs. Account of project developed by G. Narutowics. Notes on water supply and available energy; building installations and transportation arrangements; water storage plants; the power stations Guttannen and Innertkirchen; costs of installation and price of energy.

The Hydroelectric Plant of Fully (Switzerland) [Die Wasserkraftanlage von Fully (Schweiz)], H. Fernau. Zeit. des Oesterr. Ingenieur- u. Architekten-Vereines, vol. 73, no. 24–25, June 24, 1921, pp. 163–166, 5 figs. Describes plant with total head of 1654 m., with special details of a pressure pipe line laid underground without any masonry support or anchorage. Operating experiences since 1914, when plant was completed.

HYDROGEN

Commercial Production. Commercial Production of Hydrogen Gas For Aeronautics (Procédés de Fabrication Industrielle de l'Hydrogène Aerostatique, Capt. Verneuil. L'Aéronautique, vol. 3, no. 25, June 1921, pp. 232–239, 4 figs. A review of existing methods, including the Hembert and Henry and the Badische Anilin.

I

IGNITION

Magnets. Magnetos for Ignition Purposes in Internal Combustion Engines, E. A. Watson. Jl. Instn. Elec. Engrs., vol. 59, no. 301, May 1921, pp. 445–466, Discussions pp. 467–490, 26 figs. Discusses conditions to be fulfilled by ignition magnetos on internal combustion engines and deals with the principles of operation of a magneto.

IMPACT TESTING

Suggestions. Impact Tests and Allowances, Harry John Fereday. Engineering, vol. 112, no. 2897, July 8, 1921, p. 80. Suggestions for conducting future tests in order to obtain, if possible, new formula for impact effect. Paper read before Instn. Civ. Engrs.

INDUSTRIAL MANAGEMENT

Cost Reduction. Reducing Manufacturing Costs by Studying Power Demand, R. S. Lowry. Elec. Wld., vol. 78, no. 6, August 6, 1921, pp. 257–258. Draws attention to inefficient operating conditions and causes of unnecessary expenditure.

Efficiency Control. Controlling Efficiency in the Clay Plant, Arthur H. Kaeppel. Brick & Clay Rec., vol. 59, no. 3, August 9, 1921, pp. 188–191, 3 figs. Discusses factory efficiency reports and production charts.

Factory Managers. The Duties of a Modern Factory Manager (Vilka krav böra ställas pa en modern arbetsledare?), Oliof Kärnekull. Teknisk Tidskrift, vol. 51, no. 19, May 14, 1921, pp. 221–226, 3 figs. Duties of a manager with regard to carrying out and standardization of production methods, selection of personnel with aid of psychology, etc. Loss of time in industrial plants is said to average 30 per cent of working time, half of which is unavoidable loss. This, it is claimed, can be considerably reduced by suitable working plans. In one case it was reduced in four months from 70 to 10 per cent.

Factory Statistics. Factory Statistics (Betriebsstatistik), Rudolf Reischle. Zeit. des Bayerischen Revisions-Vereins, vol. 25, nos. 10 and 11, May 31 and June 15, 1921, pp. 81–84 and 94–95, 3 figs. Deals with purpose and character, fundamental principles, carrying out and utilization of factory statistics; bookkeeping and net cost accounting; commercial bases for calculation of general operating costs.

Follow-Up System. Follow-Up System for the Drawing Office. Machy. (Lond.), vol. 18, no. 457, June 30, 1921, pp. 385–388, 6 figs. System for recording status and daily progress of work during process of manufacture.

Inspection. An Inspection and Progress System, E. A. Allcutt. Eng. & Indus. Management, vol. 6, no. 3, July 21, 1921, pp. 58–61 and 64. Explains the three main objects of successful management; good work, rapid work, economical work.

Instruction Sheets. Proposals for New Factory Instruction Sheets (Entwürfe neuer Betriebsblätter). Betrieb, vol. 3, no. 19, June 25, 1921, p. 136. Proposal of Works Dept. of German Federation of Technical and Scientific Societies for care and operation of lifting magnets.

Proposals for New Factory Instruction Sheets (Entwürfe neuer Betriebsblätter). Betrieb, vol. 3, no. 17, May 25, 1921, pp. 126–128. Proposal of Works Dept. of German Federation of Technical and Scientific Societies for care of ball bearings; measures for prevention of fire; and care of gear drive.

Motion Study. Scientific Management and Motion Study, F. James Butterworth. Royal Engrs. Jl., vol. 34, no. 2, August 1921, pp. 59–70, 7 figs. Discusses the work of Taylor and Gilbreth.

Output, Measurement of. The Measure of Output in Engineering, J. E. Powell. Mech. Wld., vol. 70, no. 1803, July 22, 1921, pp. 67. Discusses formulating the measure and responsibilities of management. (Abstract paper read before Inst. Ind. Admin.)

Overhead Costs. Cutting Overhead Cost Instead of Wages, Don. F. Kennedy. Iron Age, vol. 108, no. 2, July 14, 1921, pp. 79–81. Large Detroit automobile company paid war-time wages, ran half time and in same period made profits.

Purchasing System. What is a Comprehensive Purchasing System? Wilfred G. Asble. Can. Machy., vol. 26, no. 2, July 14, 1921, pp. 27–29, 9 figs. Suggestions for organizing effective system. Illustrations of form cards suitable for purchasing department.

Small Shop. Organization and Management of the Small Shop—I, II and III, Elmer W. Leach. Am. Mach., vol. 55, nos. 3, 5 and 7, July 21, Aug. 4 and 18, 1921, pp. 81–84, 190–193 and 262–266. July 21: How one small shop started and won battle against odds. Aug. 4: How to analyze manufacturing and marketing problems. Aug. 18: Methods of market analysis; different ways of reaching ultimate consumer; importance of establishing definite sales policy.

Storeroom Methods. Six Ways to Simplify Stockroom Routine, V. C. Kreuter. Factory, vol. 27, no. 2, August 1921, pp. 192–194, 5 figs. Shows how, through changes in stockroom routine, difficulties in routing, production, cost-keeping and inventory work may be adjusted.

Stores Keeping. Continuous Stores Keeping Cuts Investment. Iron Age, vol. 108, no. 5, Aug. 4, 1921, pp. 253–254, 2 figs. System checks and almost automatic control of ordering materials economizes in space required and in amount carried.

Toolroom Organization. Organization of the Tool Room, G. W. Tripp. Eng. & Indus. Management, vol. 6, no. 1, July 7, 1921, pp. 2–5, 3 figs. Outlines method of organizing tool room. Notes on arrangement of tool store, manufacture of jigs, grouping of cards and planning of work.

[See also TIME STUDY.]

INDUSTRIAL RELATIONS

Justice in. The Way Out in Industrial Relations, John Calder. Iron Age, vol. 107, no. 26, June 30, 1921, pp. 1766–1767. How shall management, labor and public secure justice? What underlies movement for a conference footing in individual companies. (Abstract.) Address before Iowa Mfrs. Assn.

INTERNAL-COMBUSTION ENGINES

Cast Iron, Use of. Cast Iron in the Construction of Internal Combustion Engines. Eng. & Indus. Management, vol. 5, no. 26, June 30, 1921, p. 736. Describes effect of increases of temperature on gray cast iron employed in construction of automobile cylinders and pistons.

Electric Starters. Electric Starters for Explosion Engines (Sur l'installation des demarreurs electriques pour moteurs a explosions), M. Digeion. Révue Générale de l'Électricité, vol. 10, no. 3, July 16, 1921, pp. 103–106, 4 figs. Considers conditions necessary, power absorbed, coupling, etc.

Influence of Fuels. The Influence of Various Fuels on the Performance of Internal Combustion Engines—VI, H. R. Ricardo. Automobile Engr., vol. 11, no. 152, July 1921, pp. 242–247, 6 figs. Experimental investigation into their behavior.

Installation. Practical Notes on the Installation and Running of Petrol, Petrol-Paraffin, and Semi-Diesel Engines, D. P. Lamb. Mech. Wld., vol. 70, no. 1803, July 22, 1921, pp. 72–73. Considers shafting, motor-seating, stern tube, fuel tanks, etc. (To be continued.)

Large Cylinders. Internal-Combustion Engines with Large Cylinders, James McKechnie. Engineering, vol. 112, no. 2898, July 15, 1921, pp. 132–134, 5 figs. Includes indicator cards and summaries of some of the trials of engines referred to, and also of Vickers' Narragansett type commercial marine engine with 24½-in. cylinder. Paper read before Instn. Civ. Engrs.

Types. The Internal-Combustion Engine. Steamship, vol. 33, no. 386, August 1921, pp. 49–53, 14 figs. Description of the two-stroke-cycle, four-stroke-cycle and semi-Diesel engines.

[See also AEROPLANE ENGINES; AUTOMOBILE ENGINES; DIESEL ENGINES; GAS ENGINES; OIL ENGINES; SEMI-DIESEL ENGINES.]

IRON

Corrosion. A Colloid Theory of the Corrosion and Passivity of Iron, and of the Oxidation of Ferrus Salts, John Albert Newton Friend. Jl. Chem. Soc., vol. 119–120, no. 704, June 1921, pp. 932–949, 2 figs. Author directs attention to a few important observations which cannot be explained by any known theory, and suggests new theory which appears to account for facts in reasonable manner.

A New Theory of the Corrosion of Iron, J. Newton Friend. Am. Electrochemical Soc. 40th Gen. Meeting 1921, advance paper, June 4, 1921, 13 pp., 9 figs. Writer puts forward auto-colloidal catalytic theory which postulates corrosion as starting by formation of colloidal ferrous hydroxide, which latter is alternately reduced by contact with iron and oxidized by contact with air, thus continuing corrosion and production of rust.

Corrosion of Iron and Its Prevention by Degassing Feedwater (Les Corrosions du Fer et Leur Suppression Par le Dégazage de l'Eau), G. Paris. Chimi & Industrie, vol. 6, no. 1, July 1921, pp. 11–32, 33 figs. Discusses theories of corrosion, effect of bodies dissolved in water, action of electric current, degasification and apparatus used.

Electrodeposition. Researches on the Electrodeposition of Iron, W. E. Hughes. Am. Electrochemical Soc. 40th Gen. Meeting 1921, advance paper, Apr. 25, 1921, pp. 15–33. Notes on electrodeposition of iron from sulphate, chloride, and sulphate-chloride solutions, stating results obtained by different workers. Writer also discusses various researches upon other solutions, with his own experiences and comments.

IRON AND STEEL

Canada. The Present Status and Future Possibilities of the Iron and Steel Industry in Canada, J. F. K. Brown. Iron & Steel of Can., vol. 4, no. 6, July 1921, pp. 159–166. Review of fundamental conditions of existence and growth of iron and steel manufacture, and discussion of advisability of capital investment in iron and steel enterprises in Canada.

England. Conditions in the Iron and Steel Industry. Engineer, vol. 131, no. 3417, June 24, 1921, pp. 675–676. Memorandum drawn up by British National Federation of Iron and Steel Manufacturers, representing employers, and Iron and Steel Trades Confederation, representing workmen.

Production on Pacific Coast. Factors in the Production of Iron and Steel on the Pacific Coast, Clyde E. Williams. Min. & Sci. Press, vol. 123, no. 3, July 16, 1921, pp. 94–96, 1 fig. Problem as to whether cheaper iron and steel can be obtained by producing them on Pacific Coast is said to depend upon a number of factors, chief among which are supply of raw material, amount and nature of market, and size and type of smelting operation. Paper presented at Int. Min. Convention, Oregon.

Protective Coatings. The Relative Values of Protective Metallic Coatings for Iron and Steel, Sherrard O. Cowper-Coles. Engineering, vol. 112, no. 2899, July 22, 1921, p. 167. Relative advantages and disadvantages of zinc coatings. Discusses four methods in which it can be applied, namely dipping in molten zinc, sherardizing, electro-zincing and spraying. Paper read before Instn. Civ. Engrs.

IRON CASTINGS

Loam Process. British Shop Casts Big Ingot Mold. Foundry, vol. 49, no. 14, July 15, 1921, pp. 565–566,

casting in Sheffield district. Casting annealed for two weeks. Special arrangements made for shipment 60 miles by rail.

Reversed Chilled. Reversed Chilling of Castings (Der umgekehrte Hartguss), P. Bardenheuer. Stahl u. Eisen, vol. 41, nos. 17 and 21, Apr. 28 and May 26, 1921, pp. 569–575 and 719–723, 32 figs. As results of investigation, the nature and origin of this phenomenon is explained. Outer zone of white congealed iron due to overcooling becomes gray through subsequent formation of graphite. Overcooling is due to a high sulphur content and a low casting temperature. Photomicrographs.

IRON FOUNDING

Centrifugal Casting. Chill Casting and Centrifugal Casting (La Coulée en Coquille et par Centrifugation) La Fonderie Moderne, no. 4, April 1921, pp. 87–89. Discusses operation of both methods.

IRON, PIG

Dephosphorizing. The Dephosphorizing of the Ilsed Basic Pig Iron in Converter and Open-Hearth Furnace (Die Entphosphorung des Ilseder Thomasroheisens im Konverter und im Martinofen), Arthur Jung. Stahl u. Eisen, vol. 41, no. 20, May 19, 1921, pp. 687–692. Describes dephosphorizing in open-hearth furnace of pig iron with 3 per cent phosphorus content and utilization of the phosphoric acid, with use of a poor and a rich ore in preliminary melting. Results are compared with basic process, which is said to insure a better utilization of phosphorus in pig iron.

Synthetic. Synthetic Production of Foundry Pig Iron and Its Properties (Synthetische Herstellung von Giessereiroheisen und dessen Eigenschaften), J. Bronn. Stahl u. Eisen, vol. 41, no. 26, June 30, 1921, pp. 881–888, 13 figs. Physical and chemical results of comparative tests of Rombach special process iron and Swedish charcoal pig iron show former to be of equal value, and its more frequent use is recommended.

J

JIGS

Design and Use. Jigs for Intensive Production. Eng. Production, vol. 3, no. 40, July 7, 1921, pp. 8–12, 14 figs. Observations on design and use of typical examples.

K

KEROSENE

Carburation of. Present State of Carburation of Kerosene (État Actual de la Carburation au Pétrole Lampant), Drosne. Société des Ingénieurs Civils de France, vol. 74, nos. 1, 2, 3, January-March 1921, pp. 35–52, 3 figs. Describes the Le Grain type of carburetor, fulfilling practically all required conditions.

L

LATHE TOOLS

Precision-Lathes. Tools Used in Making of Precision Lathe, Robert Mawson. Can. Machy., vol. 26, no. 1, July 7, 1921, pp. 68–69 and 74, 9 figs. Notes on different operations.

Ring Tools. The Ring Tool. Engineering, vol. 112, no. 2898, July 15, 1921, pp. 95–96, 5 figs. Article is said to complete geometry of ring tool and will be found useful for reference in drawing offices using these tools extensively.

LATHES

Manufacture. Making Flather Lathe Parts Interchangeable. Am. Mach., vol. 55, no. 2, July 14, 1921, pp. 50–53, 21 figs. Each part a separate unit. Jigs and fixtures eliminate individual fitting. All parts made to gages.

Turret. Obtaining Production on the Vertical Turret Lathe. Machy. (Lond.), vol. 18, no. 459, July 14, 1921, pp. 447–453, 18 figs. Application of vertical boring and turning mill to machine shop practice, including typical examples and description of tooling used.

Tooling in the Modern Turret Lathe. Eng. Production, vol. 3, nos. 42 and 43, July 21 and 28, 1921, pp. 61–66, 18 figs. and 83–89, 19 figs. Methods and fixtures for economical production.

LIGHTING

Charts and Data. Charts and Data for Industrial Lighting Designs, P. A. Powers. Elec. Rev., vol. 79, no. 7, August 13, 1921, pp. 231–234, 4 figs. Height of suspension related to spacing, reflector and lamp.

Illuminating Engineering. Illuminating Engineering, J. H. Asdell. Beama, vol. 9, no. 1, July 1921, pp. 25–29. Future field

Office Buildings. High-Intensity Illumination of Office Buildings, Ivan M. Kirlin. Elec. Rev. (Chicago), vol. 79, no. 7, August 13, 1921, pp. 235–238, 7 figs. Equipment employed and results obtained in lighting new offices of the Detroit Edison Co.

Railway Buildings. Electric Lighting of Railway Buildings, J. H. Kurlander. Ry. Elec. Engr., vol. 12, no. 7, July 1921, pp. 273–277, 11 figs. Three fundamental considerations of successful lighting installation are said to be intensity, quality and distribution. Recommendations.

LOCK WASHERS

Standards for. Current Standardization Work. 1921, pp. 118. Gives proposed dimensions of lock washers.

LOCOMOTIVE BOILERS

Repairing Cracks in Tubeplates. Repairing Cracks in the Copper Tubeplates of Locomotive Boilers, A. Wrench. Engineering, vol. 112, no. 2902, Aug. 12, 1921, pp. 251–252, 11 figs. Discusses methods of repairing.

Steel vs. Brass Tubes. Steel or Brass Boiler Tubes For Locomotives (Le Tube de Chaudiere de Locomotive acier ou Laiton?), O. Hock. Revue Universelle des Mines, vol. 10, no. 2, Series 6, July 15, 1921, pp. 117–128. Discusses the influence of the war and price of metals, life of steel tubes, etc. (To be continued.)

LOCOMOTIVES

Air-Operated Auxiliaries. Maintenance of Air Operated Auxiliaries. Ry. Mech. Engr., vol. 95, no. 8, August 1921, pp. 484–487, 5 figs. Discusses saving effected by the application of Air Brake Association condemning limits.

Booster Tests. Locomotive Booster Tests on Timiskaming & Northern Ontario Railway. Can. Ry. & Mar. World, no. 280, July 1921, pp. 356–357, 4 figs. Results of tests conducted with Can. Nat. Rys. dynamometer car 84.

British. Great Central Railway Four-Cylinder Engines—III. Supp. 3. Engineer, vol. 131, no. 3417, June 24, 1921, pp. 660–661, 5 figs. Characteristics: Type, 4-6-0; driving effort, 29,500 pounds; diameter of driving wheels, 5 ft. 8 in.

Heavy Locomotive Work on the Great Northern Railway (England). Ry. Gaz., vol. 35, no. 1, July 1, 1921, pp. 11–14, 3 figs. Passenger trains with 18 to 20 coaches and weighing from 590 to 650 tons are daily hauled between Doncaster and London by one engine of No. 1000 class. Discusses performance of locomotives on recent typical run.

Consolidation. High Capacity Consolidation Type Locomotives. Ry. Rev., vol. 69, no. 7, August 13, 1921, pp. 197–205, 13 figs. Discusses design and equipment, fuel consumption, fuel and tonnage performance, etc. Tractive effort, 68,200 lb.

Cut-off Control. The Automatic Control of Locomotive Cut-off, E. S. Pearce. Ry. Mech. Engr., vol. 95, no. 8, August 1921, pp. 488–493, 13 figs. Utilizing back pressure as actuating force.

Engine Design. Modern Locomotive Engine Design and Construction—LXXII. Ry. Engr., vol. 42, no. 498, July 1921, pp. 255–258, 2 figs. Considerations and factors determining most suitable cross section for locomotive connecting rods.

4-8-0. Recent Designs of Twelve-Wheel Locomotives. Ry. Age, vol. 71, no. 6, August 6, 1921, pp. 251–252, 4 figs. Description of various 4–8–0 types.

4-6-2 vs. 2-10-2. Heavy Locomotives for the Southern Pacific. Ry. Mech. Engr., vol. 95, no. 8, August 1921, pp. 481–483, 5 figs. Comparison between the 4-6-2 and 2-10-2 types. Tractive efforts are 43,660 and 75,150 lb., respectively.

Malay States Railways. Locomotives for Federated Malay States Railways. Ry. Age, vol. 71, no. 3, July 16, 1921, pp. 119–120, 3 figs. Locomotives manufactured by Baldwin Locomotive Works are of most up-to-date type and have open bar steel frames. Weight and dimensions are tabulated.

Mechanical Efficiency. Locomotive Resistance and Mechanical Efficiency, Kiichi Asakura. Ry. Age, vol. 71, no. 5, July 30, 1921, pp. 211–216, 9 figs. Establishes a formula for calculating mechanical efficiency.

Mikado. Heavier Mikado Type Locomotives Cut Operating Cost. Ry. Rev., vol. 69, no. 3, July 16, 1921, pp. 83–85, 3 figs. Improved type used on Baltimore & Ohio railroad handle 5800 tons over 0.3 per cent grade and are said to be more economical on account of ability to use mine-run coal.

Oil-Burning. Oil-Burning Locomotives in India and Mesopotamia, A. M. Bell. Ry. Engr., vol. 42, no. 498, July 1921, pp. 247–250, 6 figs. Information with regard to utilization of oil fuel for locomotives in the East.

Oil-Burning Locomotives on the Great Eastern Railway (England). Ry. Gaz., vol. 35, no. 1, July 1, 1921, pp. 9–10, 3 figs. Describes how G.E.R. locomotives are being fitted up for oil-fuel burning on the Holden system.

Shops, England. Methods Employed in the Locomotive Shops of the Great Western Railway Co., Swindon—IV. Machy. (Lond.), vol. 18, no. 458, July 7, 1921, pp. 405–407. Details of heat-treating plant and machining operations on various components of brake gear and link motion.

Southern Pacific Lines. New Pacific, Santa Fe and Switching Locomotives for the Southern Pacific Lines. Ry. & Locomotive Eng., vol. 34, no. 7, July 1921, pp. 199–200, 3 figs. Marked increase in weight and tractive power.

Superheaters. The Application of Superheaters to Light Locomotives. Ry. & Locomotive Eng., vol. 34, no. 7, July 1921, pp. 188–189, 5 figs. Examples of recent construction in which installations have been made.

Tank. Heavy Tank Locomotives on the London & South Western Railway. Ry. Gaz., vol. 35, no. 1, July 1, 1921, pp. 16 and 22, 2 figs. New 4-8-0 side tank locomotive built for work at Feltham concentration yard and for transfer service between Nine Elms and Feltham.

Tire-Fixing Appliance. A New Machine for Railway Work. Eng. Production, vol. 2, no. 39, June 30, 1921, p. 772, 1 fig. Appliance for use in connection with tire fixing.

Roller Bearings on. Roller Bearings on Looms. Textile World, vol. 60, no. 6, August 6, 1921, pp. 89–91, 2 figs. Shows a power saving of 23 per cent.

LUBRICATING OILS

Carbonization in Internal-Combustion Engines. The Carbonization of Lubricating Oils in Internal-Combustion Engines, Frederic H. Garner. Jl. Instn. Petroleum Technologists, vol. 7, no. 26, Apr. 1921, pp. 98–126 and (discussion and bibliography) pp. 126–148, 8 figs. Method of determining asphaltic resins in lubricating oils was devised by utilizing the selective absorbent power of animal charcoal. Results of experimental work on evaporation and carbonization of series of lubricating oils derived from Texas and Pennsylvania crudes.

Castor Oil. Castor Beans and Castor Oil, M. Riodl. So. African Jl. Ind., vol. 4, no. 6, July 1921, pp. 540–547. Discusses cultivation of the bean and use of castor oil as a lubricant.

Reclaimed. The Reclamation of Used Motor Oils, William F. Parish. Sci. Lubrication, vol. 1, no. 6, June 1921, pp. 5–7. Discusses the value of reclaimed oil and advocates its salvage.

Viscosity-Temperature Chart. A New Chart for Viscosity Temperature Relations. Lubrication, vol. 7, no. 6, June 1921, pp. 5–8, 2 figs. Presents chart, one of important features of which is that every known lubrication oil can be shown comparatively.

LUBRICATION

Steam-Cylinder. Steam cylinder Lubrication. Lubrication, vol. 7, no. 6, June 1921, pp. 1–4 and 9–13. Notes on what the oil must lubricate; how it can best be applied; conditions under which it must operate; selection of oils; and how to tell if lubrication is correct.

M

MACHINE GUNS

Dispersion. Long Range Small Arms Firing—IV, Glenn P. Wilhelm. Army Ordnance, vol. 2, no. 1, July-August 1921, pp. 31–35, 4 figs. Discusses dispersion, especially kinds of machine-gun dispersion.

Synchronizing with Airplane Propeller. Engineering Field of Aeronautics—XI, T. L. Sherman. Commonwealth Engr., vol. 8, no. 11, June 1, 1921, pp. 322–325, 3 figs. Discusses wave transmission as applied to secure synchronism of a machine gun with the propeller of an aeroplane engine.

MACHINE SHOPS

High- and Low-Bay Type. The High- and Low-Bay Type of Machine Shop, Fred H. Colvin. Am. Mach. vol. 55, no. 3, July 21, 1921, pp. 91–93, 7 figs. Wide, high bays, with low bays between, give light from both sides. Standard columns and shapes make rearrangement easy at any time.

MACHINERY

Foundation Bolts. Elements of Design for Foundation Bolts of Machines, Terrell Croft. Coal Age, vol. 20, nos. 2 and 3, July 14 and 21, 1921, pp. 45–51, 9 figs., and 95–99, 13 figs. Summary of available information concerning design of machinery foundations and holding-down bolts necessary. Devices to increase holding power of anchor bolts; relative value of neat cement, sulphur and lead.

MALLEABLE IRON

Structure. Explain the Structures of Malleable, W. R. Bean, W. H. Highriter and E. S. Davenport. Foundry, vol. 49, no. 14, July 15, 1921, pp. 557–564, 40 figs. Microscope reveals causes of many different effects found in fracture of malleable cast iron. Condition of carbon is said to be largely governed by composition and by anneal. Paper presented before Am. Foundrymen's Assn.

Sulphur in. Sulphur in Malleable Cast Iron, Lester C. Crome. Chem. & Met. Eng., vol. 25, no. 6, August 10, 1921, pp. 247–248. Discusses determination of sulphur in white cast iron by the evolution process.

MARINE STEAM TURBINES

Gearing. Marine Steam-Turbine Gearing, J. Hamilton Gibson. Trans. Inst. Mar. Engrs., session 1921–22, June 1921, pp. 115–126 and 127–143, 1 fig. on p. 144. Deals with essential elements of manufacture, erection and running.

MATERIALS

Storage. Principles of Storage. Iron Age, vol. 108, no. 4, July 28, 1921, pp. 194–196, 8 figs. Experience and practices of Pittsburgh railways summarized.

METAL SPRAYING

Schoop Process. Progress in Metal Coating, Schoop Process of Spraying Metals or Alloys (Les Progrès de la Métallisation, Procédé Schoop Par Pulverisation de Metaux ou Alliages Fondus), P. Nicolardot. Chimie & Industrie, vol. 5, no. 6, June 1921, pp. 619–635, 26 figs. Describes the Schoop process, apparatus and applications in industry.

METALLOGRAPHY

Foundry Uses. Use of Metallography in Metal Foundries (Anwendungen der Metallographie in der Metallgiesserei), Rudolf Stotz. Giesserei-Zeitung, vol. 18, nos. 13 and 14, July 5 and 12, 1921, pp. 207–211 and 215–220, 32 figs. Discusses internal structure of metals and alloys in relation to foundry practice. Address delivered before Assn. German Metal Foundrymen.

METALS

Annular Cracks. Annular Cracks, R. R. Clarke. Metal Industry (Lond.), vol. 19, no. 2, July 8, 1921, pp. 27–28, 2 figs. Discusses various theories for their formation.

Calorizing. Calorizing as a Protection for Metals, A. V. Farr. Forging & Heat-Treating, vol. 7, no. 7, July 1921, pp. 384–386, 4 figs. Also in Blast Furnace and Steel Plant, vol. 9, no. 7, July 1921, pp. 431–433. Recent developments. Characteristics of a good protective coat. Materials that can be calorized. Cost and various applications. (Abstract.) Paper read before Eng. Soc. West. Pa.

Protecting Metals by Calorizing (Les Méthodes de Protection des Métaux et la Calorisation), Léon Guillet. Revue de Métallurgie, vol. 18, no. 5, May 1921, pp. 283–289, 6 figs. Describes the three methods depending on (1) reaction of the metal itself, (2) adding another metal, and (3) non-metallic coating.

Properties at High Temperatures. Study of the Physical Properties of Metals at High Temperature. (Studio delle Proprieta Fisiche dei Metalli Alle Elevate Temperature Precedenti il Loro Intervallo di Plasticita). Il Forno Elettrico, vol. 3, no. 5, May 15, 1921, pp. 71–73. Particulars of experiments carried out and conclusions.

Scratches, Effect of. The Effects of Scratches in Materials, Ernest George Coker. Engineering, vol. 112, no. 2897, July 8, 1921, pp. 81–82. Effect of different kinds of scratches on stressed materials. Paper read before Instn. Civ. Engrs.

Viscosity. On the Determination of the Coefficient of Normal Viscosity of Metals, Kôtarô Honda and Seibei Konno. Lond., Edinburgh, & Dublin Philosophical Mag., vol. 42, no. 247, July 1921, pp. 115–123, 3 figs. Coefficients of twelve different metals are measured at room temperature, values ranging from 0.7×10^8 to 27×10^8. Annealing causes diminution of coefficient of viscosity; in carbon steels coefficient increases with content of carbon.

MICROMETERS

Screw. The Spreading of Micrometer Frames (Die Aufbiegung von Schraubenmikrometern), G. Berndt. Betrieb, vol. 3, no. 19, June 25, 1921, pp. 574–581, 12 figs. Results of experiments with a number of screw micrometers by different firms. A formula for calculation of semi-circular frames is developed. A table of permissible amounts of spreading of frames is presented and weights for rectangular cross-section frames are calculated.

MILLING MACHINES

Continuous. New 18-Inch Continuous Mill. Blast Furnace and Steel Plant, vol. 9, no. 7, July 1921, pp. 430–431, 4 figs. Recently completed by Whitaker-Glessner Co. at Portsmouth, Ohio. Consists of six stands of 18-in. roughing and finishing rolls together with two edging mills, located respectively in front of first and third roughing passes.

Whitaker-Glessner Continuous Mill. Iron Age, vol. 107, no. 26, June 30, 1921, pp. 1747–1749, 4 figs. For making sheet bars or billets. Includes edging rolls. Approach table with skewed V-groove rollers for centering blooms.

Universal. A New Universal Milling Machine. Eng. Production, vol. 3, no. 40, July 7, 1921, pp. 18–19, 2 figs. Details of latest motor-driven universal milling machine manufactured by J. Perkinson & Son, Shipley, England.

MOLDING MACHINES

Centrifugal. Centrifugal Molding Machine of E. O. Beardsley and W. F. Piper (Die Schleuderformmaschine von E. O. Beardsley and W. F. Piper. Stahl u. Eisen, vol. 41, no. 21, May 26, 1921, pp. 723–724, 1 fig. Refers to centrifugal molding machines described in same journal (Sept. 30, 1920) which are now being manufactured by the inventors in several forms, the most popular being the portable machine. Recent improvement.

French Practice. Mechanical Molding Practice (La Pratique de Moulage Mécanique), G. Pouplin. La Fonderie Moderne, no. 5, May 1921, pp. 128–137, 6 figs. Discusses various methods for molding grate bar and aluminum casings for motor cars.

Operation. Machine Molding (La Pratique de Moulage Mécanique). G. Pouplin. La Fonderie Moderne, no. 4, April 1921, pp. 92–102, 7 figs. Describes the operations in detail. (To be continued.)

MOLDING METHODS

Follow-Board Use. Accentuates Use of Follow Board Pat. Dwyer. Foundry, vol. 49, no. 15, August 1, 1921, pp. 585–590, 11 figs. Match plates extensively used in new foundry equipment.

Gating. Elevated, Midway, and Subway Gating, William H. Parry. Am. Mach., vol. 55, no. 6, Aug. 11, 1921, pp. 209–210, 8 figs. Using three-part flasks on two-part work to increase production. Arrangement of gates and runners. Abandoning horn gate.

Pipe Fittings. Large Elbow Made in Dry Sand Mold, James J. Zimmerman. Foundry, vol. 49, no. 15, August 1, 1921, pp. 607–610, 8 figs. Methods employed in the production of pipe fittings for 96-in. diameter exhaust line.

Sash Weights. How to Make Sash Weight Castings, J. H. Anderson. Foundry, vol. 49, no. 15, August 1, 1921, pp. 592–594, 5 figs. Shows how these castings can be produced rapidly and economically.

MOLYBDENUM STEEL

Motor Cars. Molybdenum Steel in the Motor Car. Sci. Am., vol. 125, no. 4, July 23, 1921, pp. 62–63, 4 figs. Notes on reducing weight in high-power cars by use of new steel alloys.

Physical Properties. The Value of Molybdenum Alloy Steels, G. W. Sargent. Trans. Am. Soc. Steel Treating, vol. 1, no. 10, July 1921, pp. 589–596 and (discussion) pp. 596–597, 5 figs. Notes on manufacture and physical properties.

MONEL METAL

Magnetic Properties. Monel Metal Has Definite Magnetic Properties, Charles W. Burrows. Elec. World, vol. 78, no. 3, July 16, 1921, pp. 115–116, 3 figs. Investigation shows magnetic characteristics considerably less than iron. Important property in loss of magnetism at temperature near 200 deg. fahr.

MOTOR-TRUCK TRANSPORTATION

Chicago. Motor Truck Haulage in Chicago. Elec. Ry. Jl., vol. 58, no. 4, July 23, 1921, pp. 133–135, 4 figs. North Shore line has receiving station close to Chicago Loop and hauls merchandise on trucks to rail terminal. Study shows service to be costly taken by itself, but valuable as business producer.

Development and Future. The Development and Future of Handling Freight by Motor Trucks. Jl. Engrs.' Club of Phila., vol. 38–6, no. 198, June 1921, pp. 225–240. Better Highways and Motor Transportation as an Aid to Production, F. W. Fenn. The Motor Truck and Legislation, R. A. Hauer. Motor Truck Operation in Southern Maryland, M. O. Eldridge. Discussions.

MOTOR TRUCKS

Cushioning in. Cushioning in Motor-Truck Design, Charles O. Guernsey. Jl. Soc. Automotive Engrs., vol. 9, no. 2, August 1921, pp. 143–147 and discussion pp. 147–150, 10 figs. Considers chassis stresses, cushion tires and wheels and elimination of vibration.

MUSKETS

Sights. Telescopic Musket Sights, H. K. Rutherford. Army Ordnance, vol. 2, no. 1, July-August 1921, pp. 23–30, 17 figs. Discusses ten different kinds of sights.

N

NICKEL STEEL

Deoxidizing. Method of Deoxidizing High-Nickel Steel, C. B. Callomon. Foundry, vol. 49, no. 15, August 1, 1921, pp. 590–591. Advocates use of pure manganese instead of aluminum.

O

OFFICE MANAGEMENT

Data Filing. Packard's Motor Transport Data Files, Dorsey W. Hyde, Jr. Filing & Office Management, vol. 6, no. 3, August 1921, pp. 71–73. Gives details of classification.

Government Departments. Office Management as Applied to Government Establishments, W. E. Mickey. Filing & Office Management, vol. 6. no. 3, August 1921, pp. 65–67, 2 figs. Outline of the work of the various departments.

OIL ENGINES

Crossley Solid-Injection. The Production of Power from Internal-combustion Engines, F. W. Burstall. Elecn., vol. 86, no. 2249, June 24, 1921, pp. 781–783, 2 figs. Details of the Crossley solid-injection heavy-oil engine of high-compression type, in which the charge is ignited by mixture itself at end of compression.

French. A New French Heavy Oil Engine, M. R. E. Mathot. Gas & Oil Power, vol. 16, no. 190, July 7, 1921, pp. 149–150, 1 fig. Describes new type built by Weyher & Richemond, Pantin, near Paris.

Marine. Some Observations on Marine Oil Engines, D. M. Shannon. Trans. Inst. Mar. Engrs., session 1921–22, June 1921, pp. 145–164 and (discussion) pp. 165–174, 15 figs. Deals with various types, including Diesel and hot-bulb engines. Diagrams from various types of piston engines.

OIL FUEL

Eyre System. Eyre System of Liquid Fuel Burning. Tramway & Ry. Wld., vol. 50, no. 3, July 14, 1921, pp. 9–11, 8 figs. This system is extremely simple and suitable for all kinds of furnace work and steam-raising purposes.

Mexican. The Production and Combustion of Mexican Fuel Oil—IV. J. M. Pettingell and J. R. Carlson. Combustion, vol. 5, no. 2, Aug. 1921, pp. 66–69, 5 figs. Fuel oil and coal comparison.

Production. Fuel Oil, W. A. Whyte. Steamship, vol. 33, no. 385, July 1921, pp. 6–12. Notes on origin, finding and refining of petroleum; statistics of output. Fire precautions and appliances for use on ships burning oils. Paper read before North-East Board of Engrs. & Shipbuilders.

OIL WELLS

Cementing. The Cementing of Oil Wells. Petroleum Times, vol. 6, no. 130, July 2, 1921, pp. 13–14, 1 fig. Details of the Halliburton cementing process.

Drilling. Drilling Oil Wells With the Diamond Drill, Frank A. Edson. Bul. Am. Assn. Petroleum Geol., vol. 5, no. 3, May-June 1921, pp. 386–393. Maintains that the diamond drill affords a means of obtaining much more accurate information and at no greater cost.

Study on Drilling and Behavior of Neighboring Wells, A. W. Ambrose. Oil Field Eng., vol. 23, no. 7, July 1921, pp. 86–88. (From U. S. Bur. of Mines, Bul. 195). Advocates the exchange of information, speaks of the necessity for testing drilling well and testing samples of information for oil.

Mud Injection. Introducing Mud-Laden Fluid Under High Pressures Into Porous Formations, H. J. Steiny. Eng. & Min. Jl., vol. 112, no. 5, July 30, 1921, pp. 182, 1 fig.

OILS

Animal, Hydrogenation of. Hydrogenation of Some Marine Animal Oils (Hydrogénation de quelques huiles d'animaux marins), H. Marcelet. Académie des Sciences, vol. 173, no. 2, July 11, 1921, pp. 104–107. Shows favorable results from experiments carried out.

Linseed. Improved Process of Refining Linseed Oil, Alexander Schwarcman. Chem. Age (N. Y.), vol. 29, no. 7, July 1921, pp. 280–282. Writer describes process developed by him and mechanical equipment required therefor.

Vegetable. Solvent Extraction in the Vegetable Oil Industry, J. H. Shrader. Chem. & Metallurgical Eng., vol. 25, no. 3, July 20, 1921, pp. 94–100, 6 figs. Stationary and rotary types of extractors; principal solvents; economic considerations; uses of products obtained.

OPEN-HEARTH FURNACES

Egler Blow-Torch Port. The Egler Blow-Torch Port for Open-Hearth Furnaces. Iron & Coal Trades Rev., vol. 102, no. 2782, June 24, 1921, pp. 846–847, 2 figs. Details of Egler furnace said to be equally adapted to all kinds of gas or liquid fuel and to powdered coal.

Improvements. Improvement in Open-Hearth Details, A. G. and A. F. Schumann. Iron Age, vol. 108, no. 5, Aug. 4, 1921, pp. 269–272, 8 figs. New arrangement of reversing furnace valves promotes economy. Burners for liquid fuel and tar. Results in operation.

Relation of Temperature to Output. Discussion on Open Hearth Practice, Henry Wm. Seldon. Blast Furnace and Steel Plant, vol. 9, no. 7, July 1921, pp. 422–423. Facts to be considered in relation to open-hearth furnace temperature to furnace output.

OXY-ACETYLENE WELDING

Refrigerating Apparatus. Oxy-Acetylene Welding of Refrigerating Apparatus, Fred E. Rogers. A.S.R.E. Jl., vol. 7, no. 6, May 1921, pp. 432–450 and (discussion) pp. 450–451, 27 figs. Discusses the importance of true forms, manipulation of torch and welding rod, reinforcement of welds, size of welding rods and tips, etc.

P

PARACHUTES

Types. Saving Life in Air Wrecks, T. Orde Lees. Aeronautical Jl., vol. 25, no. 127, July 1921, pp. 317–328 and (discussion) pp. 328–332. Discusses saving of passengers and crew by parachute. Different types of parachutes are described.

PEAT

Pulverized. Pulverized Peat Fuel a Success, C. L. Bohannan. Jl. Am. Peat Soc., vol. 14, no. 3, July 1921, pp. 19–25. It is claimed that use of pulverized fuel produces a great saving in both fuel and labor costs.

Russian Plants. Russian Machine-Cut Peat Plants (Russische Maschinentorfanlagen), A. Naumann. Fördertechnik u. Frachtverkehr, vol. 14, no. 4, Feb. 18, 1921, pp. 50–51. It is claimed that the Russian machine-cut peat plants are the most perfect of their kind in existence.

PIPE, CAST-IRON

Explosion. Explosion of a Cast-Iron Steel Pipe Engineering, vol. 112, no. 2898, July 15, 1921, p. 102. Results of investigation shows that explosion was due to improper overhauling of drain trap.

PIPE FITTINGS

Casting. Casting Large Pipe Fittings, James J. Zimmerman. Blast Furnace and Steel Plant, vol. 9, no. 7, July 1921, pp. 417–420, 9 figs. Scott Foundry, Reading, Pa., makes 96-in. elbows for 10,000-kw. installation for steel plant, in dry sand mold. Describes methods.

PIPE, WOOD-STAVE

Use of. Construction of Wood Pipe Lines (Der Bau hölzerner Rohrleitungen), Leopold Nosseck. Zeit. des Oesterr. Ingenieur- u. Architekten-Vereines, vol. 73, nos. 1–2 and 24–25, Jan. 14 and June 24, 1921, pp. 13–14 and 166–168, 5 figs. Summary of conditions favorable to use of and advantages of wood-stave pipe.

PISTONS

Machining. Machining Motor Pistons. Machy. (Lond.), vol. 18, no. 458, July 7, 1921, pp. 428–429, 3 figs. Successive steps and equipment employed in machining pistons for high-grade motor car.

PLANERS

Crank-Driven. Results Obtained with Crank-driven Planers. Machy. (Lond.), vol. 18, no. 458, July 7, 1921, pp. 415–419, 9 figs. Methods of operating machines possessing features of both planer and shaper.

PLATES

Reinforced-Concrete. Load Distribution in Reinforced-Concrete Plates Supported on Both Sides and under Concentrated Load Lastverteilung bei zweiseitig aufliegenden Eisenbetonplatten mit konzentrierter Belastung), W. Petry. Beton u. Eisen, vol. 20, no. 4–5, Mar. 7, 1921, pp. 60–62. Results of tests carried out by German Committee for Reinforced Concrete in the material-testing station of the Stuttgart Technical Academy.

Dundee, Scotland. Power Supply in Dundee. Elecn., vol. 87, no. 2252, July 15, 1921, pp. 70-76, 8 figs. Account of progress. Notes on supply conditions, coal and ash handling, boiler house, flues and economizers, feed pumps, generating plant, generators, switchgear, sub-stations, transmissions and distribution.

Generating Costs. Generating Costs in Stations of Medium Size, M. J. Idail. Elec. World, vol. 78, no. 4, July 23, 1921, pp. 169-170. Southern station burning Mexican fuel oil averages $1.37 cents per kw-hr.; another station with river washery coal averages $1.24.

Glasgow, Scotland. Dalmarnock Power Station, R. B. Mitchell. Elec. Ry. & Tramway Jl., vol. 44, no. 10, June 10, 1921, pp. 261-271, 26 figs. Describes Glasgow plant completed in 1920. Summary of important data concerning boilers, turbo-alternators condensing plant, motors driving auxiliaries, alternators, step-up transformers, switchgear, and other equipment.

POWER TRANSMISSION

Types of Drive. Progress and Problems of the Mechanical Transformation of Energy (Fortschritte und Probleme der mechanischen Energieumformung) K. Kutzbach. Zeit. des Vereines deutscher Ingenieure, vol. 65, no. 26, June 25, 1921, pp. 673-678, 21 figs. Deals with high-speed toothed-gear drive for ship turbines, stationary turbines, electric locomotives and hydroelectric plants; and gives examples of belt and rope drives, typical for trend of recent development.

PRESSES

Design. Designing Power Press Frames. Eng. Prod., vol. 3, no. 43, July 28, 1921, pp. 76-78, 2 figs. Data for use in determining the leading dimensions.

PULVERIZED COAL

Foundries. Powdered Coal Applied in Foundry, A. J. Grindle. Foundry, vol. 49, no. 15, August 1, 1921, pp. 617-618. Layout and operation of a powdered-coal installation.

German Steel Industry. Powdered Coal as Fuel for Boilers, F. Schulte. Blast Furnace and Steel Plant, vol. 9, no. 7, July 1921, pp. 447-452, 4 figs. Application in German steel industry. Translated from Glückauf, Apr. 30, 1921.

Properties. Powdered Fuel, Robert James. Proc. South Wales Inst. Engrs., vol. 37, no. 3, July 7, 1921, pp. 221-236. Continuation of the discussion of Robert James' paper.

Steam Generation. Pulverized Firing in Steam Generation, F. J. Crolius. Blast Furnace and Steel Plant, vol. 9, no. 7, July 1921, pp. 453-460. Discusses use of pulverized coal. Typical layout of successfully operated plant.

Steel Works. The Adaptability of Pulverized Coal Furnaces for Iron and Steel Works (Anwendbarkeit der Kohlenstaubfeuerung in Eisenhüttenwerken), G. Bulle. Stahl u. Eisen, vol. 41, no. 29, July 21, 1921, pp. 985-994, 6 figs. Advantages of firing with pulverized coal from technical and economic standpoint.

Trent Cleaning Process. Trent Process for Cleaning Powdered Coal, O. P. Hood. Iron Age, vol. 108, no. 6, Aug. 11, 1921, p. 323. Agitation method of producing an amalgam and eliminating ash from low-grade fuels.

PUMPING STATIONS

Cleveland. The Division Pumping Station at Cleveland, Ohio, J. N. H. Christman. Jl. Am. Water Wks. Assn., vol. 8, no. 4, July 1921, pp. 433-441. Particulars of construction and equipment.

PUMPS

Boiler-Feed. Water and Air Pumps for Small Deliveries with Eccentric Drive (Wasser-und Luftpumpe für geringe Fördermengen mit Antrieb durch Exzenter), H. Mitusch. Fördertechnik u. Frachtverkehr, vol. 14, no. 3, Feb 4, 1921, pp. 33-34, 5 figs. Description and illustrations demonstrating arrangement of pumps with eccentric drive for use where crank drive is inexpedient.

PUMPS, CENTRIFUGAL

Piston vs. Centrifugal Versus Piston Pumps (Kreiselpumpe oder Kolbenpumpe?) Alfred Schacht. Fördertechnik u. Frachtverkehr, vol. 14, no. 7, Apr. 1, 1921, pp. 79-80, 1 fig. Cost of installation of centrifugal pump is said to be about half that of steam piston pump, and foundations can be easily and cheaply constructed. Condensation water of turbine is free of oil and can be directly reused for boiler feed.

Reciprocating Pumping Engines vs. Comparison between Reciprocating Pumping Engines and Turbo-driven Centrifugal Pumps, Hugh Lupton. Engineering, vol. 112, no. 2897, July 8, 1921, pp. 74-76. Includes tables showing consumptions and costs of triple-expansion pumping engines and steam turbine-driven centrifugal pumps. Paper read before Instn. Civ. Engrs.

PUNCHES

Design. The Design and Construction of Press Tools—X. Eng. Production, vol. 3, no. 42, July 21, 1921, pp. 56-58, 6 figs. Considers various kinds of punches and dies. (Concluded.)

PYROMETERS

Equipment for. Some Essentials of Modern Pyrometer Equipment, H. G. Hall. Can. Machy., vol. 26, no. 3, July 21, 1921, pp. 38-40, 4 figs. Discusses simplicity of design, cost of thermocouple upkeep, etc.

R

RADIOMETALLOGRAPHY

Spectral Analysis of Metals. Radiometallography (La Radiométallographie), E. Dieudonné. Revue Universelle des Mines, vol. 9, no. 6, June 15, 1921, pp. 557-566, 8 figs. Concludes that by it the spectral analysis of metals has been made possible.

RAILS

Damage Due to Deceleration. Damage to Tyres and Rails Caused by Brakes or Slipping Wheels, Christer P. Sandberg. Engineering, vol. 112, no. 2897, July 8, 1921, pp. 82-84, 8 figs. Two examples of rail failure are given which are said to be typical of many others for which no adequate explanation has been found. Paper read before Instn. Civ. Engrs.

Failures. Split-Head Rail Failure Shows Rupture, James E. Howard. Iron Age, vol. 108, no. 7, Aug. 18, 1921, pp. 393-395, 7 figs. Differs from a piped rail and is often more easily discovered by outcropping at side. (Abstract.) Report of Interstate Commerce Commission.

Fissures. A New Theory of Fissure Formation (Eine neue Theorie der Riffelbildung), A. Wichert. Verkehrstechnik, vol. 38, nos. 9 and 11, Mar. 25 and Apr. 15, 1921, pp. 109-113 and 140-143, 7 figs. New theory of fissuring is developed and means of preventing it described. Details of apparatus for investigation of formation of fissure designed by author and built by Greater Berlin Street Railway, tests with which are to be carried out by Brown, Boveri & Cie., Mannheim.

Specifications. A New Rail Specification Proposed, Robert W. Hunt. Iron Age, vol. 108, no. 5, Aug. 4, 1921, pp. 262-263. Provides for rolling tie plates from top of each ingot. Treatment in soaking pits. Lenient as to cold straightening.

New Specification for Rails, Robert W. Hunt. Ry. Age, vol. 71, no. 6, August 6, 1921, pp. 255-256. New specifications to compose difference between existing rail-makers and users.

Welding. Welding of Rails by Aluminothermic Processes, (La soudure des rails de tramways par les procédés aluminothermiques), M. Guiffart. L'Industrie des Tramways, vol. 15, no. 171-172, March-April 1921, pp. 41-47, 9 figs. Practice of French General Company of Tramways.

RAILWAY ELECTRIFICATION

Brazil. Electrification of the Paulista Railway of Brazil, W. D. Bearce. Ry. Age, vol. 71, no. 2, July 9, 1921, pp. 80-83, 5 figs. Fuel scarcity forces the adoption of electric motive power on Brazilian wide-gage line.

Switzerland. The St. Gothard Electrification. Elec. Ry. & Tramway Jl., vol. 45, no. 1086, July 8, 1921, pp. 17-20, 6 figs. Has adopted single-phase system, 15 periods, at 7,500-15,000 volts on the contact line. Reasons for this choice are discussed.

RAILWAY OPERATION

Demountable Car Bodies. Speeding Up Terminal Operations. Ry. Gaz., vol. 35, no. 5, July 22, 1921, pp. 218, 8 figs. Describes the use of demountable bodies in conjunction with motor chassis to speed up the handling of traffic.

Heavy-Tonnage. Heavy Tonnage Train Handling Demonstrations on Virginian. R. R. Herald, vol 25, no. 8, July 1921, pp. 23-27, 4 figs. Account of series of heavy-tonnage train-handling demonstrations conducted on Virginian R. R. under auspices of Westinghouse Air Brake Co., which successfully illustrated feasibility of handling trains approximating 16,000 tons gross behind locomotive, even when undertaking involves long descending mountain grades.

Locomotive Fuel-Oil Stations. Design and Operation of Locomotive Fuel Oil Stations. Eng. News-Rec., vol. 87, no. 5, Aug. 4, 1921, pp. 183-187, 9 figs. Tank cars discharge into track troughs; storage and service tanks; gravity of pumped supply to engines; oil columns; fire protection.

Train Control. Problems of Automatic Train Control. Ry. Gaz., vol. 35, no. 3, July 15, 1921, pp. 124-125. Discusses questions in connection with the prevention of accidents.

The Train Control System of the Midland Railway. Ry. Gaz., vol. 35, no. 2, July 8, 1921, pp. 45-97, 72 figs. partly on supp. plates. Comprehensive review of successful scheme of traffic in which all train-operating arrangements are centralized. Outstanding feature of scheme is said to be its simplicity. Includes figures indicating running efficiency secured by means of control system.

RAILWAY SHOPS

Power and Light for. Electric Power and Light for Railroad Shops, J. E. Gardner. Ry. Mech. Engr., vol. 95, no. 8, August 1921, pp. 515-518, 1 fig. Trend of development and standards adopted in the power and lighting field.

RAILWAY SIGNALING.

Alternating-Current. Principles of Alternating Current Signaling, J. S. Holliday. Ry. Signal Engr., vol. 14, no. 7, July 1921, pp. 267-269, 3 figs. Vector combinations and solutions of resistances of impedances. (Continuation of serial.)

Maintenance of A. C. Signal Apparatus, L. F. Vieillard. Ry. Signal Engr., vol. 14, no. 8, August 1921, pp. 229-302, 3 figs. Discusses relays, impedance bonds, resistances and reactances, transformers, etc. (To be continued.)

Farm-Lighting Unit. Farm Lighting Units for Signal Operation, F. H. Bagley. Ry. Signal Engr. system for charging storage batteries at central locations in territory where alternating current is not available.

Floating Battery. A. C. Floating Battery for Railway Signaling. Ry. Signal Engr., vol. 14, no. 8, August 1921, pp. 303-306, 6 figs. Comparison of this new system with straight a.c. and d.c. signaling and points to be considered in estimates.

New Signals and Interlockers. New Signals and Interlockers on the P. & R., B. V. Strickland. Ry. Signal Engr., vol. 14, no. 7, July 1921, pp. 256-261, 10 figs. Details of extensive improvements and additions to signaling system on New York branch of Phila. & Reading road. Notes on pole line construction, power supply, signal lighting, automatic block signaling, etc.

Position-Light Signals. The Development of Position-Light Signals, A. H. Rudd. Ry. Signal Engr., vol. 14, no. 7, July 1921, pp. 264-266, 1 fig. Latest design of Pennsylvania Railroad is said to reduce cost of operation and maintenance and promote simplicity and safety.

RAILWAY SWITCHES

Low-Voltage Machines. Switch Operation by Low-Voltage Machines, C. C. Anthony. Ry. Signal Engr., vol. 14, no. 8, August 1921, pp. 313-315, 1 fig. Discusses where these machines are best employed and their advantages.

RAILWAY TIES

Hollow Steel. Hollow Steel Ties (Die eiserne Hohlschwelle und die Wirtschaftlichkeit der Bahnunterhaltung), A. Birk. Verkehrstechnik, vol. 38, no. 12, Apr. 25, 1921, pp. 154-156, 6 figs. Describes R. Scheibe's hollow steel ties and compares their elastic properties and weights with those of other ties. Results of tests.

RAILWAY TRACK

Ashpits. Locomotive Ash-Pit and Coaling Station at Communipaw, New Jersey. Engineering, vol. 112, no. 2898, July 15, 1921, pp. 125-127, 8 figs. The two double submerged pits consist of rectangular reinforced-concrete tanks with piling foundations. Coaling station consists of reinforced-concrete structure spanning eight tracks to any of which any of three kinds of coal can be delivered.

REFRACTORIES

Carborundum. Carborundum Refractories in Heat Treating Furnaces, M. L. Hartman. Trans. Am. Soc. Steel Treating, vol. 1, no. 10, July 1921, pp. 601-603. Points out success resulting from adoption of carborundum refractories in various heat-treating furnaces.

Hardness when Heated. Arrangement For Testing the Hardness of Refractory Materials At High Temperatures (Sur un dispositif pour les essais de dureté des matériaux refractaires a haute temperature), Etienne Rengade & Edmond Desvignes. Comptes rendus de l'Académie des Sciences, vol. 173, no. 3, July 18, 1921, pp. 134-137, 1 fig. Description of a new apparatus superseding the Seger cone.

Rotary Cement Kilns. Refractories for Rotary Cement Kilns, Raymond M. Howe. Cement, Mill & Quarry, vol. 19, no. 1, July 5, 1921, pp. 35-36. Service in clinker zone is said to tax refractory materials. Effect of high temperature and changes in temperature. Other materials. Paper read before Portland Cement Assn.

REFRIGERATING MACHINES

Ammonia. Investigations of an Ammonia Refrigerating Machine (Untersuchungen an einer Ammoniak-Kältemaschine), Walther Fischer. Zeit. des Vereines deutscher Ingenieure, vol. 65, no. 27, July 2, 1921, pp. 720-723, 7 figs. Deals especially with influence of cooling water jacket on compressor.

Compression. The Compression Refrigerating Machine, Gardner T. Voorhees. Ice & Refrigeration, vol. 61, no. 1, July 1921, p. 23. Gage pressure.

REFRIGERATING PLANTS

Propellers for Brine Agitation. Modern Propeller Design for Brine Agitation and Circulation, E. A Burrows. Ice & Refrigeration, vol. 61, no. 1, July 1921, pp. 18-19, 10 figs.

RESEARCH

University. The University and Research, Vernon Kellogg. Chem. Age (N. Y.), vol. 29, no. 7, July 1921, pp. 274-276. Notes on work of Nat. Research Council, and conditions of university research. Paper read at University of Minn.

RIVETED JOINTS

Design. Principles of Riveted Joint Design, William C. Strott. Boiler Maker, vol. 21, no. 7, July 1921, pp. 191-193 and 212, 6 figs. Discusses types of plate and rivet failures, joint efficiency and calculations involved in determining strength of given riveted seam. (To be continued.)

RIVETING

Gas Rivet Heating. Experience with Gas Rivet Heating in the Pacific Coast, Letson Balliet. Eng. News-Rec., vol. 87, no. 1, July 7, 1921, pp. 21-22. Shipyard results show better rivets and saving of time and cost. Possibilities for structural work.

ROLLING MILLS

Chilled Rolls. Chilled Rolls for Rolling Mills (Cylindres de Laminoirs en Fonte trempée), Christian Kluytmans. La Fonderie Moderne, no. 4, April 1921, pp. 81-83. Discusses composition, silicon and other content, and tempering.

Modern Practice. Principles of Modern Rolling Practice, E. Cotel. Iron Age, vol. 108, no. 7, Aug. 18, 1921, pp. 396–399, 6 figs. Discussion of great power required for finishing passes. Phenomenon of speed gain (bar acceleration) in rolling. Translated from Montanistische Rundschau.

Roll Design. The Logic of Roll Design, W. H. Melaney, Part IV. Blast Furnace & Steel Plant, vol. 9, no. 8, August 1921, pp. 477–478, 1 fig. Discusses maximum draft of each pass and minimum diameter of roll.

Roll Making. How Steel Mill Rolls Are Made—I, H. E. Diller. Foundry, vol. 49, no. 15, August 1, 1921, pp. 595–601, 10 figs. Description and illustration of process.

Scullin Steel Co. Steel Rolling Mills of the Scullin Steel Company at St. Louis, Mo. (Les Laminoirs de l'Aciérie de la Scullin Steel Company à Saint-Louis, Missouri, E.-U.). Le Génie Civil, vol. 79, no. 1, July 2, 1921, pp. 1–5, 7 figs. Detailed description of plant and equipment.

ROOF TRUSSES

Design. Basic Principles for the Design of Arched Roof Trusses without Tie Rods (Entwurfsgrundlagen für zweistielige Bogenhallenbinder ohne Zugband), Otto Fröhlich. Beton u. Eisen, vol. 20, no. 2–3, Feb. 4, 1921, pp. 34–38, 7 figs. Tables and calculations supplementing those for arched roof trusses with tie rod developed by author and published in same journal (nos. 9–10, 1919).

ROPE DRIVE

Grünig Pulley. The Grünig Single-Groove Rope Driving Pulleys (Die einrillige Seiltreibscheibe nach dem Patente des Ing. Albert Grünig), Gustav Ryba. Montanistische Rundschau, vol. 13, nos. 11, 12 and 13, June 1, 16 and July 1, 1921, pp. 203–206, 225–228 and 247–249, 10 figs. Points out disadvantages of multiple driving pulleys and describes principles and construction of Grünig's patented single-groove pulley.

S

SCIENTIFIC MANAGEMENT

See INDUSTRIAL MANAGEMENT.

SEAPLANES

Types. Hydroplanes (Les Appareils Marins d'Aviation), Guitton. L'Aéronautique, vol. 3, no. 25, June 1921, pp. 229–231, 1 fig. Describes the Bréguet Caudron, Savoia and Farman types.

SEMI-DIESEL ENGINES

Small Central Stations. Semi-Diesel Engines in Small Central Stations, W. S. Barnes. Power, vol. 54, no. 3, July 19, 1921, pp. 96–97, 2 figs. Describes 250-hp. engine direct-connected to an alternator. Typical log sheet covering 24-hr. period of operation shows remarkably high fuel economy at varying loads as well as over-all economy.

SHAFTS

Critical Speeds. On the Critical Velocity of Shafts (Sulle Velocita Critiche Degli Alberi), Pietro E. Brunelli. L'Industria, vol. 35, no. 12, June 30, 1921, pp. 269–272, 4 figs. Mathematical calculations for various given conditions.

Large, Straightening. Straightening a Large Shaft by the Heat Process, Frank G. Frost. Proc. La. Eng. Soc., vol. 7, no. 2, Apr. 1921, pp. 85–91, 2 figs. Details of straightening a shaft of a vertical Curtis turbo-generator in a New Orleans generating station.

SHEARS

Heavy. Heavy Shears Without Flywheel (Schwere Blechschere ohne Schwungrad). Zeit. des Vereines deutscher Ingenieure, vol. 65, no. 28, July 9, 1921, pp. 744–746, 6 figs. Details of shears built by Thyssen & Co. Corp. Machine Works, Mulheim, cutting plates up to 45 mm. thick and 3000 mm. wide out of steel with tensile strength of 700 kg. per sq. mm. Advantages over shears with flywheel.

SLAG

Blast-Furnace. Color Classification of Blast Furnace Slags, Wallace G. Imhoff. Blast Furnace and Steel Plant, vol. 9, no. 7, July 1921, pp. 433–434. Scientific investigation on nature of slag itself; color classification of slags of value to blast-furnace men. (To be continued.)

SPRINGS

Flat. Design of Flat Springs, Joseph Kaye Wood. Am. Mach., vol. 55, no. 2, July 14, 1921, pp. 46–49, 5 figs. Importance of "spring criterion." Derivation of formulas. Triangular-shaped flat springs. Work and resilience in cantilever springs.

Helical. A Chart for the Design of Helical Wire Springs, R. Brooks. Engineering, vol. 112, no. 2900, July 29, 1921, pp. 173–175, 9 figs. Expressions are developed on which diagrams are built up, and from these the complete proportions of a spring to meet any required specification can be determined with practically no calculation.

STANDARDIZATION

Holland. Standardization in Holland (Normung in Holland), Ernst Hijmans. Betrieb, vol. 3, no. 19, June 25, 1921, pp. 582–595, 12 figs. Discussion of fundamental principles underlying standardization in Holland. Examples of standard sheets.

German N.D.I. Reports. Report of the German Industry Committee on Standards (Mitteilungen des Normenausschusses der Deutschen Industrie). Betrieb, vol. 3, no. 19, June 25, 1921, pp. 283–292, 16 figs. Proposals of Board of Directors for studs with journal ends; screw-end pins; set screws with various kinds of points; hexagonal cap screws, etc. Proposed new standards for round-head, flat and oval-head countersunk head machine screws with rolled threads.

Report of the German Industry Committee on Standards (Mitteilungen des Normenausschusses der Deutschen Industrie). Betrieb, vol. 3, no. 17, May 25, 1921, pp. 247–255, 12 figs. Proposal of Board of Directors for drawings; shank and sleeve tapers; chamfering and grooving; 45-deg. Y-branches, offsets and double Y-branches; basement sink-water traps. Proposed standards for drawings for helical, spiral and laminated springs; hoisting chains, both calibrated and uncalibrated.

Report of the German Industry Committee on Standards (Mitteilungen des Normenausschusses der Deutschen Industrie). Betrieb, vol. 3, no. 18, June 10, 1921, pp. 259–266, 7 figs. Proposal of Board of Directors for universal joints and shafts therefor. Proposed new standards for indicator cocks; metal screw inserts for insulated handles; solid insulated handles and knobs.

STEAM-ELECTRIC PLANTS

Fuel Economy. Cutting Coal Consumption a Third. Elec. Ry. Jl., vol. 58, no. 7, August 13, 1921, pp. 232–237, 10 figs. Describes improvements made in the power plant of Wilmington and Philadelphia Traction Co.

STEAM POWER PLANTS

Candy Factory. Power for Candy Making. Power Plant Eng., vol. 25, no. 15, August 1, 1921, pp. 743–747, 6 figs. Robt. A. Johnston Co.'s plant in Milwaukee. Installations of power-generating, refrigerating and air-conditioning equipment.

Modern Type. New Plant of the Continental Motors Corporation. Power Plant Eng., vol. 25, no. 16, August 15, 1921, pp. 789–796, 13 figs. Discusses coal- and ash-handling equipment, the boiler room, turbine room, auxiliaries and instruments.

STEAM TRAPS

Sugar Factories. Meditations on Trapology—III, J. O. Frazier. Int. Sugar Jl., vol. 23, no. 271, July 1921, pp. 382–385, 1 fig. The role of the steam trap in the sugar factory. (To be continued.)

STEAM TURBINES

Critical Speeds. The Calculation of Critical Speeds. Engineering, vol. 112, no. 2896, July 1, 1921, pp. 1–2, 3 figs. Discusses Bauman's rule for critical speed of turbine rotors.

High-Capacity. Steam Turbines for Limit Performances (Die Dampfturbinen für Grenzleistungen), A. Loschge. Zeit. des Vereines deutscher Ingenieure, vol. 65, no. 28, July 9, 1921, pp. 739–744, 10 figs. Development of the limit-performance turbine; influence of low-pressure blading on limit output. Calculation of strength of blades; limits of maximum capacity. Different construction types. Significance of super-critical velocity of steam.

Modern Types. Recent Advances in Steam Turbine Design, Gerald Stoney. Elecn., vol. 86, no. 2249, June 24, 1921, pp. 774–780, 14 figs. Details of various modern types. Notes on high-vacuum difficulties; disadvantages of higher blade speeds; effects of high steam temperature; bending troubles; blading material; advantages of Monel metal; etc.

STEEL

Artificial Seasoning. Artificial Seasoning of Steels, H. J. French. Chem. & Metallurgical Eng., vol. 25, no. 4, July 27, 1921, pp. 155–158. Review of available data on length changes and spontaneous generation of heat in hardened steels, together with results of preliminary experiments on artificial seasoning by different methods of several types of steels used for making limit gages.

Cold-Drawn. Production and Uses of Cold-Drawn-Steel, C. E. Bregenzer. Iron Age, vol. 108, no. 3, July 21, 1921, pp. 135–136, 1 fig. Annual output estimated at 900,000 tons. Automobile field largest consumer.

Motor-Valve. Steels for Internal-Combustion Motor Valves—II, G. Gabriel. Automotive Mfr., vol. 43, no. 3, June 1921, pp. 16–17 and 26–27. Details of various steels tested and results obtained. Enumeration of desirable and undesirable properties. Kinds of steel recommended.

Low-Carbon, Forging Tests with. Forging Tests with Low-Carbon Steel (Schmiedeversuche an Flusseisen), Paul Junkers. Stahl u. Eisen, vol. 41, no. 20, May 19, 1921, pp. 677–687, 23 figs. Results of tests with two grades of low-carbon steel containing 0.13 and 0.50 per cent carbon respectively, carried out for purpose of determining influence of reduction of cross-section and of forging temperature on mechanical properties and structure; also resistance of iron to deformations at different temperatures.

Nitrogen in. An Occurrence of Nitrogen in Steel, A. A. Blue. Iron Age, vol. 108, no. 1, July 7, 1921, pp. 1–5, 20 figs. Effect of gases on a light forging left accidentally in a furnace flue. Critical analysis of resulting structures.

Overstrain. Effect of Overstrain on the Elastic Properties of Steel. Iron & Coal Trades Rev., vol. 103, no. 2785, July 15, 1921, pp. 73. (From R. D. Report No. 45, Research Dept. at Woolwich.) Gives a summary of tests carried out with overstrained steels.

Pickling, Effect of. Embrittling Effect of Pickling Upon Carbon Steel, C. J. Morrison. Iron Age, vol. 108, no. 6, Aug. 11, 1921, pp. 334–335, 3 figs. Study of grain sizes shows that pickling increases width of junction lines between grains.

Properties and Mibrostructure. Properties and Miscrostructure of Heat Treated Nonmagnetic, Flame, Acids add Rust Resisting Steel, Charles M. Johnson. Trans. Am. Soc. Steel Treating vol. 1, no. 10, July 1921, pp. 554–575, 47 figs. Describes certain unusual properties of steel produced as result of author's study of steels. Photomicrographs.

Properties at High Temperatures. Investigation of the Mechanical Properties of Steels at High Temperatures (Recherches expérimentales sur les propriétés mécaniques des aciers aux températures elevées), Eugene Dupuy. Révue de Métallurgie, vol. 18, no. 6, June 1921, pp. 331–365, 39 figs. Detailed study of fracture and elongation, giving experimental results.

Specifications. Proposed Revised Specifications for Steel Products. Blast Furnace & Steel Plant, vol. 9, no. 8, August 1921, pp. 498–505. Abstract of recent report of committee of American Society for Testing Materials covering steel rails, steel pipe, boiler and superheater tubes.

Tool. The Oxidation of Carbon Tool Steel on Heating in Air, Howard Scott. Chem. & Metallurgical Eng., vol. 25, no. 2, July 13, 1921, pp. 72–74, 9 figs. Results of experiments show that below 850 deg. cent. and for period up to five hours there is no appreciable decarbonization—that is, scaling at least keeps space with decarbonization.

[See also MOLYBDENUM STEELS; NICKEL STEEL; STEEL, HIGH-SPEED; STRUCTURAL STEEL.]

STEEL CASTINGS

Centrifugally Cast. Tests of Centrifugally Cast Steel, George K. Burgess. Techn. Papers Bur. Stand., no. 192, 22 pp., 9 figs. Six castings were examined as to their physical and chemical properties, showing the possibility of substituting heat treatment for forging in this type of casting.

Green-Sand. Steel Castings Made in Green Sand, W. H. Roesner. Foundry, vol. 49, no. 14, July 15, 1921, pp. 552–554, 5 figs. When proper precautions are observed steel castings poured in this medium are said to present as pleasing an appearance as any gray iron or malleable castings.

STEEL, HEAT TREATMENT OF

Factors Governing. Factors Governing the Production of Heated Products, J. A. Brown. Trans. Am. Soc. Steel Treating, vol. 1, no. 10, July 1921, pp. 575–587. Summary of factors to be considered.

STEEL, HIGH-SPEED

Manufacture. The Manufacture of High Speed Steel, Felix Kremp. Official Proc. Central Ry. Club, vol. 29, no. 3, May 1921, pp. 1042–1046 and (discussion) pp. 1046–1051. Details of manufacture.

STEEL WORKS

England. The New Darnall Works of Messrs. Davy Brothers, Limited. Iron & Coal Trades Rev., vol. 102, no. 2782, June 24, 1921, pp. 841–843, 5 figs. Details of new works for manufacture of steelworks plant and boilers, the Davy patent high-speed forging press, modern rolling-mill plant, and accessories.

Power Plant for. Modern Steel Works Power Plant, W. N. Flannigan, Part III. Blast Furnace & Steel Plant, vol. 9, no. 8, August 1921, pp. 510–514. Considers the questions of efficiency and possibilities of saving.

STRUCTURAL STEEL

Plant. Design of Structural Steel Plant of 5000-Ton Capacity, W. D. Coulter. Can. Engr., vol. 41, nos. 2 and 3, July 14 and 21, 1921, pp. 7 and 11 and 9–10, 5 figs. Layout of plant and buildings; types of buildings and equipment.

SUPERHEATERS

Marine and Locomotive. Superheaters and Fuel Economy—XII. Machy. Market, no. 1078, July 1, 1921, pp. 21–22, 3 figs. Marine and locomotive superheaters.

Performance. Superheaters and Superheat, A. D. Pratt. Mech. Wld., vol. 70, no. 1803, July 22, 1921, pp. 61–63. Discusses safety-valve equipment, superheater performance and variable combustion conditions.

SWAGING MACHINES

Band-Saw. Swaging and Side-Dressing Machine for Band Saws. Engineering, vol. 112, no. 2900, July 29, 1921, pp. 186 and 188, 9 figs. Machine constructed by A. Ransome & Co., Ltd., Newark-on-Trent, England, can deal with saws from 3½ in. to 8 in. wide and with teeth from 1¼ in. to 2½ in. pitch. It is entirely automatic in operation and works at rate of 20 teeth a minute.

T

TAR OILS

Low-Temperature. Uses for Low-Temperature Tar Oils, F. P. Coffin. Gas Age-Rec., vol. 48, no. 3, August 6, 1921, pp. 97–100, 5 figs. Considers creosote and light motor fuel oils.

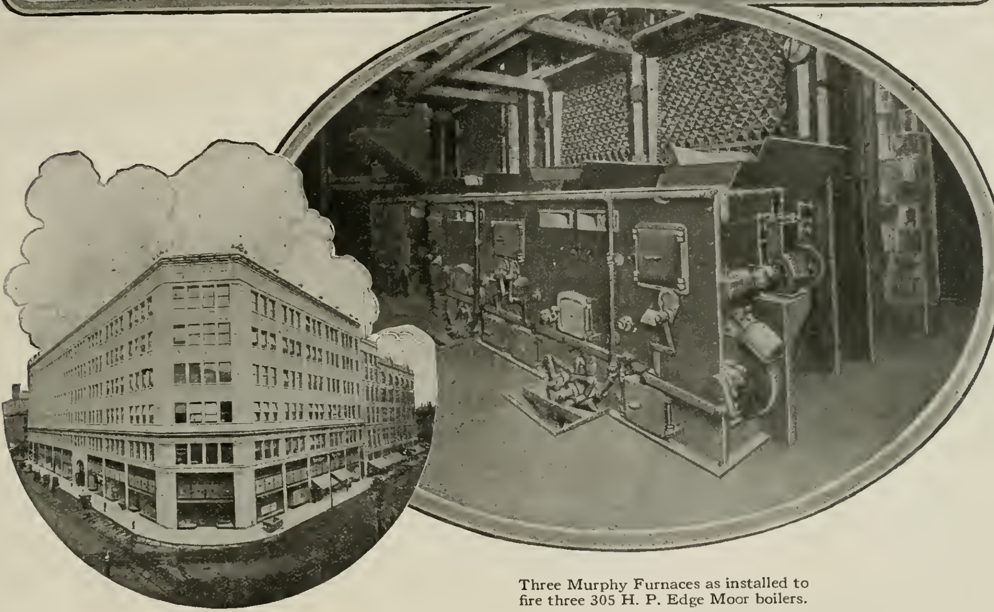
TEMPERATURE MEASUREMENT

Instruments for. The Measurement of Temperature—XII, P. Field Foster. Mech. World, vol. 70, no. 1801, July 8, 1921, pp. 32–33, 6 figs. Details of Carpenter-Stansfield deflection potentiometer; and thermocouple indicator made by Foster Instrument Co. Describes several industrial applications of thermocouple pyrometers and methods of mounting. (Continuation of serial.)

TESTING MACHINES

Bar. Testing Machine Helps, R. W. Allard. Iron

221 MURPHY FURNACES INSTALLED IN 72 OFFICE BUILDINGS



Three Murphy Furnaces as installed to fire three 305 H. P. Edge Moor boilers.

For office buildings the first requirement for stoking equipment is that it must not emit black smoke through the chimney nor obnoxious gases in the boiler room to circulate up through the building.

St. Paul's newest and finest office building, the Hamm Building—in selecting

MURPHY AUTOMATIC FURNACES

for their power purposes is assured that the above requirement will be met.

Here's the process that makes the Murphy smokeless. As the coal enters the furnace it rests for a short time on the coking plate. There the volatile gases are driven off and immediately mixed with the heated air admitted through the arch plate air ducts, forming a combustible gas which is burned as it passes toward the rear of the furnace. The fuel travels slowly down the inclined grates toward the clinker grinder, receiving the requisite amount of air through the grates to complete the burning process.

221 Murphy Furnaces installed in *72 office buildings*, a total of *36,679 B. H. P.*, indicate that they have *made good* in this field.

If saving 15 to 30% of your coal bill interests you along with other advantages, write today for Catalog A-10

ENGINEERING INDEX (Continued)

Age, vol. 108, no. 2, July 14, 1921, p. 87, 1 fig. Compiling table to translate pounds on test bar into pounds per square inch.

Brinell Hardness. The Brinell Test. Machy. (Lond.), vol. 18, no. 459, July 14, 1921, pp. 459–461, 3 figs. Describes two new machines, a power-operated hardness and a small ball hardness testing machine.

The Brinell Testing Machine. Some of Its Uses, Alfred Herbert. Can. Machy., vol. 26, no. 1, July 7, 1921, pp. 75 and 76. Points out advantage of its use for very soft steels, case-hardening steels, non-ferrous alloys, etc.

TEXTILE INDUSTRY

Felt-Manufacturing Machinery. True or Pressed Felt Manufacturing, J. A. Butler. Textile World, vol. 60, no. 3, July 16, 1921, pp. 27–29, 3 figs. Particulars of machines and processes employed.

Winding and Warping Machinery. New Winding and Warping Machinery. Textile World, vol. 60, no. 3, July 16, 1921, pp. 33 and 59, 5 figs. Yarn wound into large cheeses; warping speed 500 to 600 yards per minute. Automatic features.

TEXTILE MILLS

Steam Plant. The Hamilton Plant of the Canadian Cottons Ltd., T. H. Fenner. Power House, vol. 14, no. 14, July 20, 1921, pp. 21–25, 7 figs. Steam plant installed to supply steam for process work and heating.

Ventilation. The Ventilation and Humidification of Textile Factories, H. N. Leask. Engineering, vol. 112, no. 2900, July 29, 1921, pp. 202–204, 2 figs. Describes apparatus designed by A. B. Cleworth to meet all requirements of constancy of humidity and ventilation, etc. Presents chart showing average monthly temperatures in weaving shed. Paper read before Rochdale Cotton Spinners' Mutual Improvement Soc.

THERMIT WELDING

Pipe Joints. Thermit Welded Pipe Joints, R. L. Browne. A.S.R.E. Jl., vol. 7, no. 6, May 1921, pp. 452–457 and (discussion) pp. 457–459, 4 figs. Gives results of tensile and bursting tests, and vibration tests.

THERMODYNAMICS

Definition. Critical Discussion of the Traditional Definition of Thermodynamics (Kritische Betrachtungen zur traditionellen Darstellung der Thermodynamik), M. Born. Physikalische Zeit., vol. 22, nos. 7, 8 and 9, Apr. 1, 15 and May 1, 1921, pp. 218–224, 249–254 and 282–286, 3 figs. Deals with work by C. Carathéodory entitled Investigations of the Fundamental Principles of Thermodynamics, published in Math. Annalen (vol. 61, p. 355, 1909), of which, author claims, too little is known among physicists. Points out importance of work for explaining fundamental conceptions and as a basis for instruction.

TIDAL POWER

France. Project For Utilizing the Tides in the Bay of Rothéneuf [Project of Utilisation des Marées dans la Baie de Rotheneuf (Ille-et-Vilaine)], Ch. Dantin. Le Génie Civil, vol. 79, no. 5, July 30, 1921, pp. 102–106, 9 figs. Discusses tide conditions and proposed turbo-alternator equipment, cost of power, etc.

Utilization. Utilizing the Power of the Tides (Utilisation de l'Énergie des Marées), M. Boisnier. Annales des Ponts et Chaussées, vol. 62, 11th Series, May-June 1921—III, pp. 297–396, 13 figs. Discusses means and methods of accumulating and using the power, also in connection with railway electrification.

Industrial Use of the Power of Tides (L'Utilisation Industrielle de la Force des Marées), Henri Fischer. Bulletin de la Société Industrielle de Mulhouse, vol. 87, no. 3, Mar. 1921, pp. 169–181, 3 figs. Describes the Parisot system.

TIMBER

Waste Elimination. Industrial Timber Research Abroad and In South Africa, Nils B. Eckbo. So. African Jl. Ind., vol. 4, no. 6, July 1921, pp. 534–539, 6 figs. Concentrates on elimination of wastes and improved utilization of forest products.

TIME STUDY

Watch for. Time Study Watch That Records Number of Operations Performed in One Hour. Coal Age, vol. 20, no. 2, July 14, 1921, p. 52, 1 fig. Describes new duration time-study watch for timing, analysis and observation of from one to ten operations up to including five minutes of duration.

TIRES, RUBBER

Durability. Determining Factors for the Life of a Pneumatic Tire, William G. Nelson. Chem. & Metallurgical Eng., vol. 25, no. 4, July 27, 1921, pp. 153–154. Discusses five factors, namely, rubber and compounding materials, fabric, construction, vulcanization and usage. Causes for premature failures of tires.

Fabric for. A Brief Analysis of Tire Fabric Manufacture, H. R. Whitehead. India Rubber World, vol. 64, no. 5, August 1, 1921, pp. 814–816, 10 figs. Discusses picking, carding, combing, drawing, slubbing, warping and twisting, weaving.

Pneumatic. Dynamic Balance and Construction of the Pneumatic Tire, William Roberts. India Rubber World, vol. 64, no. 5, August 1, 1921, pp. 811–813, 9 figs. Considers variables in tire construction, proper bead location, assembling threads and gives a formula for figuring weight of cured and uncured thread.

The Determining Factors for the Life of a Pneumatic Tire, William G. Nelson. India Rubber World, vol. 64, no. 5, August 1, 1921, pp. 806–808. Considers the five factors, rubber and compounding materials, fabric, construction, vulcanization and usage.

TOOLROOMS

Puget Sound Navy Yard. Caring for Tools at Puget Sound Navy Yard. Am. Mach., vol. 55, no. 3, July 21, 1921, pp. 94–96, 7 figs. Central tool-grinding room. Novel system of sliding racks for storing milling cutters. Cleansing and lubricating pneumatic tools.

TRACTORS

Caterpillar. Tractors in the Oil Fields, Earle W. Gage. Oil Field Eng., vol. 23, no. 7, July 1921, pp. 66, 1 fig. Gives particulars of successful application of caterpillar type of tractor.

Lubrication. Tractor Lubrication, J. W. Stack. Part II. Sci. Lubrication, vol. 1, no. 6, June 1921, pp. 9–14, 12 figs. Discusses lubrication as applied to internal-combustion-motor-propelled units. (Concluded.)

TRAILERS

Clay-Products Industry. Use of Trailer Saves Motive Power, Gilbert I. Stodola. Brick & Clay Rec., vol. 59, no. 1, July 12, 1921, pp. 35–38, 6 figs. Application of trailer and semi-trailer in clay-products industry for distribution of clay ware.

TRUSSES

Stress Determination. Theory of Structures, Ernest W. Dibley. Commonwealth Engr., vol. 8, no. 11, June 1, 1921, pp. 328–329, 9 figs. Describes a method for determining by inspection the nature of stresses in the members of trusses for dead and uniformly distributed live loads.

TUBES

Seamless. On the Manufacture of Seamless Tubes—IV, Karl Gruber. Blast Furnace and Steel Plant, vol. 9, no. 7, July 1921, pp. 442–444, 6 figs. Seamless tube rolling in Germany, with special consideration of Mannesman pilgrim-step rolling mill.

U

U. S. BUREAU OF STANDARDS

War Work. War Work of the Bureau of Standards, U. S. Dept. of Commerce Bur. of Standards, no. 46, Apr. 1, 1921, 299 pp., 35 figs. Short descriptions of more important work carried on during war which was of direct service to military forces. Deals with aeronautic instruments and power plants; aircraft construction, materials, etc.; chemical investigations; coke-oven investigations; concrete ships; electric batteries; electric tractors and trucks; precision gages; illuminating engineering; invisible signaling; magnetic investigations; metallurgical investigations; natural-gas investigations; optical glass and instruments; protective coatings; radio communication; radium; rubber; searchlights; sound-ranging apparatus; wheels; X-rays, etc.

V

VIBRATION

Measurement. Measurement of Vibration of the 660-ft. Wireless Telegraph Station Tower at Haranomachi, F. Omori. Engineering, vol. 112, no. 2900, July 29, 1921, pp. 196–199, 13 figs. Results of measurement of movement of tower caused by winds carried on during course and after completion of construction on five different occasions.

VISCOSITY

Effect on Orifice Flows. The Effect of Viscosity on Orifice Flows, W. N. Bond. Physical Soc. Lond. Proc., vol. 33, part 4, June 15, 1921, pp. 225–230, 2 figs. Results of determinations are plotted in manner which combines both purely viscous and purely turbulent flows in one graph. It is shown that effect of slight viscosity is to increase coefficient of discharge.

W

WAGES

Incentive vs. Production Basis. Incentive or Production Basis of Wage Payment—I and II, Henry Farquhar. Am. Mach., vol. 55, nos. 5 and 7, Aug. 4 and 18, 1921, pp. 169–172 and 275–277, 1 fig. Aug. 4: Constructive preparation necessary; effect of working conditions on mental attitude; elements of scientific management; determining standard production time. Aug. 18: Reward for standard accomplishment; variations in types of incentive; aristocracy of skilled labor; individual and group reward.

Wage-Level Formula. Past and Future Wage Levels, Halbert P. Gillette. Eng. & Contracting, vol. 56, no. 5, August 3, 1921, pp. 97–101, 2 figs. Develops a wage-level formula for which he concludes that during the past 30 years the per capita bank deposits have increased twice as rapidly as per capita money.

WAR DEVASTATION

Metallurgical Works, France. Destruction of the Works of the Compagnie Métallurgique Franco-Belge at Mortagne (La Destruction des Usines de la Compagnie Métallurgique Franco-Belge de Mortagne), Marchal. Révue de Métallurgie, vol. 18, no. 5, May 1921, pp. 261–263, 4 figs.

Destruction of French Metallurgical Works by the Germans During the War (Les déprédations et destructions commises par les Allemands aux Usines de Givet de la Compagnie francaise des Métaux pendant la guerre de 1914–18), A. Mercier des Rochettes. Révue de Métallurgie, vol. 18, no. 5, May 1921, pp. 247–259, 17 figs.

WASTE HEAT

Utilization. The Utilization of Waste Heat in Gasworks, George E. Stewart. Engineering, vol. 112, no. 2897, July 8, 1921, pp. 77–78. Notes on carbonization, water gas manufacture, and waste heat boilers. Paper read before Instn. Civ. Engrs.

WATER

Viscosity. Viscosity of Water at Low Rates of Shear, Albert Griffiths. Physical Soc. Lond. Proc., vol. 33, part 4, June 15, 1921, pp. 231–242, 4 figs. Determination by method in which water is forced along glass capillary tubes of about 1.5 to 2 mm. bore at rates of flow varying from 1 liter in two years to 1 liter in 24 years.

WATER POWER

Canada. Available Water Power in Canada. Can. Engr., vol. 41, no. 1, July 7, 1921, p. 1. Figures recently compiled by Dominion water-power branch.

Development. Water Power Development, W. E. Williams. Beama, vol. 9, no. 1, July 1921, pp. 19–24, 7 figs. Notes on survey of a catchment area; artificial reservoirs; and linking up of hydroelectric stations.

Germany. The Development of German Water Powers (Der Ausbau unsrer Wasserkräfte). Zeit. des Vereines deutscher Ingenieure, vol. 65, no. 26, June 25, 1921, pp. 687–697, 3 figs. Notes on developments in Bavaria, Southwest Germany, Harz and Silesia. Water power in France.

Montana. Hydro-Electric Possibilities in Montana, E. W. Kramer. Elec. World, vol. 78, no. 3, July 16, 1921, pp. 111–115, 5 figs. Total water power available placed at approximately 1,000,000 hp., of which 225,000 hp. has been developed. Study of four principal watersheds showing possible developments of over 10,000 hp.

Rhone River. Utilization of the Water Power of the Rhône (L'aménagement des forces motrices du Rhône), L.-D. Fourcault. L'Electricien, vol. 52, no. 1280, July 15, 1921, pp. 313–314, 1 fig. Details of project recently adopted.

Undeveloped. Probable Water-Power Developments. Elec. World, vol. 78, no. 5, July 30, 1921, pp. 219, 6 figs. Tabulation of the undeveloped water powers of over 10,000 hp. by drainage basins.

Utilization. Contribution to the Study of the Determination of the Hydraulic System of a Basin in Terms of Its Rainfall. (Contribution à l'étude du ruissellement et à la détermination du régime hydraulique d'un bassin en fonction de sa pluviosité), Aimé Coutagne. Revue Générale De L'Electricité, vol. 9, no. 25, June 18, 1921, pp. 885–893, 5 figs. Technical study. Application of conclusions derived from central region of France. (To be continued.)

The Employment of Water Power in the Development of the Mineral Industry, John Evans. Engineering, vol. 112, no. 2897, July 8, 1921, p. 76. Past developments and future possibilities. Paper read before Instn. Civ. Engrs.

Steam-Condensing Plants

A Detailed Consideration of the Fixed and Operating Charges in Surface-Condenser Installations, and Description of a New Type of High-Efficiency Condenser

By PAUL A. BANCEL,[1] NEW YORK, N. Y.

THE heart of a power plant lies in the boiler room, and the most important aspect of the condensing plant is in its relation to boiler-room costs. The choice of a condenser may be said to rest largely on its influence in reducing boiler-room charges. As indicated in Fig. 1, it would pay to run condensing if coal cost nothing; and pay even more, if the boiler feed was poor or expensive, to install the costliest of condensers—the surface type. With pure feedwater there is less fuel loss and boiler-maintenance charges, and, what is of still greater importance, boilers may be driven at higher ratings with consequent further reductions in first costs and fixed charges.

The designer of a power house is in a quandary—flying from boiler evils to condenser evils, and often with hesitancy as to which are the less serious. The problem is one of balancing fixed and operating charges in the boiler room against similar charges in the condensing plant.

Fixed Charges

The fixed charges against a surface-condensing plant depend on—

a Vacuum desired, which influences the size and cost of the equipment

b Cost of tube replacement, which depends on amount of tube surface in any particular design and life of the tubes as influenced by water conditions and condenser design

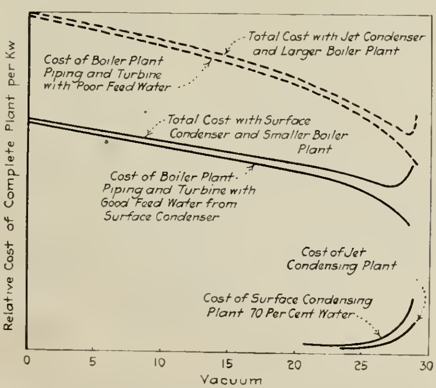

Fig. 1 Relative First Cost of Steam Power Plant at Different Vacuums

c Power for the auxiliaries, which increases if the cost and fixed charges are reduced.

Vacuum. In Fig. 2 the curve 0-0-0 shows the absolute back pressures at the turbine exhaust which might be expected from a cycle of water temperatures and a certain investment in condenser. Frequently the design of the turbine is such and the water temperatures in the winter are so low that for certain winter periods a vacuum is obtained which is better than can be utilized by the turbine. On the other hand, the temperature of the available water supply for three to six months of the summer is 60 to 80 deg., so that the vacuums obtainable are lower than are desirable for maximum turbine economy. Area *C* in Fig. 2 indicates the range of vacuums by investing more or less money.

As will be seen later, extensive calculations in regard to best investment are apt to be misleading because of the reduction in vacuum which so often occurs due to fouling of the tubes. In such instances all other questions become subordinate to that of maintaining high vacuum continuously, under actual operating conditions. In other cases the decision must rest on the relation

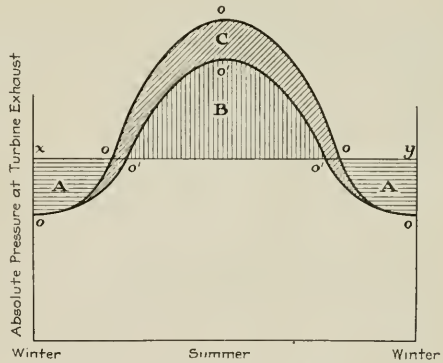

Fig. 2 Cycle of Absolute Back Pressure of Year

Line *x*–*y* represent highest vacuum or lowest desirable exhaust pressure. Areas *A*,*A* represent waste in winter due to excessive vacuum and areas *B* and *C* waste in summer due to warm water and insufficient vacuum. Area *C* indicates improvement possible by investing more money.

of load factor, months of the year having hot water and the fixed charges and operating charges at different vacuums.

Cost of Tube Replacement. This can be set up as a yearly depreciation reserve. The life of a condensing plant might be 20 years, whereas the tube life might be only five. On a 10,000-kw. turbine this might necessitate the purchase every five years of tubes costing about $10,000. Thus in determining the best vacuum the item of tube renewals may have a preponderating influence. Furthermore, as between two condensers for the same vacuum, one of which requires less tubes than the other, it is manifest that the fewer the tubes the less the fixed charges.

Similarly, the longer the tube life the smaller the fixed charges and cost of power. In one plant the tube life might be five years and in others a great deal more or a great deal less. Tube life depends on the character of the water supply, on the chemical, physical and metallographic properties of the tubes (crystalline structure) and it also depends on the design of the condenser. The latest report of the Corrosion Committee of the Institute of Metals, London, summarizes the types of condenser-tube corrosion, principally general thinning, pitting and apparent dezincification. The fourth and fifth reports of this Corrosion Committee are exhaustive studies of the subject, and among other causes

[1] Ingersoll-Rand Company, New York, N. Y., Jun. Am.Soc.M.E.

Presented at a meeting of the Baltimore Section of The American Society of Mechanical Engineers, May 16, 1921. Slightly abridged.

emphasize the effect on corrosion of low velocity and high temperature.[1]

Velocity has a direct effect on corrosion. Low velocity allows the deposit of foreign matter in the tubes which forms obstructions around which the products of corrosion accumulate in concentrated form, with the resultant pitting. High water velocity keeps the tubes clean and eliminates this form of corrosion.

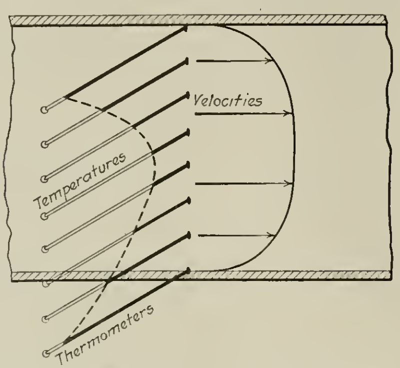

Fig. 3 Influence of Water Velocity and Tube Diameter on Temperature Distribution

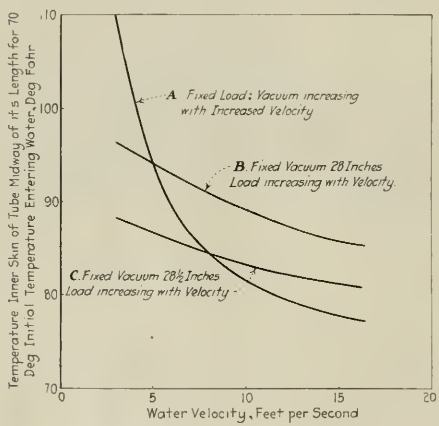

Fig. 4 Relation of Skin Temperature to Water Velocity at Different Loads and Vacuums

High temperature accelerates corrosion of all types and so seriously that a temperature of 95 deg. fahr. is recommended as the maximum. There are three ways of reducing temperatures in order to alleviate corrosion: by increasing the water quantity, thus decreasing the overall rise; second, by eliminating hot spots and local overheating of tubes; third, by increasing water velocity or decreasing tube size, thus decreasing the skin temperature at the tube wall. The first of these needs no comment. As to the second, it is well known that faulty steam distribution causes excessive heating of the water in some tubes counterbalanced by practically no heating of other tubes. Thus in condensers in which the steam distribution is obtained by lanes, the tubes in the path of the steam heat the water rapidly, but they short-circuit the tubes within the banks. The short-circuited tubes are not only wasted surface, but are the cause of the excessive temperatures in the exposed tubes, which consequently corrode rapidly.

The third method of reducing temperature, higher velocity and smaller tube size, may need explanation. It is well known that more heat is transferred for a fixed area of tube surface and fixed conditions of steam temperature and water temperature, if water velocity is increased or tube diameter reduced. The tube acts as though a colder water supply were being used, and this is exactly what is happening because the water at the walls is really colder. The metal is therefore colder and can abstract more heat in the same time from steam at the same temperature.

The flow of water in a tube is accompanied by cross-currents and whirls which convey the heat from the walls into the body of the water. In Fig. 3, if thermometers were placed as indicated the temperature readings would follow a curve as shown. Increased velocity reduces the temperature at the walls, making the curve flatter. Similarly, using a smaller tube reduces the temperature at the walls and makes the temperature gradient flatter. The inner skin temperature may be approximated from

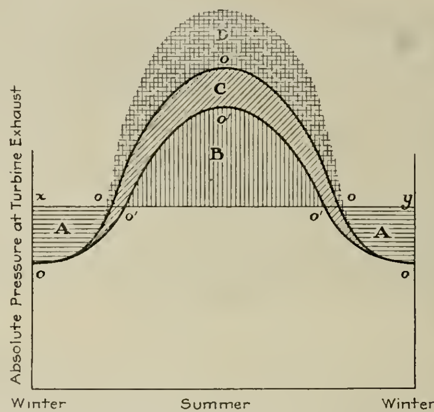

Fig. 5 Cycle of Absolute Back Pressures at Different Seasons
Area D shows increased back pressure or loss of vacuum due to fouling.

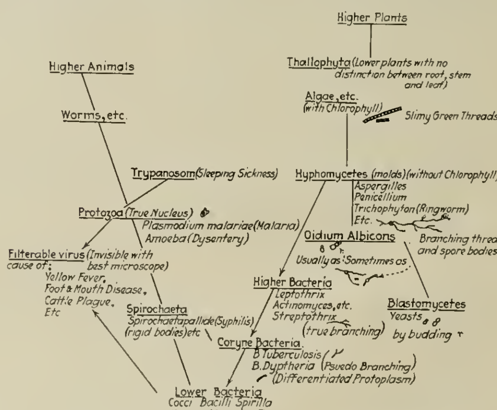

Fig. 6 Forms of Life in Condenser-Tube Slime

various experimental results on heat transmission and curves obtained as in Fig. 4, which shows the relation between the water velocity and this inner skin temperature for conditions of constant load (Curve A) and constant vacuum (Curves B and C). In all cases increasing the velocity reduces this temperature.

In a condenser with proper distribution to avoid hot spots, and with suitable velocity and tube diameter to further reduce skin temperature and prevent foreign deposits, a markedly longer life of tubes will be obtained. As will be seen, too, these features of design result in small initial surface requirements, so that there is a twofold reduction in the fixed charges to take care of replacements.

[1] Jour. Inst. of Metals, vol. 23, p. 76.

Operating Charges

The principal operating charges on a condensing plant may be grouped as follows:

a Reduction of condensate temperature below steam temperature and consequent loss of coal

b Power for operating the auxiliaries

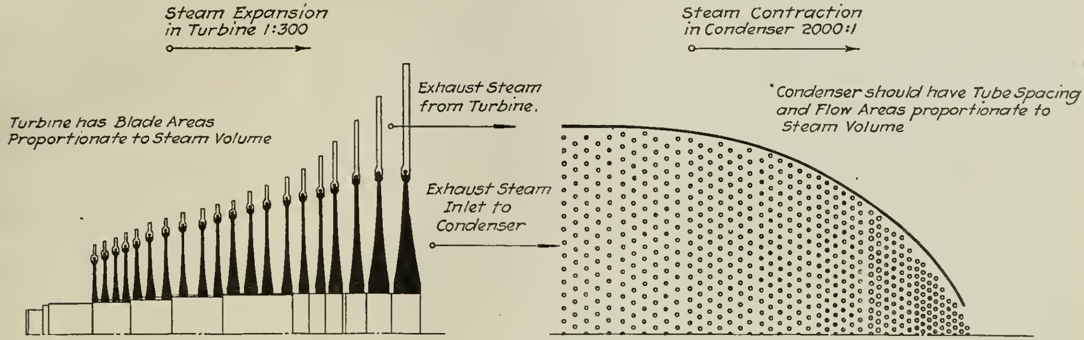

Fig. 7 Comparison of Steam Flow in Turbine and Correctly Designed Condenser

c Reduction of vacuum and increased coal consumption due to scaling and sliming of the tubes

d Cost and time lost to clean the tubes and cost and time lost due to tube failure and consequent pollution of the boiler feed.

Reduction or Depression in Condensate Temperature below steam temperature depends on condenser design and temperature of circulating water, being less with warm water and greater with

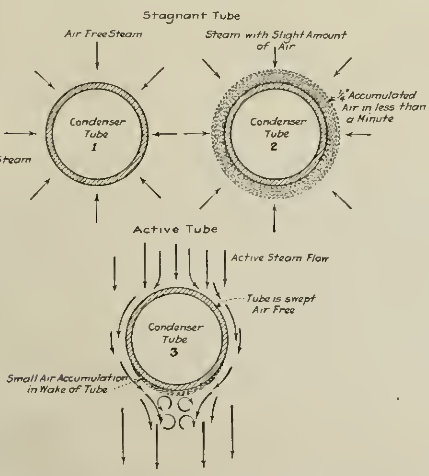

Fig. 8 Importance of Steam Velocity in Preventing Stratification of Air around a Condenser Tube

Stagnant Tube: Condition when steam flow is produced by avidity of tube itself for condensing steam.

Active Tube: Condition when there is active steam flow to sweep tube free of air.

cold water. The water of condensation must fall over successive rows of tubes to reach the bottom and if the steam is not drawn down to the bottom of the condenser, the water will be gradually cooled. The colder the water and higher the vacuum the greater the proportion of idle surface and the colder the condensate. Even in those condensers, in which numerous short-circuiting lanes are provided for the express purpose of securing penetration of the steam, there is a depression of condensate temperature of 5 to 10 deg. in summer and 10 to 20 deg. in winter. Eleven degrees loss of condensate temperature represents 1 per cent loss of efficiency and is equivalent to 300 kw. on a 30,000-kw. machine. In some plants this loss is largely overcome by the installation of preheaters.

Power for Operating the Auxiliaries has already been considered in a sense in the discussion of fixed charges, since the power required for any vacuum is partly dependent on the investment, and may

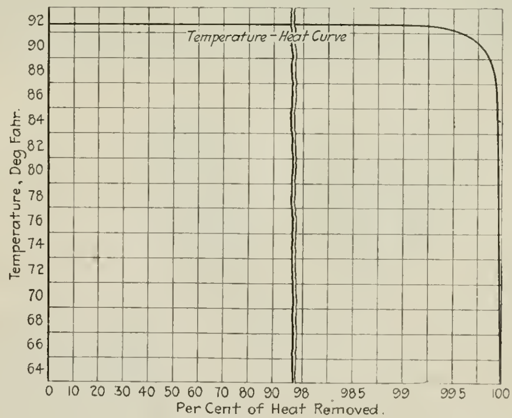

Fig. 9 Relation between Percentage of Heat Removed from a Mixture of Steam and Air and Temperature of the Mixture

Note scale is magnified 40 times at right-hand section of chart for the assumed mixture which is a fair average in high-vacuum condensers; the temperature starts to fall at 99 per cent.

be decreased by increasing the investment and fixed charges. No distinction should be made between the power required for driving condenser auxiliaries and the main power output of the plant, even where the auxiliaries are steam-driven and exhaust to a feed heater. The auxiliary power is a direct charge against the main unit output.

The principal item of power consumption lies in the circulating pump, and this unit is often arranged for variable-speed drive or else is divided into two smaller units, so that with cold water or light load the operating charge may be reduced by slowing down or by shutting down one pump. As shown in Fig. 2, an excessive vacuum is obtainable in the winter and the waste of fixed charges can be partially offset by saving on the circulating-pump power.

The best balance of circulating-pump power in the summer time for conditions of maximum water temperature and full load must be settled after consideration of all the aspects of the problem. By proportioning the condenser for low water velocities the head on the circulating pump may be made low, and the quantity of water used very low with small power requirement for driving the pump. This saving, however, may be counterbalanced by

excessive fixed charges distributed over a relatively small part of the year. Thus suppose the investment were increased $5,000 on a 10,000-kw. unit, and the circulating-pump power reduced by 50 kw. The added fixed charges including tube renewals might be $1000 per year, and if this be charged against the summer months, the rate might be 50 cents to several dollars per hour depending on the number of hours. This would offset 50 kw. For this reason many plants use two pumps in the summer, working under relatively high heads of 30 to 40 ft.

Low pump power with low water velocities may be offset also by increased operating charges due to low vacuum resulting from fouling. Fig. 5 is similar to Fig. 2, except that a shaded portion *D* has been added to indicate the range of vacuum in the summer time under actual conditions of fouling of condenser tubes. As much as an inch of vacuum is lost in a week in some cases, and in one extreme instance there is a loss of an inch in two days. It is unfortunate that the loss by fouling is most severe in the summer when it is most difficult to obtain high vacuum. As a reduction of only $^1/_4$ in. in vacuum represents a loss of $1^1/_2$ to 2 per cent of turbine economy, which may be equivalent to all the auxiliary power, it is readily seen how easily all calculations of exact balance between fixed charges against the condenser and operating charges against the auxiliaries may be disrupted.

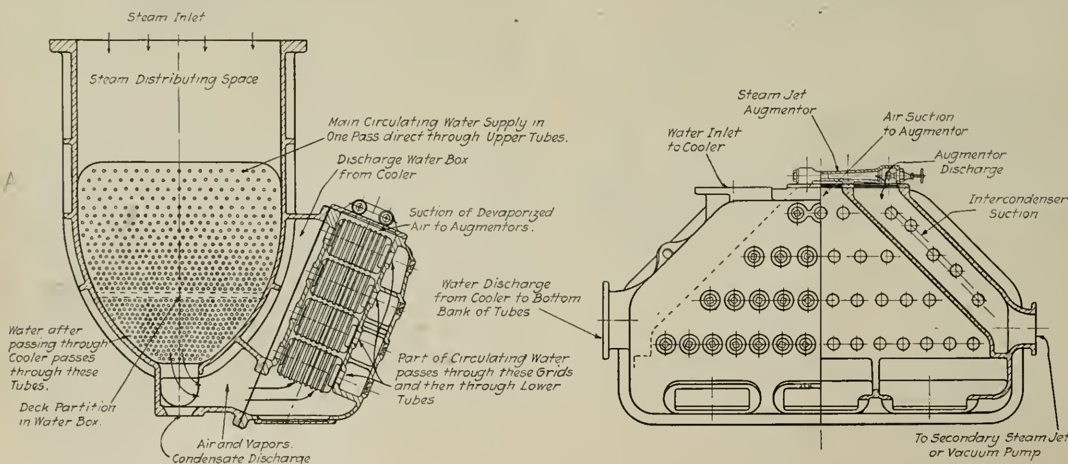

Fig. 10 Cross-Section through Main Condenser and Cooler of Ingersoll-Rand Surface Condenser

Reduction in Vacuum Due to Tube Fouling. The foreign matter that accumulates in condenser tubes may be divided into three classes:

a Mechanical deposits, silt and mud
b Scales deposited out of solution
c Slimes or organic growths.

The first of these is of minor influence in reducing vacuum unless water velocities are low indeed. The ability of a stream of water to carry solid substances in suspension increases rapidly with increase of the velocity. However, foreign matter such as silt, may be deposited in slime coatings which form a more adherent surface than a clean condenser tube.

The second form of deposits is common with salt water and hard waters carrying scale-forming salts, familiar in impure boiler feedwater. In many cases with cooling towers or spray ponds the source of make-up is a relatively hard water and causes deposits of sludge and scales in the condenser tubes. The commonest ingredients of such water are calcium and magnesium carbonate which are soluble in the presence of carbon dioxide. Heating the water drives off the CO_2 and precipitates the carbonates.

The influence of uniform steam distribution, smaller tube size and high water velocity on reducing skin temperatures has already been shown. It is also probable that high velocity has a mechanical effect in reducing the rapidity of such scale formations. In sugar evaporators it is commonly found that the tubes which work actively and therefore contain rapidly rising currents of mixed vapor and juice, scale the least; whereas tubes doing less evaporation foul more heavily.

Where extremely hard waters are encountered it is desirable not only to keep down the temperatures by observing the principles of high skin velocity and activity, but also by using larger quantities of water and smaller overall temperature rise. In this way it is possible as between two condensing plants to reduce the maximum temperature rise of the skin of water in the hottest tubes, 10 or 20 deg., or even more.

Slimes or organic growths are the third form of deposits. Fouling of this character is most severe in the summer time, and is also most severe in hot portions of a condenser with improper steam distribution. Thus, in a condenser with lanes, the tubes in the lanes will be found coated with a thick, heavy slime in a short time, whereas tubes in the short-circuited regions will be but slightly fouled. It is probable that these slimes are organic growths occurring under the ideal conditions of warmth and stagnation existing at the inner skin of the tube. A typical sample of condenser-tube slime was taken a short time ago by the author and given to a bacteriologist for analysis. A large number of hyphomycetes were demonstrated. This form of life is classified between bacteria and plants, as shown in Fig. 6. The hyphomycetes grow rapidly as long microscopic threads (Mycelia), which branch rapidly, forming a dense interlacing network in which all other organic and inorganic elements are caught. They grow better in an acid than an alkaline medium. The hyphomycetes are familiar to us as molds and fungi and are a form of life just below the algæ, which are the green slimes frequently seen in stagnant pools. The algæ contain chlorophyl and require light for their growth, whereas the hyphomycetes grow in the dark. The conditions for rapid growth are moisture, stagnation and a fair warmth. The optimum temperature is between 20 and 40 deg. cent. (68–104 deg. fahr.); when spores are formed they are more resistant to higher temperatures.

There are cases on record of two condensers side by side, one with low velocity the other with high velocity, in which the latter remains cleaner for longer periods. Similarly it is well known that condensers do not lose as much vacuum or have to be cleaned as frequently in the winter as in the summer, and also that those parts of the condenser that are hot foul more rapidly than those where the water is not heated. In one instance a condenser is so large that it is cleaned only part at a time, and when this practice was initiated the operating force found that cleaning the two lower quarters and one upper quarter improved the vacuum very slightly, whereas cleaning the last quarter which was exposed to

the full activity of the steam brought the vacuum back to normal. In this section, the tubes exposed to steam are so heavily fouled that two men are needed sometimes to push the brushes through. The same arrangement of tubes top revent local overheating, and the use of high water velocities to reduce inner skin temperatures and increase the activity and counteract stagnation along the inner wall of the tube, may be expected, therefore, to reduce and eliminate the formation of organic slimes. Corrosion, scaling and sliming can all be reduced by correct proportion of a condenser for high activity of water flow and turbulence at the tube wall and uniform steam distribution, factors which in addition permit of a large reduction in the amount of tube surface.

Fouling adds to the operating charges in another way, as there may be a large labor cost for cleaning. The time loss with a unit out of service is also a considerable item of cost. The charges due to failure of tubes by splitting and corrosion are of a similar nature. The pollution of the condensate and consequent scaling of the boilers from either impure condensate or from raw feedwater adds to the operating charge in the boiler room. The loss of time on the complete power-generating unit required to shut down, locate, and plug the leaking tube adds to the turbine-room operating charges.

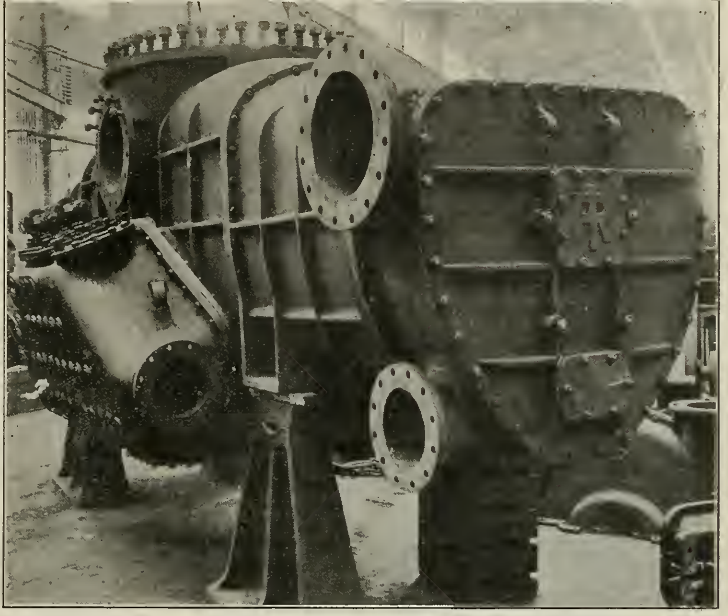

Fig. 12 Ingersoll-Rand Surface Condenser from Inlet Water-Box End
At the left is the cooler, mounted on shell.

Clogging of Tubes. One other loss adding to operating charge is that caused by clogging of tubes by accumulation of miscellaneous solid substances against the tube sheet. This applies only to plants using natural water supplies. With spray ponds the nozzles clog long before the condenser tubes. Clogging can be reduced by proper screening, and the use of flush, well-rounded tube inlets and high water velocities. Low velocities are wanted in the screens, but high velocities and clear inlets into the tubes. The influence of velocity is clearly shown by the tendency in two-pass condensers for the tubes of the return pass to clog with solid matter which originally came through the first pass. This clogging is most noticeable toward the top (where the water is needed most) and is due no doubt to the slow velocities at the top of the return box, which is at the top of the siphon and acts as a skimming tank.

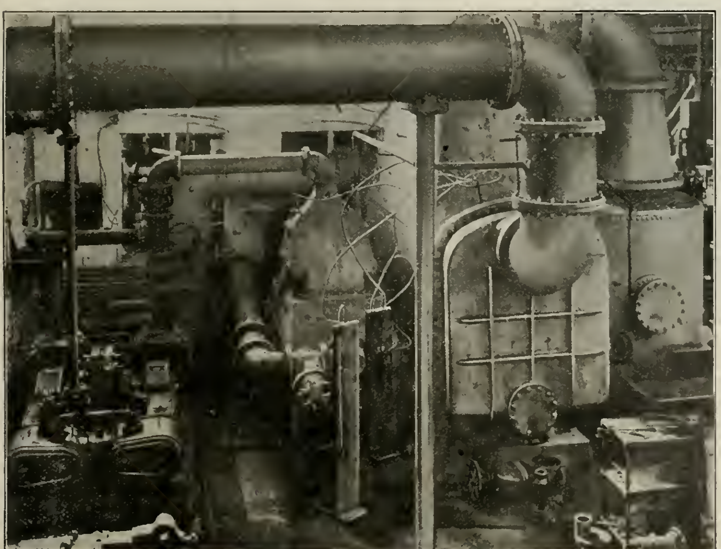

Fig. 11 Large Experimental Surface-Condenser Plant at Works of the Ingersoll-Rand Co., Phillipsburg, N. J.

Condenser Design

The design of a surface condenser to conform with the requirements which have been outlined, lies in the proper application of certain well-known principles. The first of these is to keep all of the tubes uniformly hot on the steam side so that the minimum number will be needed because none is wasted. To accomplish this the steam must be free to flow to all the tubes and over all the tubes, with slight loss of pressure and temperature, the condenser being arranged in stages, much as is a turbine, with large flow areas at the exhaust entrance and great distances between rows to avoid sharp bends and pressure loss. Fig. 7 illustrates the analogy.

Of equal importance in keeping all tubes hot is the proper staging to maintain velocities that will sweep the air ahead in the current of steam and the arrangement of tubes in staggered rows so that none is shielded or pocketed. Air left on a tube after condensation would otherwise stratify in a thick layer in a few seconds. With rapid steam velocities as shown in Fig. 8, all of the tube is hot because the air is continually carried away in the current of steam. Experiment has shown that this current is most active in producing heat transfer in front of the tube; the side about 90 per cent active, and the back about 75

per cent. This indicates the importance of a staggered tube arrangement so that the front of each tube is presented to the steam flow.

The steam velocities must be sustained throughout the depth of the condenser, which not only requires proper tube spacing but a shell of decreasing width—that is, a wedge- or heart-shaped shell terminating in a narrow, slot-shaped outlet. In this respect also the condenser is analogous to the turbine, Fig. 7, which has both changing blade height and changing wheel diameters.[1]

If the foregoing conditions are maintained, the mixture of steam and air is kept homogeneous and the temperature does not fall until a surprisingly large percentage of steam has been abstracted and the process almost completed. Fig. 9 shows the relation between percentage of heat removed from an average steam-air mixture such as would enter a condenser, and the temperature of the mixture. Starting with approximately 92 deg. temperature there is no perceptible fall of temperature due to increasing air richness until over 99 per cent of the heat has been abstracted and over 99 per cent of the steam condensed. Thereafter the temperature falls with a marked knee in the curve, the exact position and shape of which depend on the proportion of air to steam in the original mixture.

This process is *no longer rapid condensation but a matter of devaporization*, to reduce vapor temperature and pressure and increase partial air pressure so that the air may be removed by a vacuum pump. It is best carried out in a chamber external to the main condenser forming a devaporizer or cooler. Figs. 10, 11, and 12 illustrate such an arrangement in which the flow of hot vapors and air taken from the bottom of the main condensing chamber are turned upward into a cooler from which the concentrated air is finally removed at the top. It will be noticed that

Fig. 13 Showing Grids as Meshed when Assembled in Condenser Cooler

this cooler is also of wedge shape, decreasing in area as the outlet is approached. The air is withdrawn by steam-jet augmenters which discharge into an intercondenser section forming part of the cooler. The air at reduced vacuum is then withdrawn and compressed to atmosphere by secondary steam jets or a small reciprocating pump. In one case a single small pump is used as a secondary for two condensers, steam-jet secondaries being installed as stand-bys.

[1] Wedge-shaped shells have been in use for many years with Weir's marine condenser. The earliest record of this type of shell known to the author is that of its use 33 years ago by another English manufacturer.

The work of devaporization is done by cast-iron grids with fins, meshed together as illustrated in Fig. 13. Cold circulating water flows through the cores of the grids with only slight rise in temperature and then passes through the bottom group of tubes in the condenser (Fig. 10).

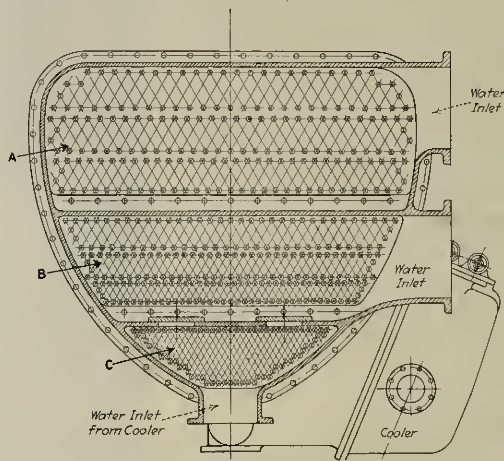

Fig. 14 Water Box with Two Injection Nozzles on I.-R. Surface Condenser

Both nozzles are used in summer, the upper one only in winter, thus obtaining high water velocity even with reduced water quantities and concentrating condensing action in top of condenser.

A large experimental plant, for capacities up to 70,000 lb. per hour was built at the Phillipsburg works of the Ingersoll-Rand Company to investigate these departures in design. The photograph reproduced in Fig. 11 illustrates the complete plant. By the use of electrical thermometers the performance of each row of tubes was determined and from that the efficiency of the tubes under all conditions of loads, vacuum and air leakage and in different parts of the condenser. A sliding or "trombone" thermometer of the electrical resistance type in the discharge water box was arranged so that it could be shifted to any position desired. Decks were fitted in the box which could be shifted to vary the water distribution so that a wide range of conditions of water circulation were obtained. It was found that high efficiency was obtained down to the last row of tubes of the condenser so long as certain critical conditions of vapor velocity were maintained. The condenser was hot throughout its depth and the condensate water at practically steam temperature. The hydrodynamic loss or pressure drop was also studied by the use of water manometers, from which the important relations of pressure loss, steam velocities, tube spacings, and number of rows were determined.

Depending on the air leakage, the cooler devaporizes and cools the air down as close to the temperature of the cold circulating water as one degree, thus giving complete countercurrent action. A study of these temperatures was made by electrical thermometers located at successive points as shown. As is well known from Dalton's law, the amount of air contained in a homogeneous flowing mixture of steam and air depends on the partial air pressure, which in turn depends on the temperature and corresponding partial vapor pressure, so that complete countercurrent action gives maximum withdrawal capacity of the vacuum pump and protection against excessive reduction of vacuum due to heavy air leakage.

It is evident that with the cooler taking care of the process at the knee of the curve and the main condenser hot and active throughout its depth, water cannot pass through great groups of tubes without heating, and therefore the entire bulk of the circulating water can be heated with only one passage through the tubes instead of multiple passes. The circulating water may be pumped, therefore, at low head and power consumption, with high average rate of condensation since none of the tubes is wasted, or

Fuel Saving in Modern Gas Producers and Industrial Furnaces

By W. B. Chapman,[1] New York, N. Y.

This paper calls attention to the wastes of fuel in the industries using gas producers and producer-gas furnaces. Both of these problems are in the field of combustion engineering.

The progress made in the last twenty-five years in gas-producer construction is emphasized by the descriptions of leading mechanical producers now in the market, together with an indication of their fuel-saving possibilities.

Attention is called to the savings made possible by using suitable accessories in the gas house.

To illustrate the possible savings in furnace operation a description is given of a distinctive type of recuperative furnace. The extension of the use of such a furnace to pulverized coal and oil would, the author states, result in similar savings.

There are about 10,000 gas producers in the United States. With the exception of the modern mechanical producer, most of these are "sick" and badly in need of a "gas doctor," and the furnaces they supply are in an equally bad way.

The producers in use are divided approximately as follows: 6500

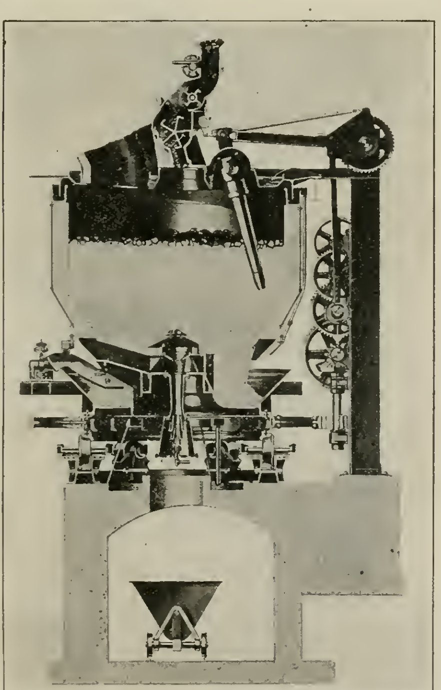

Fig. 1 Hughes Producer

in the steel industries; 1500 in the glass industries; 500 in the chemical industries; and 1500 in miscellaneous industries. Under "miscellaneous" are included the ceramic industries, lime burning and about 200 gas producers used for power.

Engineers have given much attention to the engine room, some to the boiler room, a little to industrial furnaces, and least of all to the making of raw producer gas. Hence the backward condition of the gas house.

No definite data have been compiled by the Government on the amount of coal used in gas producers, but with the assistance of such figures as are available it is estimated roughly that in the steel industries about 15,000,000 tons of bituminous coal are transformed annually into raw producer gas for use, and in the glass industries about 2,000,000 tons.

In the steel industries about the same amount of coal is used for making gas to heat furnaces as for making steam. In glass making three-fourths of all the fuel is used in gas producers. But wherever producer gas is used it is apt to be the most backward part of the business. A given amount of time and money, if spent on improving conditions in the gas house, will usually bring larger returns than in any other department. In most industries requiring large heating operations more trouble arises in that department than in any other part of the business.

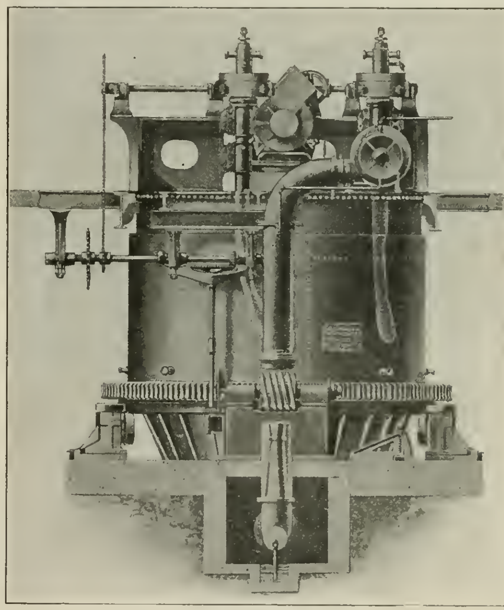

Fig 2 R. D. Wood Producer

Much progress has been made in the past 25 years in gas-producer construction. It started with the excellent work of W. B. Hughes. Progress in furnace construction, however, has lagged. The chief incentive to improvement of both producer and furnace has been high-priced labor, and the few advances made in furnace construction have been confined mostly to certain labor-saving features. Now the situation has changed; fuel saving has been put on a par with labor saving, and interest is being noted all along the line.

The Producer-Gas Process

In making producer gas there are three steps or operations: (1) Feeding the fuel; (2) agitating the fire; and (3) removing the ashes. Progress in producer construction has centered on various ways of performing these three operations automatically.

Automatic Coal Feeding, if continuous and uniform, will increase the B.t.u. in the gas about 10 per cent and will improve its uni-

[1] President, Chapman Engineering Company. Mem.Am.Soc.M.E.

For presentation at the Annual Meeting, New York, December 5 to 9, 1921, of The American Society of Mechanical Engineers. The paper is here printed in abstract form. All papers are subject to revision.

formity to such an extent that it can be burned in the furnace with a 10 per cent improvement in economy. However, the labor saving due to automatic feeding is slight, and should not be confused with the labor saved by the use of coal-handling equipment and overhead bins, always a good investment for installations of more than one producer.

Automatic Agitation, if suited to the kind of coal used, will increase the B.t.u. from 10 to 20 per cent (depending largely upon the zeal and skill with which it was formerly hand-poked) and the uniformity thus obtained will cause a corresponding saving in utilizing the gas in the furnace. The combined effect of automatic

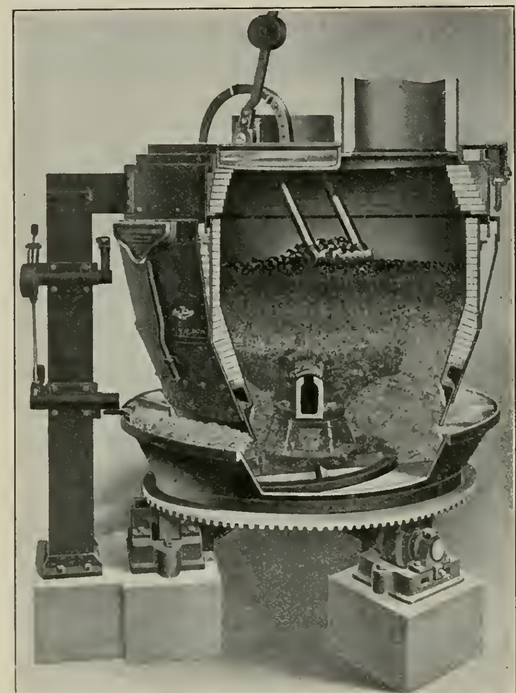

Fig. 3 Morgan Producer

feeding and automatic agitation usually makes possible a saving of 25 per cent of the fuel required for a given operation.

Automatic Ash Removal is of two kinds—intermittent and continuous discharge. The intermittent type removes the ashes once or twice in 24 hours. It is open to the objection that during the ash-removal period the fire is badly disorganized and a poor quality of gas is made for possibly half an hour. The continuous type of ash removal is entirely free from this objection. In Europe the continuous type is much in favor, although but few have been installed in this country.

The saving caused by mechanical ash removal depends largely upon the kind of device used. If the ashes are removed intermittently, and if no effective agitation accompanies the ash removal, the saving will be limited to the two or three hours' time required daily for the ash men to shovel the ashes out by hand. If, on the other hand, the ash removal is continuous and is accompanied by suitable agitation of the entire ash bed and lower portion of the fire bed, there will be a considerable saving in the labor required both for manipulating the fire and for cleaning clinkers off the walls. Moreover, the continuous type of ash removal, accompanied by ash agitation, will increase the capacity of the producer about 50 per cent and will save some fuel on account of the improvement in the quality and uniformity of the gas. Unfortunately the continuous type of ash remover, combining with effective agitation, is little known in this country, although it is the common type in use throughout Europe.

Types of Producers

Bearing in mind the foregoing three steps in making producer gas, let us now consider the types of producers in most common use in America, the Hughes, the R. D. Wood,[1] the Morgan and the Chapman. Each is an excellent machine.

To Mr. Hughes, then chief engineer of the Pencoyd Iron Works, is accorded the credit for having installed at that plant in 1897 the first successful mechanical producer in America. This machine is still in operation. As will be seen from Fig. 1, the chief feature consists in a vertical water-cooled finger hinged to the stationary top of the producer and made to oscillate between the center and the wall while the body of the producer and its contents revolve underneath. Thus, in time, the entire contents of the producer are stirred. The speed of this producer was originally one revolution in 20 min., but every few years it has been increased until now the walls make one revolution in 8 min., with considerable increase in capacity.

Since the installation of the first Hughes producer, an automatic ash-removing device has been added. It consists in a stationary bar arranged to sweep the ashes from a revolving grate. The bar

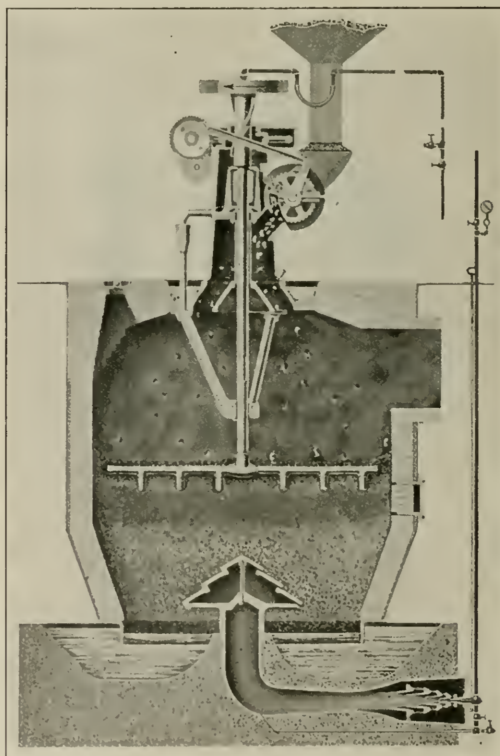

Fig. 4 Chapman Producer

is inserted once or twice every 24 hr. for a short period and then removed. No attempt is made to use the device for agitating the lower portion of the fire bed. Recently an automatic feed—in fact two automatic feeds—has been added, thus making the producer completely mechanical. The double feed gives unusually good coal distribution. This is the oldest producer on the market, and there are over 800 in operation—more than any other mechanical producer.

[1] The Wood type is manufactured by two different companies.

The R. D. Wood producer, Fig. 2, is somewhat like the Hughes, in that it uses the vertical-stirring-arm principle. There are two vertical arms, one near the center and the other near the wall. These stirring arms are bent as shown in the illustration, but instead of oscillating from center to side they revolve around their vertical axes. The walls of the producer revolve and thus the fire bed is carried past the stirring device. The coal is fed from a rotating drum located eccentrically. As the revolving fire bed comes under the feeding device fresh fuel is supplied to it. The speed of the producer is one revolution in 30 min. A steam-turbine blower is supplied in addition to the ordinary steam-jet blower. The turbine has an extra large capacity, operates quietly, and usually gives results that are more uniform than a steam-jet blower.

The ash is removed by a blade or plow attached to the lower edge of the revolving producer wall and extending down into the ash bed. The blade takes out ashes at a fixed rate, which is somewhat faster than they are made and therefore it cannot be operated quite continuously. Scoops are attached to the skirt of the revolving wall for carrying the ashes aronnd to a suitable point for final discharge. The capacity of this producer is unusually large, owing to the facts that there are two stirring arms in place of one, and the removal of the ash is nearly continuous. Moreover, the diameter of the Wood producer is 10 ft. 6 in., instead of the usual 10 ft. This producer is particularly popular among glass mannfacturers, and some remarkable records have been secured with it.

In a producer having vertical stirring fingers it is highly desirable to keep the top and bottom of the fire bed always at the same level so that the stirring fingers will always project the right distance into the fire bed for best results. If these fingers should reach too near the ashes, the air blast would break through into the recess or gap left in their wake and spoil the gas. A continuous, or at least semi-continuous, ash removal would thus seem to be necessary in order to keep approximately the same amount of ashes in the fire bed all the time and approximately the same amount of fire.

The Morgan prodncer, Fig. 3, like the Hughes, is 10 ft. in inside diameter and has about the same capacity. Also, like the Hughes, it is very popular in the steel trade. However, it differs radically in both the method of agitation and in the ash removal. Instead of vertical arms projecting deep into the fire bed, a horizontal arm which rides on the surface is used, it being claimed that surface agitation is quite sufficient and anything more is detrimental. The writer's experience would seem to prove that surface agitation is hardly adequate when caking coals are used. Nevertheless some very excellent results have been obtained. As will be seen from the illustration, the agitator is in the form of a swinging U-tube with the ends hinged to the stationary top of the producer. The walls and the ashpan of the producer revolve and carry the fire bed around with them. The speed has recently been increased to one revolution in twelve minutes.

The ash is removed by a spiral arm lying on the bottom of the ashpan. Ordinarily the arm revolves with the pan so that no ashes are removed. From one to three times every 24 hr. the outer end of the spiral arm is engaged and held fast, thus producing relative motion between the arm and the pan and causing the ashes to flow out rapidly. An ingenuous device provides for the automatic release of the ash arm when the producer has made a full revolution. The ashes obtained in this way are exceptionally free from carbon. After the ashes are taken out the fire bed is "broken down" by hand poking and drops from six inches to a foot.

In all gas producers that do not provide for continuous removal of the ash there is a definite *cycle of operation*, extending from one ash-removing period to the next. This is usually a 24-hr. cycle, but in some cases it is 12 or even 8 hr., and in the case of the Wood producer it is semi-continuous. At the beginning of the cycle (immediately after the ashes have been removed) the fire bed, though not changed in thickness, is located much lower down in the producer than at the end. This difference in height of the location of the fire bed in the producer from the beginning to the end of the cycle is usually about 2 ft. if the ashes are removed but once in 24 hr., but is correspondingly less when the ashes are removed more frequently. It is therefore apparent that if a producer is to be agitated uniformly it should be provided either with approximately continuous ash removal or with an agitator which automatically varies in height according to the varying height of the fire bed.

The Chapman producer, Figs. 4 and 5, is the only gas producer sold in parts. The agitator alone may be installed on any stationary producer, or the agitator in combination with the automatic feed may be installed on old or new stationary producers, or, again, a completely mechanical producer including automatic feed, agitator and ash remover may be obtained. The agitator, as will be seen from the illustrations, is in the form of a rake with water-cooled teeth. The rake revolves once in 7 min., and thus every portion of the fire is passed over every $3^1/_2$ min., which is more than twice as frequent as in any other producer. In most producers agitation depends upon the speed of the walls, which are rather cumbersome to operate rapidly.

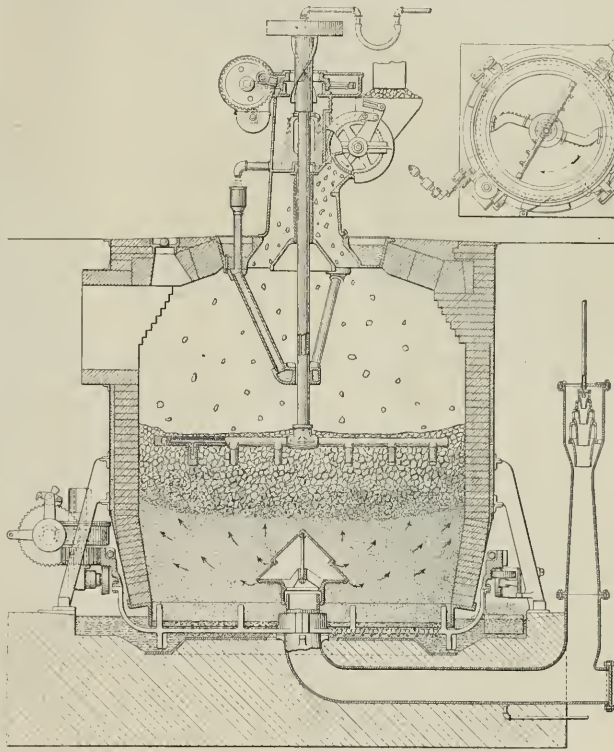

Fig. 5 Chapman Continuous Gas Producer

The agitator is driven by a patent driving head having two long spiral flanges upon which the agitator automatically "screws up" as the fire bed grows higher and "unscrews" when the height of the fire bed drops. These spiral flanges are in sliding contact with two revolving lugs which project inwardly from the hub of the driving wheel. As fresh coal is put on the fire it tends to bury the agitator beneath it. This makes the agitator turn harder through the fire bed, and immediately the torque is increased the driving head screws up to where the forces are again in balance.

If the agitator strikes a large clinker fast to the wall it screws up over it and drops down on the other side, thus avoiding any undue strain on the machinery. The action is a little like that of the Yankee screw driver.

The cross-arm of the agitator operates a few inches below the surface of the fire bed, and the fingers project down 8 in. farther. This makes the depth of the agitation about midway between the surface agitation of the Morgan and the deep agitation of the Hughes and Wood. As the fingers project forward the cross-arm immediately fills in the gaps in their wake. The out-stroking effect of the cross-arm tends to pack the fuel against the wall, which helps to prevent blowholes and clinkers.

The automatic feed drops the coal evenly over all parts of the fire bed simultaneously, and thus does not require a revolving fire bed. The object is to produce slightly better gas-making conditions than when the fuel is dropped only in one corner or sector of the producer at a time.

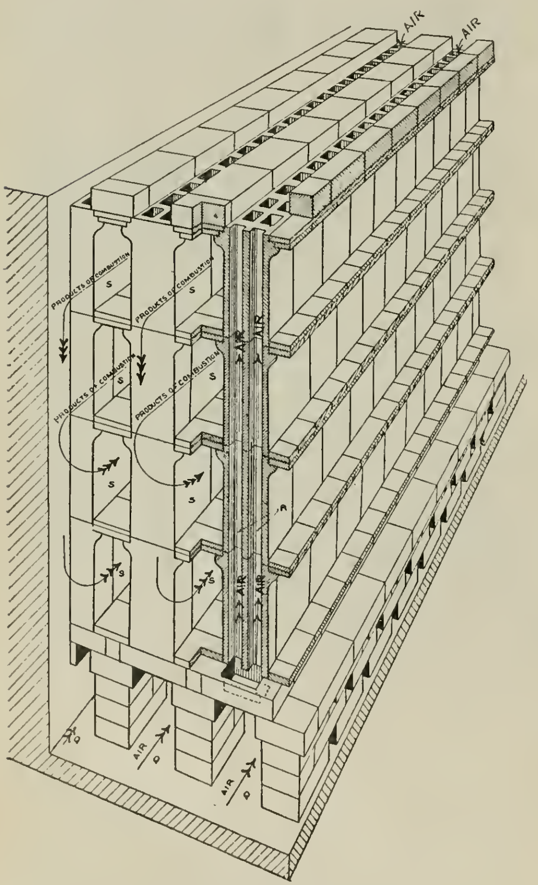

Fig. 6 Stein Recuperator

The ash-removing device operates continuously. It consists in a slowly revolving beam extending across the producer through the ashpan and driven by a gear ring which encircles the producer just above the pan, the speed being adjustable to synchronize with the rate the ashes are being made. The speed of the gear ring is adjustable from a revolution an hour to one in ten hours. After the ashes have been forced out by the beam into the outer portion of the ashpan they are picked up by scoops attached to the gear ring and carried to the point of discharge.

The Chapman producer makes use of the European idea of agitating the firebed from beneath. The ash beam is provided with fingers which project upward and impart motion both to the ashes through which they move and the fire bed resting on the ashes. This is to help in preventing blowholes and clinkers and to increase the capacity.

The size of this producer is 11 ft. inside diameter—the largest made—and the capacity is increased accordingly.

Savings With Mechanical Producers

With the usual more or less unskilled and indifferent handling, any of the four American mechanical producers can make a gas averaging 150 B.t.u. (low values) instead of the customary 125 B.t.u. obtained in hand-poked producers if operated with zeal. With skilled handling the best mechanical producers will average from 160 to 175 B.t.u., provided the coal is fair and the rate of gasification does not exceed 25 or 30 lb. per sq. ft. per hr., which is about twice the capacity of hand-operated producers.

A Duff producer, operating originally at 10 tons a day and making gas having 125 B.t.u., was fitted with a Chapman agitator and automatic feed, and at 36 tons a day gave an average of 163 B.t.u. Similarly, a Von Kerpley producer, the most popular mechanical type in Europe, gasifying 20 lb. per sq. ft. per hr., making about 135-B.t.u. gas, was equipped with Chapman agitator and automatic feed and changed to 34 lb. gasified per sq. ft. per hr. and 178 B.t.u. This was maintained without difficulty and without any hand poking.

The best modern producers properly operated will usually save about 25 per cent of the coal and an equal amount of labor. These savings should amount to the total cost of the installation in from one to four years.

The temperature in a gas producer is highest at the bottom of the fire, and the thicker the fire the cooler the top. The temperature at the bottom should be as high as the fuel will stand without running too much risk of melting the ash. The melting point of the ash in all the good Pittsburgh gas coals is well above 2500 deg. fahr., and the melting point of the ash in Illinois coals is about 300 deg. lower. The temperature at the top of the firebed should be as low as will permit the gas to be conducted to the place of use without forming objectionable tar deposits, and also as low as possible without making the top too sticky and difficult to blow through. Usually a "top temperature" of 1000 deg. fahr. is about right, but if the gas is to pass through a water-cooled reversing valve located some distance away 1200 deg. would be better. A "hot top" destroys some of the richest gases and thus wastes fuel. More fuel is wasted in a producer from running with a hot top, i.e., over 1300 deg., than from any other cause.

A considerable saving of coal can be brought about by using suitable accessories in the gas house. The most important of these is a pressure regulator, which, when the pressure in the gas main falls, blows the producer harder and makes more gas, and vice versa. A temperature recorder is also of great assistance. A few additional regulating and recording devices are needed if one is to obtain the highest efficiency in daily operation.

The Furnace Part of the Problem

But, *gasifying the fuel is only half the problem of conserving it.* The other half lies in its utilization in the furnace. The two halves of the problem are inseparable. They are both the field of the combustion engineer. Space is too limited to take up more than one kind of furnace—the kind that holds the most promise for fuel conservation and the kind that until the last decade has largely been a failure—the recuperative furnace.

A recuperative furnace is never "reversed" and, except in rare instances, only the air is preheated. It costs much less to build and to repair, is easier to operate and gives practically the same efficiency as the expensive and cumbersome regenerative furnace.

The field of application for the recuperative furnace is very broad and it can be used effectively in both large and small operations, for furnace temperatures as high as 2700 and as low as 1400 deg. About the only uses to which it is not suited to are for operations which periodically require a large overload such as the open-hearth process and large forgings over 32 in. in diameter, also for large glass melting tanks. For almost all other purposes the recuperative furnace can be used with great economy.

In many operations where the air is not now preheated it will be found that from 20 to 40 per cent of the fuel can be saved by using a good recuperator—one that preheats the air to within 500 deg. fahr. of the temperature of the furnace.

The Stein recuperator is shown in Fig. 6 and the Stein recuperative furnace in Fig. 7. The furnace is the one most favored in Europe, where, as might be expected, the necessity for fuel economy has caused engineers to give more attention to the problems of combustion than in this country. The recuperator of this furnace preheats the air to within less than 500 deg. fahr. of the temperature of the gases leaving the furnace and is as efficient after six years of operation as when first installed.

Another distinctive feature of this furnace is that the gas and air are mixed together a few feet before they enter the furuace but are not given room enough to burn until they reach the combustion chamber. A high heat is then obtained immediately.

The recuperative tile in this furnace is set to form horizontal passages for the spent gases, the joints being protected by a double seal. Each tile is provided with four small vertical passages for the air. These passages form straight chimneys about 6 ft. high with no

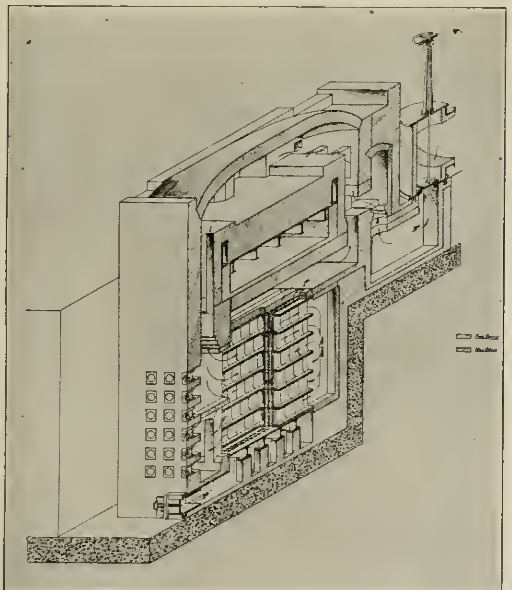

Fig. 7 Chapman-Stein Forge Furnace

offsets or turns to hinder the accelerating speed of the rising column of air. The energy of velocity of the air thus attained is transformed on entering the furnace into the energy of pressure. The furnace is thus automatically operated under a slight pressure without requiring the usual blower for the air. The saving of a blower and the power to operate it, however, is not so much of a gain as the fact that the air in the recuperator is not under pressure (from a blower) but under suction caused by the chimney effect of the vertical passages, and thus the suction of the air inside the tile balances the suction of the spent gases in the passages between the tile. There is therefore no leakage—in fact no cause for leakage—from the air passages to the gas passages, which has been the bane of the recuperative furnace heretofore.

To give one example, a furnace of this description installed in this country nine months ago is now performing a certain heating operation which formerly required 550 gal. of oil a day for 350 gal., a saving of 36 per cent. The saving in oil for the first year will more than pay for the cost of the furnace.

Large Fuel Savings Possible

It is not the purpose of this paper to dwell on pulverized coal or oil as fuel, but 20 to 40 per cent of these fuels might be saved if air for combustion were properly preheated from the waste gases by a suitable recuperator.

In view of the facts as outlined in this paper we trust that many will agree with us that from 3,000,000 to 4,000,000 tons of bituminous coal could be saved annually by better furnaces and furnace operation, and better producers and producer operation. May we therefore suggest that our Society in the future take suitable action in recognition of the situation herein set forth.

In closing the author wishes to acknowledge the kind coöperation of the Morgan, Wood, and Hughes companies who have supplied the illustrations of their producers and also some of the information contained herein.

Appendix 1

As there are more Duff producers in use in the United States than any other type of hand-poked producer, the following test made by the engineers at one of the largest steel works will be of special inter.st.

TABLE 1 TEST OF DUFF-BRADLEY PRODUCER WITH NEW BLOWERS AND CHAPMAN AUTOMATIC FEED FLOATING AGITATOR.[1]

Analysis of Seven-Hour Continuous Sample of Gas

Rate of gasification per 24 hr. = 37.36 tons.
Rate of gasification per hr. per sq. ft. = 36 lb.

CO_2 per cent	C_nH_{2n} per cent	O_2 per cent	CO per cent	CH_4 per cent	H_2 per cent	N_2 per cent	B.t.u.	Steam lb.
4	1.4	0.2	26.8	3.0	10.4	54.2	163	52

Calorific power of gas per min	552,750 B.t.u.
Sensible heat of gas per min	94,100 B.t.u.
Total useful heat of gas per min	646,850 B.t.u.
Average coal fed per hr., lb. by weight	3114
Average coal fed per hr., lb. calculated from above analysis	3081
Difference, lb	33

External Heat Balance

Dr.	B.t.u.	Per cent	Cr.	B.t.u.	Per cent
B.t.u. per lb. coal	13,039.0	97.5	Calculated power of gas	10,660.0	79.7
B.t.u. steam and air	336.5	2.5	Sensible heat of gas	1,803.0	13.5
			Loss unburnt coal	146.5	1.1
			Other loss (radiation, etc.)	716.0	5.7
	13,375.5	100		13,375.5	100

Total losses, 6.8 per cent.
Efficiency of producer, 93.2 per cent.
Standard gas temperature of 62 deg. fahr. used.
No band poking was done during test and no clinkers were made.
In calculating B.t.u., U. S. Steel Corpn. lower values are used.
West Virginia coal used carrying 37 per cent volatiles.

[1] Former capacity of this producer was 10 tons in 24 hr. and the gas averaged 125 B.t.u. Producer was rebuilt to 10 ft. 6 in. diameter.

Appendix 2

As there are more Von Kerpley producers in Europe than any other mechanical type, we give the following test. The Kerpley producer, like the other European producers, has continuous ash removal and continuous agitation of the ash bed and lower part of the fire bed, and there is no agitation of the upper part of the fire bed and no automatic feed. Before installing the Chapman automatic feed and floating agitator the capacity was 12 cwt. per hour and in spite of an enormous amount of hand poking the producer was usually full of clinkers. After the new equipment was added the capacity was increased considerably over 50 per cent, no hand poking was required and no clinkers were made. The works engineer estimated that the saving in labor alone was sufficient to pay for the equipment in nine months. The B.t.u. in the gas was increased about 30 per cent.

TABLE 2 TEST OF VON KERPLEY PRODUCER, WITH CHAPMAN AGITATOR AND AUTOMATIC FEED

Test on 9 ft. 7 in. inside diameter Von Kerpley gas producer fitted with a Chapman agitator with automatic feed.
Duration of test, 49½ hr.
Average analysis of gas samples taken hourly:

CO_2	O_2	CO	C_2H_4	H_2	CH_4	N_2
4.74	0.30	24.6	0.30	12.80	5.26	52.00

Total combustibles, 42.90 per cent.
Average coal fed per hour, 2408 lb.
Calorific value of gas, 178 B.t.u. per cu. ft.
Net English heat values used: CO—345, H_2—290, CH_4—975, C_2H_4—1590.

Heat Balance

Dr.	B.t.u.	Per cent	Cr.	B.t.u.	Per cent
B.t.u. per lb. coal	13,906.0	97.2	Calculated power of gas	11,498.9	80.34
Sensible heat of coal	13.2	.09	Sensible heat power	1,925.0	13.50
Sensible heat of steam	328.8	2.3	Loss in unburnt coal	46.3	.32

Total losses, 6.16 per cent.
Efficiency of producer, 93.84 per cent.
Producer equipped with Chapman 5-stage blower with 7/16 in. nozzle.
Coal used: Florence beans 17.62 per cent, Florence nuts 30.65 per cent, Stafford cobbles 20.73 per cent, Florence cobbles 31.00 per cent.
Coal gasified per sq. ft. per hr. 34.01 lb.
Steam used, 0.278 lb. per lb. of coal.
Gas per lb. of coal, 64.6 cu ft.

Boiler-Plant Efficiency

By VICTOR J. AZBE,[1] ST. LOUIS, MO.

The usual wastes in boiler plants are brought out strikingly by means of tables and curves of boiler performance compiled from a large number of observations.

The object of this paper is to show to what extent these wastes are preventable or can be made to balance each other, and to recommend a standard for boiler operation toward which designers and operators of boilers may aim.

The author considers that there still remains an immense field for experimental research to obtain the necessary data for boiler construction. The requirements of the ideal boiler installation of today are summarized.

The degree of waste in boiler plants is not generally realized and there is a tendency to judge conditions by a few of the better plants where improvements have been made and whose results are considered as representative of the average-run boiler plants.

Tables 1 and 2 show two boiler tests made under ordinary operating conditions, one on a hand- and one on a stoker-fired boiler. During these tests care was taken that actual operating methods were pursued. The results are very bad but representative of most smaller and some of the larger installations.

Table 3 gives the results of three boiler tests, all made on the same boiler some time apart. The boiler was of the B. & W. type, but poorly set, with a limited combustion chamber of only 0.87 cu. ft. per rated boiler hp. The stoker in use was of the old Jones type.

During Test A the aim was to maintain the same operating conditions as existed before any improvements were made; the result was an efficiency of 56 per cent and boiler rating of 102 per cent. After this first test improvements were begun, without, however, altering the stoker or increasing the combustion space.

After about six months, results were obtained as represented by Test B in Table 2; the efficiency was increased to 68.5 per cent and capacity to 140 per cent of rating. The results were not as yet considered satisfactory and efforts for further improvement were made. In all about 30 boiler tests were run under different conditions and with different fuel and one of the last tests is represented by Test C in Table 3. This last test is very remarkable in several respects, but is correct. In fact, the results are checked by other tests giving equal or even slightly better results.

The remarkable features of the results of this test are as follows:

1. High boiler efficiency with a relatively inefficient installation and relatively poor coal
2. Complete combustion with high volatile coal and a combustion space of only 0.47 cu. ft. per developed boiler hp. or 0.11 cu. ft. per lb. of coal including the space occupied by the coal
3. A draft drop through a 16-section, 9-tube (each 16 ft. long) B. & W. boiler of only 0.1 in. at 85 per cent overload
4. A flue-gas temperature of 532 deg. fahr. at 85 per cent overload in spite of the limited combustion space and flame extension to almost the end of the first pass
5. An improvement of 39.5 per cent in economy over that of Test A
6. An improvement of 81.4 per cent in capacity over that of Test A, in spite of the fact that during the first test maximum boiler rating was aimed at. Other examples could be enumerated of great improvements being made.

Standard of Economy

The writer considers 90 per cent efficiency as the standard of economy attainable under favorable conditions, this 90 per cent representing boiler and economizer without taking auxiliary power into consideration, however. The requirements for this efficiency are rather severe and with 12,000 B.t.u. bituminous coal, 15 per cent excess air would have to be used, flue-gas temperature would hav to be no more than 250 deg. fahr., combustion complete and n carbon in the ash. These requirements are listed in Table 4

TABLE 1 TEST ON HAND-FIRED BOILER REPRESENTING VER UNECONOMICAL CONDITIONS

Date of test	Dec. 2, 1920
Type of boiler	B & W
Grate	Shaking
Kind of coal	Illinois screening
Steam pressure, gage, lb	135.6
Temperature of feedwater, deg. fahr	205.0
Temperature of flue gas, deg. fahr	568.4

Total loss	10.00
Boiler efficiency	90.00

[1] Consulting Engineer. Assoc-Mem. Am.Soc.M.E.

For presentation at the Annual Meeting, New York, December 5 to 9, 1921, of The American Society of Mechanical Engineers. The paper is here printed in abstract form and advance copies of the complete paper may be obtained gratis upon application. All papers are subject to revision.

This ideal or 90 per cent boiler and furnace efficiency has been attained only once, and then by Henry Kreisinger and John Blizard at the Lakeside Station of the Milwaukee Electric Railway & Light Co.

Fuels

With a suitable installation, almost as high an efficiency will be obtained with low- as with high-grade fuels. The only real obstacle to this is the tendency toward a greater ashpit loss with lower-grade fuels.

As a rule low-grade fuel should be burned close to the mines and igher-grade fuel transported. Freight to distant points should not be compared on a tonnage but on a heat-value basis. The cost of fuel also should be based on heat value rather than on the weight.

Combustion

There are several reasons why properly proportioned furnaces with ample combustion space are necessary, the most important being the prevention of escape of unburned gas and formation of

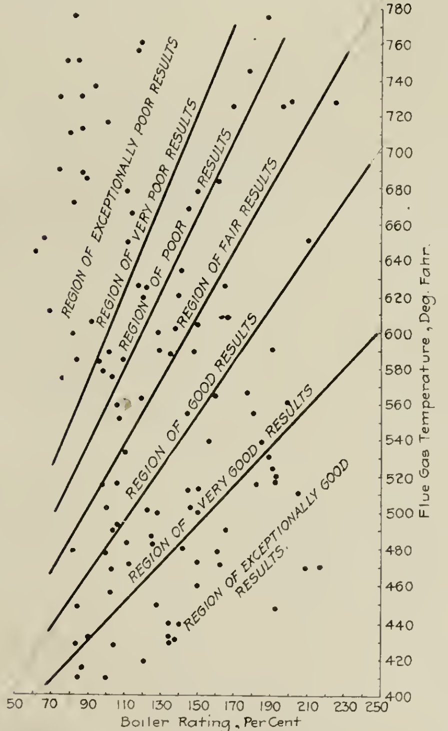

Fig. 1 Flue-Gas Temperatures Representative of Good and Bad Results

soot, the possibility of operating with the least amount of excess air without incomplete combustion, and the prevention of flame entrance among the boiler flues. This last is necessary to obtain low flue-gas temperatures and will be considered under that head.

Furnace volumes vary from 1 cu. ft. per lb. of coal burned per hr. down to less than 0.1 cu. ft. in some cases. The lower amounts, of course, do not represent the entire combustion space because combustion under such conditions extends among the tubes, at times for a considerable distance, but this is not what is to be desired. The larger amounts are used with powdered fuel and are necessary because the solid particles burning are relatively large and require a larger combustion chamber for their gasification and combustion than is the case when gasification, and to a certain extent mixing with air, takes place on a grate.

The aim is to have the gas completely burned and no flame entering the first tube pass. To accomplish this, more than mere furnace volume is necessary. There are such things as effective and ineffective combustion space.

Excess Air

The largest preventable loss in boiler plants is that caused by excess air. Determination of this loss by the measure of the CO_2 and flue-gas temperature has achieved considerable popularity.

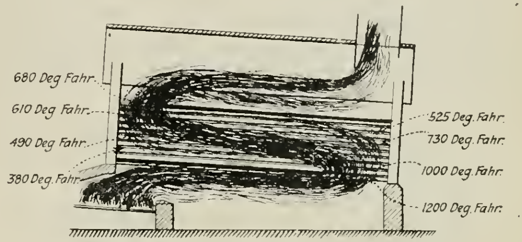

Fig. 2 Unequal Gas-Flow Distribution Through a Boiler

Where such popularity has been attained, the trouble is, however, that quite generally there is satisfaction if the fuel is burned with 100 per cent excess air, and even in well-operated plants no better results are obtained on the average. This is because of the tendency of many an engineer to assume statements as correct without sufficient consideration. With the large combustion chambers coming in vogue nowadays the old assumption that 10 or 12 per cent CO_2 is all that pays becomes obsolete. If we design our furnaces so that flame terminates before gas enters the tubes or soon thereafter and with the boiler heating surface so exposed that the maximum amount of heat is radiated to it, then the standard of good performance is the burning of the fuel with 15 or at the very most 25 per cent of excess air, and the CO_2 maintained should be around 16 per cent.

The point at which excess air enters in very important and should be given greater prominence when boiler-test data are recorded. At present during a test we tend to be primarily concerned with what occurs on the ends; that is, in the furnace and uptake, and few, if any, observations are taken and records made of what occurs between these points. Such items as point of flame termination, relative amount of oxygen, carbon dioxide percentage (which is a true measure of excess air), and temperature drop at various points through the settings, should be carefully recorded and interpreted; then it will be possible to really compare the performance of one boiler with another, which can hardly be properly accomplished with the data now commonly obtained.

A somewhat overlooked but also very important factor affecting boiler plant economy is "constancy." The percentage of CO_2 may fluctuate during the day from high to low, but if for the whole day a 10 per cent average is taken, it will be found that for a number of reasons the efficiency will not be nearly so good as when 10 per cent of CO_2 is constantly maintained. Therefore the average CO_2 is an improper measure of the loss, but at the same time is a good indicator of improper conditions.

Heat Transfer and Flue-Gas Temperature

The temperature of the escaping products of combustion determines fuel loss to a great extent, but what is low and what is high flue-gas temperature? The lack of a suitable measure and standard has in the past prevented proper comparison of results and has also caused a certain lack of incentive for improvement. The writer, in his effort to evolve a measure, has drawn Fig. 1 based on 150 different boiler tests. Each dot represents the average flue-gas temperature at the average rating developed in each test. The space is divided into sections varying from exceptionally good to exceptionally bad results, with the slope of the line following as closely as possible the increase of flue-gas temperature with the increase of boiler output of a number of boiler-test series.

To absorb the heat, it is necessary to bring the gas in contact with the heating surface. This some boilers do imperfectly. If the surface is clean everything depends upon gas velocity and distribution. Fig. 2 shows what happens under certain conditions. In the dead spaces temperatures as low as 380 deg. fahr. were recorded when the flue-gas temperature was 680 deg. fahr. The gas has the tendency to take the shortest cut, a great deal like a stream of water; in fact, much might be learned from the study of water stream flow which could be applied very profitably to boiler-pass design.

Fig. 3 was drawn as an effort to show how boiler-heat transfer varies according to different influencing factors.. This chart is interesting from many angles and while not exactly correct for all conditions, it is sufficiently so to permit its use The chart is

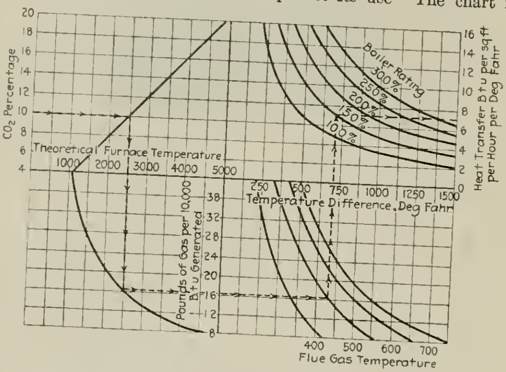

Fig. 3 Boiler Heat-Transfer Variation Under Different Conditions

Based on 365 deg. fahr. steam temperature.

based on the theory that from the actual heat-transfer standpoint we are not concerned with what the furnace temperature is, but only with the maximum theoretical temperature that would have existed had there been no absorption of heat in the furnace. If the boiler absorbed no heat from the furnace, the theoretical temperature corresponding to CO_2 would be obtained very nearly. According to this theory, if CO_2, flue-gas temperature, and rating at which boiler is operated are known, heat transfer can be determined with the aid of the chart.

Fig. 4 demonstrates that with 140 lb. boiler pressure, from 14 to 25 per cent of the total heat used to generate steam is required just to heat the feedwater 350 deg. fahr. It also shows how the necessary boiler and economizer surface varies with different temperatures of feedwater and that the total boiler and economizer surface is less than the necesary surface of the boiler only without economizer. For maximum economy, counter-current heat-flow effect must be employed in boiler plants.

Economizers pay under almost any conditions if they are installed correctly, especially if we take into consideration that they replace more than their own amount of boiler surface. It should be general practice to install smaller boilers which may be forced to greater overloads and the consequently high flue-gas temperatures reduced in economizers. Water should always enter boilers at above 325 deg. fahr. In fact, it is the approach of feedwater temperature to steam temperature in the boiler that is a measure of fuel loss resulting from not employing at all or not to full enough extent the principle of counter-current heat flow. Fig. 5 applies when there is sufficient heat in the flue gas to heat the water to the temperature of the steam, giving the fuel loss for whatever temperature of water enters the boiler. With this chart, it is possible to tell not only what good a certain economizer installation accomplishes but also what good it does not accomplish.

Boiler Capacity

When boiler capacity is increased by the burning of more fuel, the following either does or may occur:

1 Temperature in combustion chamber increases
2 Temperature of gas throughout boiler setting increases
3 Temperature difference between water in boiler and gas surrounding tubes and drums increases
4 Gas velocity increases
5 Heat absorption by radiation increases owing to higher furnace temperature
6 Heat absorption by convection increases owing to higher gas velocity and higher temperature difference
7 Flue-gas temperature increases
8 Dead spaces become more active
9 Incomplete combustion increases

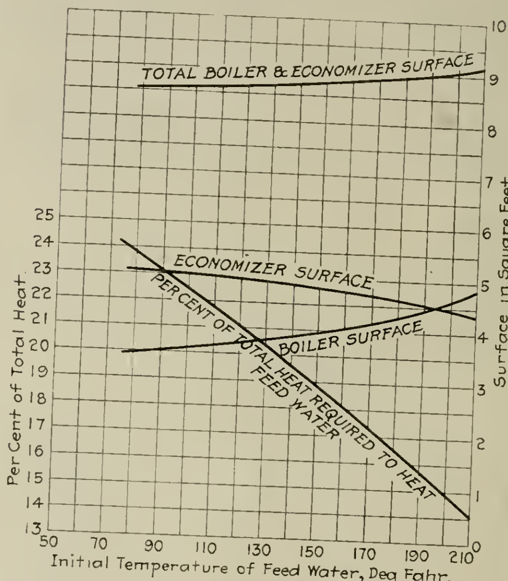

Fig. 4 Heat Required to Raise Feedwater to Temperature of 350 Deg. Fahr.

Based on economizer heat transfer of 3 B.t.u. per sq. ft. per hr. per deg. fahr.

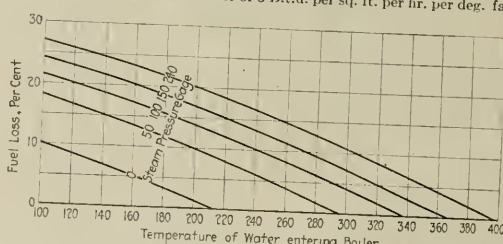

Fig. 5 Fuel Loss When Water Enters Boiler Below Steam Temperature

This figure applies only when water could be preheated by waste heat.

10 Fuel loss resulting from air in leakage and radiation expressed as a percentage of total decreases
11 Excess air decreases
12 Fireman's attention usually increases
13 Return received from investment increases.

There are several factors in this list that counteract each other, some increasing and others reducing efficiency, but as a balance, within limitations, increased boiler capacity is more economical, especially when the installation is correctly made.

It is the writer's experience that the very large majority of plants possess and operate too many boilers, at times twice as many as necessary. The cry is, "Give us plenty of boilers," and the result is waste in investment and waste in operation.

Since high boiler efficiency at low ratings is more difficult to obtain than at high ratings, it follows that owing to this and also for

(Continued on page 726)

Fuel Saving in Relation to Capital Necessary

Investigation Shows Economy Resulting From Use of Efficiency Equipment—Concrete Illustrations Given in Support of the Theory Discussed

By JOSEPH HARRINGTON,[1] CHICAGO, ILL.

SOMETHING definite and reliable in the way of information for the enlightenment and guidance of the prospective investor in efficiency equipment seems to be needed, and the object of this paper is to provide evidence to support the rather general understanding that it pays to economize. The author's original opinion was that there would be no difficulty in obtaining an abundance of first-hand information from engineers and owners who have recently installed efficiency equipment. These men invariably express satisfaction with the outcome of their endeavors, and it was thought that a compilation of such evidence would be the best possible manner of presenting this subject to the public.

In furtherance of this idea, numerous letters were written to consulting engineers, chief engineers of power plants, and owners, stating the desire of the author to secure such data. In all cases, with about three exceptions, the replies were similar, and to the effect that, while they had done this class of work, they had no records or data on which to base any figures, and they were therefore unable to provide the information requested. This in itself seems to be a fitting subject for serious thought.

Engineers in general are supposed to work along lines of precision and not guesswork, and it seems rather like an unfavorable commentary on the profession, as a whole, to state that less than five per cent of those corresponded with were able to furnish any data at all. It seems necessary, therefore, to draw upon the experience of the few having such data and let these specific instances form the starting point for what is hoped will develop into a strong body of testimony in favor of efficient methods.

Let me first present a theoretical discussion which forms, in all cases, the nucleus of the whole matter. Consider a unit of 500 hp. to be operated at 200 per cent of rating over a 10-hr. manufacturing period with coal used for starting and banking, which brings up the total coal to the equivalent of 12 hr. at double rating. This then requires 12,000 boiler hp-hr. per day, which, at 4 lb. per hp-hr., amounts to 48,000 lb., or 24 tons of coal. Now, assume that the more efficient equipment will either utilize an equal tonnage of a grade of coal costing one dollar less per ton, or by an increase in efficiency reduce the amount of coal actually used by an amount which is the virtual equivalent of the one-dollar differential. We start, then, with either a direct decrease in coal cost or an efficiency producing a differential or saving of one dollar per ton. Twenty-four tons at one dollar would provide a net saving of $24 per day.

Now, the investment necessary to save this amount, we will say, is made up as follows:

One mechanical stoker	$5000
Fans and installation cost in excess of equivalent hand-fired setting	2000
Total	$7000

This amount of $7000 divided by 24, gives 292 days as the time required for completely recovering the initial investment. This is approximately the number of working days in one year, so that in this case, it could be stated that the investment provided a return of 100 per cent per annum. Should there be a greater or less differential in the price of coal or in the efficiency, this figure must be modified accordingly, or if there is a greater cost initially, the returns would be correspondingly diminished; but assuming that this is substantially correct, the dividends are of such magnitude as to overshadow any other form of investment other than finding the money or striking oil. It can be reduced to one-half or one-third of this figure, and still loom up as a phenomenal return for any concern, however prosperous. It is more than improbable that any such return can be secured by investing the same amount of money in equipment directly providing the output of the institution in question.

To support this by specific evidence, the author presents a few concrete illustrations. The power plant of the Waterloo, Cedar Falls and Northern Railway Company was overhauled in the fall of 1913, and the author followed this installation through for some two years thereafter, the results being published in the August

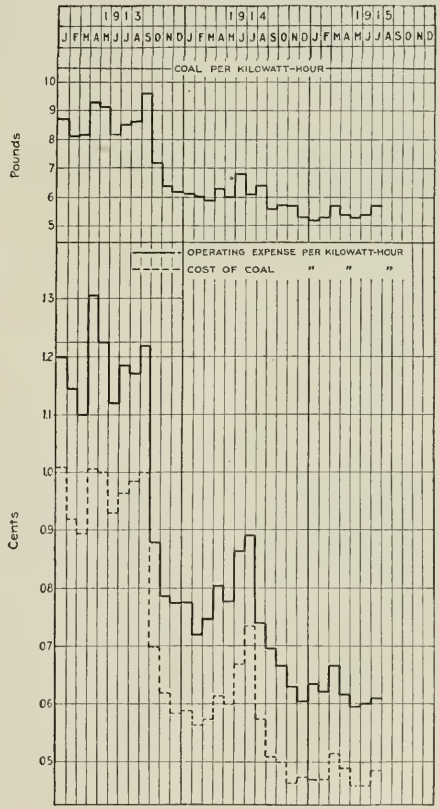

Fig. 1 Effect of Campaign to Cut Coal Cost

22, 1916, issue of *Power*. Two of the resulting curves are shown in Fig. 1. In this case there were four 500-hp. boilers installed, replacing older water-tube boilers which were also fired with the same make of stoker. With the same stoker, the same fuel, and similar boilers, the savings may very definitely be attributed to the greater efficiency secured by the then more modern setting. Not only was the furnace better proportioned and much more ample, but efficiency equipment was installed, such as gas-analysis recorders, draft gages, recording thermometers, feedwater heaters, and coal-weighing equipment. A simple system was developed for watching the indications of these instruments and drawing therefrom the logical deductions. In this particular instance, the new equipment actually paid for itself in a little over a year's time. It will be

[1] Vice-President, James A. Brady Foundry Co. Mem. Am.Soc.M.E.

observed that the coal cost per kw-hr. was just about cut in two.

During the summer of 1919 the Armour Institute of Technology made a change in their mechanical stokers from the old-style chain grate to the new traveling grate, boiler and other conditions remaining exactly the same.. The modern stoker had a better grate ratio (70 sq. ft. grate surface as against 90 sq. ft.) and was designed to be more efficient at the lower ratings which occurred during the major portion of the year. Only for about two months in the year was the boiler worked up to anywhere near its capacity. Natural draft was used throughout this period—chimney 175 ft. high. The average pressure was 100 lb. gage and the average feedwater 198 deg. fahr. The remarkable result of this change is best shown in the curves in Fig. 2, furnished by Professor Gebhardt, and in the accompanying data in Table 1. Owing to the fact that no change was made in this case other than the stokers, we can safely attribute the improvement to the improvement in the stoker.

Figuring on the basis of Carterville, Ill., No. 3 washed nut coal at $5.67 per ton delivered to the boiler-room floor, an annual gross saving of $1553.58 was realized on the total saving of 274 tons of coal. The average cost of repairs to date is $50. The approximate price of the new stoker was $3500 and the installation

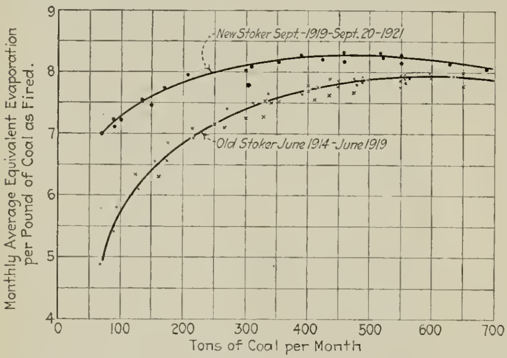

Fig. 2 Average Monthly Evaporation, 350-hp. Stirling Boiler, Armour Institute of Technology, Chicago

cost $1000, making a total of $4500. The return on the investment is therefore 33.3 per cent.

A third instance of a quite different nature is exemplified by the work of Neiler, Rich & Co. at the University of Chicago during the past season. The boiler room here consists of a number of 72-in. by 18-ft. horizontal return tubular boilers, stoker-fired, and using the usual run of bituminous coal that comes into the Chicago market. Considerable difficulty was experienced in carrying the 1919–1920 load on twenty boilers. Neiler, Rich & Co. undertook to keep this plant in operating condition until a new plant could be completed, so that what was done was merely for the purpose of keeping things going until that time, and not with the idea of a permanent improvement. No attempt was made to change any of the equipment, but it was found that the draft loss due to circuitous gas passages was very great, providing insufficient furnace draft. The combustion chamber was entirely too small, so that attention was given to improving these conditions.

By a change in the brickwork surrounding the boiler, both of these improvements were accomplished. Examining the boilers, it was found that there was insuffcient circulating space between the tubes; this was corrected by removing one of the center rows and several tubes at the sides, which too closely approached the shell. These changes provided circulating space for the downward and upward flow of the water.

Apart from patching up the brickwork, covering pipe lines, etc., nothing else was done; but it was found that these changes enabled the engineer to carry a somewhat increased load on fourteen boilers. The same coal was used, and the same chimney and breeching connections were retained, so that in this instance the economies are properly credited to improved boiler circulation, furnace draft, and combustion space. The coal saving is not proportional to the number of boilers used, because the better circulation in the boiler enabled higher capacities to be carried. Very accurate figures are not available in this instance, but it is beyond controversy that the cost of the improvements made will be covered by the fuel saving, within the period of two heating seasons.

BOILER-PLANT EFFICIENCY

(*Continued from page 724*)

investment reasons, boilers should be installed designed for high overloads and high and constant efficiency over a considerable capacity range. Especially in plants where load varies a great deal the boilers should be able to take the peaks; even if these peak loads are somewhat uneconomical they are to be preferred to boilers loafing the greater part of the time. As a rule good boilers, well installed, should be operated at between 150 and 200 per cent of rating, and when a peak is of short duration 300 per cent of rating is permissible. Ratings below 150 per cent should not be permitted except under unavoidable circumstances.

Features of an Ideal Boiler Installation

It may appear to some that the boiler with its appurtenances has been developed to what might be called the limiting point; this, however, is not so. There remains an immense field for experimental research to obtain the necessary data for boiler construction.

The ideal boiler installation of today should embody the following features:

1 A construction permitting counterflow where flue gas will heat the feedwater for the boiler which will enter the boiler at as nearly the steam temperature as load fluctuations will permit
2 A combustion chamber sufficiently large and effective throughout to prevent the entrance of any flame among the tubes, thus assuring complete combustion, absence of soot, and proper cooling of the gas
3 Boiler passes which will be effective throughout without dead spaces where there is no gas flow or only little, and in which the draft drop will be the minimum corresponding to gas velocity. The gas velocity will be the highest permissible by the cost of producing this velocity
4 Fuel resistance will be overcome by forced draft
5 The relative location of fire bed and boiler-heating surface is to be such that the maximum possible amount of radiant heat will be transmitted to the boiler surface consistent with complete combustion
6 Tight boiler walls properly insulated, probably an air-jacketed furnace, the air from which will be injected over the fire bed at high velocity to aid mixing effect or passed through the grate in the ordinary way
7 A stoker permitting combustion with no more than 15 to 25 per cent excess air, no more than 1.2 per cent unburned carbon in ashpit, no deposit of slag on the tubes and these conditions maintained at low and also at reasonably high ratings
8 Scale deposit in the boilers prevented by specially constructed self-cleaning boiler, external chemical treatment of feedwater, use of distilled makeup water, filtering of the water in the boiler by recirculation or by a combination of these methods.

Control of Centrifugal Casting by Calculation

By ROBERT F. WOOD, BAYONNE, N. J.[1]

In the application of various methods of centrifugal casting there arises frequently the question of the influence of speed of rotation upon the shape or characteristics of the casting. This is particularly true if the axis of rotation is not in a horizontal plane, in which case the effect of any change in speed of rotation or in inclination of the axis is immediately felt, since every such change is accompanied by a corresponding modification in the paraboloidal shape of the bore of the casting. For certain classes of work advantage is taken of this fact to produce centrifugal castings of more or less tapering shape, instead of cylindrical as ordinarily made, an instance in point being the production of cast tubes for submarine periscopes.

This paper analyzes the controlling factors, with a view first of setting down the definite mathematical relations between them, and secondly so expressing these relations as to make them useful both in the design of machines for casting and in the operation of such machines.

As a basis for this analysis there are selected several processes which have long been on record in the U. S. Patent Office, and an examination is made of the forces brought into effect when these processes are carried out. Equations and formulas are deduced which cover the general case and which can accordingly be used for the solution of any particular case; these are so arranged as to fit them for practical everyday use, and illustrations of their application are given.

CENTRIFUGAL casting, as here dealt with, concerns concentric methods or those wherein the axis of rotation lies within the casting, in a central position. As the casting operation may be carried out in a horizontal, a vertical, or an inclined position, methods of casting fall naturally into three corresponding divisions.

The simplest, oldest and commonest method of making centrifugal castings, and the one which produces by far the greatest tonnage, is with the axis of rotation lying in a horizontal plane. The fluid material, such as molten metal, is introduced into a horizontally mounted rotating mold, over the interior surface of which the material becomes spread out by the action of centrifugal force. When solidification has taken place there is obtained a casting whose outer conformation is a reproduction of the internal shape of the mold, and whose inner surface is cylindrical and symmetrical about the axis of rotation. This process has been experimented with for a hundred years or more, has been the subject of numerous patents for nearly as long, and has long been in commercial use in this and in other countries.

Vertical casting also has been practiced for a long time, but in its application has not found nearly so broad a field as has the horizontal method. Here again the method consists essentially of introducing molten metal or other fluid material into a rotating, but in this case vertically mounted, mold. Instead of forming a cylindrical inner surface, as in horizontal work, the metal here takes a bowl-shaped form; the shape of this curve is that of a paraboloid of revolution, and the higher the speed of rotation, the more nearly parallel will the sides of the paraboloid become. If the speed is kept relatively low the resulting casting will be only moderately hollowed out, or dish-shaped, and with intermediate speeds intermediate results will be obtained.

If the axis of rotation be inclined, a casting with a more or less bowl-shaped interior will result, and here too, by properly adjusting the speed, the bore of the casting may be made to approximate either the near-cylindrical or the bowl or dish shape. Mathematically considered, the inclined axis opens to us the general case, a concentric centrifugal casting made in any position; the horizontal and vertical positions are special cases at the two limiting extremes of the general proposition.

Castings with Paraboloidal Bores

The production of castings with paraboloidal bores by use of inclined or vertical methods is covered in a number of patents extending over the past fifty years. However, there is nothing to indicate that control of these methods was developed very far, and it is probable that their application was so limited that until lately there was no great need for refinement of control. We shall here refer to a few of the more important of these patents, and analyze the principles involved.

British patent 3819 by Taylor and Wailes in 1878 states that the inner surface of the casting forms "in fact a ring-shaped section of the paraboloid of revolution which is the form taken by the free surface of a mass of heavy liquid in rapid rotation round a vertical [or inclined] axis;" British patent 21,213 by Huth in 1895 states that the metal "is thrown to the periphery and is raised in such a manner as to form a parabolic curve to correspond with the velocity of rotation....The parabole....depends upon the radius of the wheel and the velocity of rotation;" and patent 98,673 by Davies in 1870 mentions the "hollow" or "basin" that forms in the center. The Huth and Davies patents are both for vertical machines; there is nothing to indicate whether or not work had been done with an inclined axis, but Taylor and Wailes are very clear on this point. Huth knew that a paraboloid was formed when casting vertically, and Taylor and Wailes were clearly aware that when made in any position other than horizontal the casting would have a paraboloidal

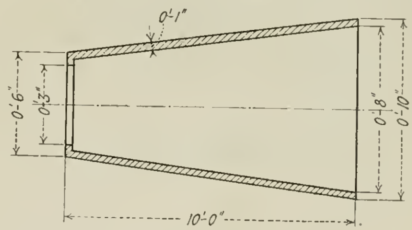

Fig. 1 Dimensions of Desired Casting

or basin-shaped bore. Davies proposed to cast cannon by his method, and Huth showed how, when casting shells, his plan was adaptable to making the bore of the casting somewhat conform by its paraboloidal shape to the pointed shape of the shell.

The inclined or the vertical method is indicated wherever the requirements of the shape of the bore can be approximated by a paraboloid, as for instance in the production of a casting whose finished bore is to be the frustum of a cone. The specific purpose for which this control was devised and used was the production of hollow tapering brass castings about 6 in. in diameter and upward of 20 ft. long for submarine-periscope tubes. However, as the solution is here worked out for the general case, it may be used to determine conditions for making concentric centrifugal castings of any size and in any position. Owing to the simplicity in principle of horizontal casting, it finds but little application there; inclined casting, however, is not so self-evident in principle, and really requires this exact means of control which is especially useful in connection with large work where cut-and-try methods are ruinous and where dependable data must be at hand before adequate specifications can be drawn for equipment, or intelligent plans made for its use.

It can be shown that the bore of a casting made with axis inclined is paraboloidal, and that the equation of the parabola has the form $x = ay^2$, with the axis of X coinciding with the axis of the casting and with the vertex at the origin. The coefficient a has the value $a = 0.61463\ (R^2/\sin\ \alpha)$, where R is the revolutions per second and α is the angle of inclination of the axis. Another value for the coefficient a is found to be $a = L/(y_2^2 - y_1^2)$, where y_2 and y_1 are any two radii (in feet) of the bore, and L the axial distance (in feet) between them.

Production of a Given Casting

Suppose now it is desired to produce a rough casting which will allow of machining to the shape and dimensions shown in cross-

[1] Metallurgist, Monel Metal Products Corporation.

For presentation at the Annual Meeting, New York, December 5 to 10, 1921, of The American Society of Mechanical Engineers. The paper is here printed in abstract form and advance copies of the complete paper may be obtained gratis upon application. All papers are subject to revision.

section in Fig. 1. Allowing finish on the various diameters and extra length for cropping, the rough casting to be obtained, with its dimensions, may be taken as shown in cross-section in Fig. 2, which also illustrates where the parabola will be located with respect to the casting.

Taking the radius of the large end of the rough casting as y_2 and the radius of the small end as y_1, the equation of the parabola which will generate the required bore is found to be $x = 121\ y^2$.

At this point it is well to determine the speed range within which the parabola $x = 121\ y^2$ may be produced. From the equivalent expressions for the coefficient a it is seen that for every assigned value of inclination α there will be a corresponding value for R, the speed of rotation. In the example before us the highest speed that may be used is found by assigning the values $a = 121$ and $\alpha = 90$ deg., which makes $R = 14$ revolutions per second or 840 r.p.m., for the mold vertically placed.

For a very elongated parabola, owing to the high value of the coefficient a the speed corresponding to vertical or steeply inclined positions may come out so high as to show at once that only moderate values of α should be selected if it is desired to avoid excessive speeds of rotation.

The lower limit of speed may be found, theoretically, at the

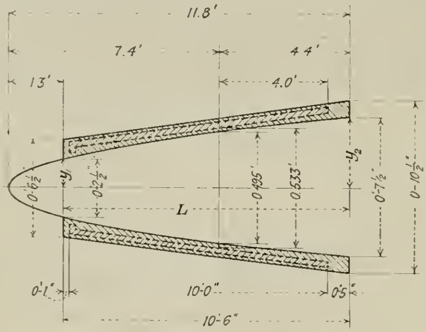

Fig. 2 Rough Centrifugal Casting for Machining to Dimensions Shown in Fig 1

least inclination whose corresponding speed value is just sufficient to carry the metal around in the mold. This theoretical lower limit need not be solved for, however, as requirements of practice naturally demand a higher value, determined experimentally or in regular operation. If we assume that the lowest practical speed for a casting of this type has been set at 400 r.p.m. we may then use the values $a = 121$ and $R = 400/60 = 6.67$, getting thereby the value $\alpha = 13$ deg. inclination. For every value between 13 and 90 deg. there may be found in similar fashion a corresponding speed value lying between 400 and 840 r.p.m., and every correlated pair will produce identically the same shape of casting. (This suggests the somewhat odd conception of the possibility of a rotating mold waving irregularly about during the casting operation without detriment to the shape of the casting, provided only that the rotation be accelerated or retarded in harmony with the gyrations of the apparatus.) It may happen, in case the coefficient a has a low value, that the lowest speed permitted by requirements of practice can be attained or approached only by use of the highest speed allowed by the equation of the bore, i.e., by using the vertical position; a good example of this may be found in the Huth patent.

From the foregoing will be seen the utility of these calculations in the design of equipment. By ascertaining the equation of the parabola that will give to the bore the desired shape, and then by assigning the desired speed or range of speeds of rotation there may be obtained immediately the angle or the range of inclination of axis, which must be known before plans for the casting equipment can be laid out. Conversely, having given the range of speed and the range of inclination of any machine, it is then possible to ascertain whether any particular piece of work will fall within those limits.

Weight of Metal Required

Having found the relations between inclination and speed, it is convenient to find the weight of metal needed to form the casting. This is done by taking the difference between the volume of the mold (frustum of a cone) and the volume of the bore (frustum of a paraboloid) and applying to it the per-unit weight for the metal used. For the case in hand the volume is thus found to be, by well-known formulas, 2.42 cu. ft., which, if the metal weigh 500 lb. per cu. ft., indicates 1210 lb. as the weight needed to make the given casting. Shrinkage may be allowed for in the per-unit weight used. In this connection it is worth while noting that no matter what be the per-unit weight of the material, the control equations are not changed; conditions relating speed, inclination, and shape of bore are the same whether for lead or for aluminum.

As in other matters, many specific cases will be found to have features peculiar to themselves for which special provision must be made. For instance, after ascertaining the equation of the parabola that would fit in with the rough inside diameters assigned in Fig. 2, it would be desirable to find out whether the bore as cast would encroach at any point upon the thickness of extra metal needed for inside finish, owing to the bulging shape of the sides of the parabola. In some cases these factors can be taken care of without calculation, in others it may be necessary to determine the diameters of the rough bore at certain points, or to solve by familiar methods for the slope of the curve (for parabola of form $x = ay^2$ the slope is $1/2\ \sqrt{(ax)}$ or $1/2\ ay$), to compare this slope with the shape of the finished bore at and near the point under examination and then to modify the parabola accordingly if necessary. To illustrate, the slope of the wall of the finished casting (Fig. 1), is $^1/_2(10 - 6)/120$ or 0.0167, corresponding to 0 deg. 57 min., while the slope of the parabola at the large end of the casting, where y has been found to be 0.3125 is $1/(2 \times 121 \times 0.3125)$ or 0.0132, corresponding to 0 deg. 46 min., which being less indicates that there will be at least some encroachment of the kind mentioned. By investigating the amount and the location of this encroachment by a side calculation, it will be found that there remains a finish of $^7/_{16}$ in. on the inside diameter at the most critical point. If this finish is not enough, the lack is made up by taking a smaller inside diameter for either end or for both ends of the rough casting and recomputing the parabola.

Application of Calculations to Long Tubes

Another use to which these calculations could be put is to control the casting of long cylindrical tubes of small diameter, in which there might be some likelihood of the metal not reaching evenly to the far end of the mold before freezing. In cases like this it is evident that the cylindrical shape could be approximated by setting the mold at a slight inclination and driving it at first, during introduction of the metal, at a speed relatively low, thus giving the metal a chance to flow downward, then increasing the speed so as to obtain the near-cylindrical shape. This plan is closely equivalent to the mode of operation in a number of old patents, among them 648,601, Stridsberg, year 1900. By calculating the shape of the bore for the several speeds used this kind of control could be developed quite satisfactorily. Speed requirements for the vertical casting of near-cylindrical shapes may be calculated in a similar way. No illustrations are needed here because the computations are similar to those already described, differing only in their application.

Regulation of Speed or of Centrifugal Force

Reference was made to the fact that calculation of the theoretical lower limit of speed was made unnecessary by reason that requirements of practice demand a higher value. By this is suggested a question upon which there has been a little difference of opinion among various operators of centrifugal casting processes, and since it directly concerns the subject of control a brief analysis of it here should not be out of place. Let us say that in order not to rotate the mold so slowly as to run the risk of spoiling the casting, a certain speed of rotation has been settled upon and accepted as the most favorable one for castings of a certain diameter. It seems pretty well agreed that having been determined for one diameter, this favorable speed condition should be extended, if possibie, for the sake of uniformity in practice, to cover other diameters. In the main, two different means have been adopted in the effort to

(Continued on page 730)

Avoidable Waste in Locomotive Operation as Affected by Design

By JAMES PARTINGTON,[1] NEW YORK, N. Y.

The best way to overcome waste in locomotive operation is to design the locomotive in the first place so that it will fulfill the efficiency requirements of

1 A drawbar horsepower for the minimum amount of fuel

2 A drawbar horsepower for the minimum amount of weight of locomotive and tender

3 A drawbar horsepower for the minimum cost of repairs.

Fuel economy is effected by firebrick arches, superheaters, feedwater heaters, generous steam spaces, automatic stokers, etc. Minimum weight is secured by careful design of the machinery parts, use of special materials, use of the independent booster for special grades. Minimum cost of repairs is dependent on the use of as few bolted parts as possible, accessibility of parts, removability, and interchangeability. Standard replacement parts can be secured from builders.

Much waste in locomotive operation can be avoided by making a careful study of present motive-power equipment, modernizing it where necessary, or replacing it by new equipment.

IT SEEMS advisable to consider this subject from the constructive standpoint of indicating what constitutes good design as demonstrated by locomotives in actual service, rather than to attempt to point out the defects in locomotives which do not show maximum efficiency. If any power plant or engine is not properly proportioned for the work it has to do, the most expert skill in operation can reduce only in part the waste resulting from having such equipment in service.

First, considering the design of steam locomotives from the standpoint of new equipment, when a railroad company is in the market for new locomotives its requirements may be met sometimes by duplicating locomotives in service on their road, but adding newly developed attachments which make for increased efficiency and economy. More frequently, however, it will be found that increased traffic, change from wooden to steel cars, improvement in track, roadbed and bridges, etc., will justify and make advisable the adoption of locomotives of a larger and more powerful type.

Then careful consideration must be given to service requirements —maximum loads to be hauled, capacity of cars, approximate proportion of loaded to empty cars per train, grades, curves, running time over divisions, maximum allowable load per axle, location of coal chutes and water tanks, clearances, conditions under which trains must be started, and any other special requirements of the service.

Having determined the drawbar pull necessary, it remains to design a locomotive that will have the following efficiency requirements:

1 A drawbar horsepower for the minimum amount of fuel

2 A drawbar horsepower for the minimum amount of weight of locomotive and tender

3 A drawbar horespower for the minimum cost of repairs.

Fuel Economy

As standard practice in modern locomotives, a sectional brick arch in the firebox and a fire-tube superheater should be applied as a means of saving fuel in any class of service. A sectional brick arch is low in first cost, easily applied and easily renewed. It usually accomplishes a fuel saving of from 10 to 12 per cent in coal-burning engines, and about 5 per cent in oil-burning engines.

The very general use of superheaters has gradually brought about improved conditions of cylinder lubrication which now make it possible and desirable for the greatest economy to use a high degree of superheat, 250 to 300 deg. now being considered the best practice. A saving of 25 to 30 per cent can be obtained.

[1] Estimating Engineer, American Locomotive Company. Mem. Am. Soc.M.E.

For presentation at the Annual Meeting, New York, December 5 to 9, 1921, of The American Society of Mechanical Engineers. The paper is here printed in abstract form and advance copies of the complete paper may be obtained gratis upon application. All papers are subject to revision.

The use of feedwater heaters will further conserve fuel, and these are now in general use in continental Europe and are gradually being applied to locomotives in the United States. The saving that can be realized is as much as 12 per cent. The initial cost is considerable, but the effect of the feedwater heater in operation, aside from fuel economy, will be to help reduce other boiler-maintenance charges.

The general proportions of the boiler should also receive careful consideration. For the best results with bituminous coal, the length of the boiler tubes should be approximately within the following limits;

Size of tube, in.	Distance over tube sheet
2	18 ft. 0 in. to 19 ft. 6 in.
$2^1/_4$	22 ft. 6 in. to 24 ft. 6 in.
$2^1/_2$	28 ft. 0 in. to 30 ft. 0 in.

For many designs of locomotives, a combustion chamber can be provided, and this will help further in the economical production of steam. A generous steam space should be provided, and the throttle designed and located to secure dry steam. The evaporative capacity of the boiler should be as nearly 100 per cent of the maximum steam requirements of the cylinders as the type of locomotive will permit. Based on 100-per cent boiler, the grate area should be sufficient to prevent the maximum coal consumption per sq. ft. of grate per hr. from exceeding, for bituminous coal, 120 lb., and for anthracite coal, 55 to 70 lb., depending on size.

When the total coal consumption exceeds 6000 lb. per hr., it is generally necessary to apply an automatic stoker. These have now been so adapted to locomotive requirements that a properly designed stoker will show economy over hand firing, aside from the necessity of its use on account of the coal consumption being greater than the physical capacity of one fireman if the boiler were hand-fired.

The arrangement of deflector plates and netting in the smokebox should be carefully adapted to the fuel and combustion conditions, to provide minimum fuel waste and minimum back pressure in the cylinder-exhaust passages with proper provision against fire hazards which might obtain by the throwing of sparks.

The boiler being designed to produce steam at a minimum cost, it is now necessary to design the engine to use this steam with maximum economy.

The cylinder proportions and diameter of the drivers should be such as will develop maximum horsepower at the ruling speeds for train movements. The greatest horsepower of locomotive cylinders will usually be developed within a piston speed ranging from 700 to 1000 ft. per min. Therefore, if other traffic conditions will permit, the operation of trains within these limits should show the greatest operating economy.

Minimum Weight of Motive-Power Equipment

The weight on the locomotive drivers gives an engine friction, independent of other factors, of 22 lb. per ton. The desirability of avoiding excess weight on the drivers from this standpoint alone is therefore readily apparent. When the type of engine will permit, this weight should not exceed what is necessary to give a satisfactory factor of adhesion; this is usually $4^1/_4$ times the maximum tractive power. All weight in excess of this and all other excess weight and excess tender weight should be eliminated, as far as this can be done without detriment to the design of engine and tender. This applies with particular force to the machinery parts of the engine, especially those parts which affect the counterbalance. All saving in weight in these parts usually produces a similar saving in counterbalance weights and a reduction in the dynamic augment, which is very desirable from the standpoint of track and roadbed maintenance.

The use of special materials to keep down weight is often amply justified if repair parts can be obtained promptly when required.

This, in the past, has often been the cause of delay, but it can be guarded against by carrying a few spare parts in stock ready for renewals. High-tensile alloy steel can frequently be used to advantage for driving axles, crank pins, main and side rods, piston rods, etc.

Occasional steep grades or hard starting conditions at stations may cut down the hauling capacity of locomotives over a division to a serious extent. In such cases, the utilization of the weight on trailer trucks for additional tractive power in starting and at slow speeds may increase the capacity of the locomotive from 10 to 25 per cent, depending on the number of driving wheels and working pressure. It has been demonstrated that a separate steam engine or booster geared to the trailing axle will give this additional traction, and that it can be cut in or cut out very satisfactorily as occasion may require.

This is an item in economical operation worthy of consideration where hauling capacity is restricted by such limitations, and the use of an independent booster may often permit the satisfactory operation of considerably lighter locomotives for service of this character.

Within the limits of this paper, only the major features of design can be outlined briefly, and only such devices as have been carefully tried out and are in successful operation are cited. The writer believes the savings mentioned are well within what may be obtained in practice.

Many other improvements promising further economy in the generation and use of power in the steam locomotive are contemplated and in the experimental stage, but these do not properly come under the scope of our subject as here treated.

Cost of Repairs

It has been pointed out that locomotives and tenders should be designed to produce the required drawbar horsepower with as little excess weight as possible. In this connection, however, due consideration must be given to the question of repairs.

The design of boilers from the standpoint of weight is practically fixed by existing boiler regulations, which provide that locomotive boilers must be operated with a factor of safety of not less than four. Practically all boilers at the present time are designed with a factor of safety of $4^1/_2$, which leaves a comfortable margin between this and the minimum allowable operating factor.

The maximum stresses in other parts of the locomotive must also be carefully considered, and the parts must be designed to keep these stresses within limits which will eliminate costly failures in service.

Aside from the consideration of stresses, much repair cost can be avoided by adopting designs which reduce the number of parts, as far as reasonably may be, especially where these parts must have bolted connections. Here, however, care must be taken to avoid construction which cannot readily be removed for repairs or renewals or repaired in place with reasonable facility.

Many roads today are giving a great deal of thought to locomotive design along these lines, having especially in mind the desirability of making the engine parts:

- Accessible for oiling and inspection
- Easily removable with proper shop facilities
- Of the minimum number of pieces
- Interchangeable with equipment now in service.

The repair-shop facilities must, of course, be kept abreast of the requirements; i.e., as new and larger locomotives are put in service, turntables, cranes, machine tools, etc. must be of sufficient capacity to handle the larger equipment economically.

The repairs of locomotives can often be facilitated and the necessary shop equipment kept down to the minimum by securing from the locomotive builder many parts which he is able to turn out more accurately and more economically than the average railroad shop would be equipped to do. Such parts include:

- Flanged sheets for boiler repairs
- Flexible and ordinary staybolts
- Finished bolts and nuts
- Drop forgings
- Packing rings for pistons and piston valves
- Special equipment which requires special tools for its production.

Without attempting to pursue further the design of new locomotives it may be remarked that a study of the special conditions of individual railroads is necessary to secure equipment best suited to the needs of each.

Old Motive-Power Equipment

Much waste in locomotive operation can be avoided by making a careful survey of present motive-power equipment which is not giving as economical or efficient service as could be obtained if the engines were modernized. This applies particularly to locomotives where the service conditions demand more power than the present equipment can economically produce. All the suggestions made in regard to the design of new equipment are applicable to a greater or less degree to old equipment, providing the old equipment is not meeting the demands of the service from a power standpoint, or is not furnishing this power economically.

In making a survey of this character care should be taken to determine accurately whether the old equipment will warrant the additional cost of changes and betterments necessary to convert it into up-to-date power. This can be decided by taking the number of years the engines will be retained in service and the increased net return or saving for this period as against the cost involved for changes, interest on the additional investment, increased maintenance, etc.

A comparison should also be made with the results that could be realized by the purchase of new equipment best adapted for the service, as against the cost of contemplated changes in the old equipment.

If these comparisons show a saving in favor of modernizing the old equipment or the purchase of new equipment, every month that the engines are kept in service without doing this will result in a loss that is not recoverable. A few concrete examples of what has been accomplished in service by locomotives designed to yield maximum efficiency may be of advantage. Notable designs, for which data is available, are as follows:

- Pacific type passenger locomotive No. 50,000 built by the American Locomotive Company
- Decapod type freight locomotive, Class I1s, built by the Pennsylvania Railroad Company
- Heavy Mallet special service locomotive built for the Virginian Railway by the American Locomotive Company.

The full paper gives performance records of these three engines.

CONTROL OF CENTRIFUGAL CASTING BY CALCULATION

(*Continued from page 728*)

bring about such uniformity, and these are, first, to so regulate the speed in r.p.m. as to hold the peripheral speed at a constant figure, or, second, to so regulate it as to hold the centrifugal force at a constant figure, for all diameters. A third plan is to so regulate the speed as to keep at a constant figure the tensile stress, regarding the casting as the rim of a flywheel, which it resembles in certain respects as soon as solidification has gone far enough to allow shrinkage to begin to draw the casting in, away from the sides of the mold. If the first plan is examined, it will be seen that the r.p.m. must vary inversely as the diameters; in the second plan, on account of the nature of centrifugal force, the r.p.m. will have to vary inversely as the square roots of the diameters; the third plan figures out like the first. The second set of conditions is therefore irreconcilable with either of the other two, which indicates that any effort to find conditions under which the metal of similar castings of different diameters would be subjected to identical physical forces is likely to be a prolonged one.

Conclusion

In closing it may be observed that possibly some foundrymen will look askance at what may seem so far from sand and patterns; they may rest assured, however, that what has been set down here is of an entirely practical nature in the field within which it applies, and that once understood in principle the calculations described do not offer the difficulty nor require the time that might be anticipated on first reading.

Making Work Fascinating as the First Step Toward Reduction of Waste

By WALTER N. POLAKOV,[1] NEW YORK, N. Y.

Confusion of classes of life has resulted in building up of industry around the mistaken idea that workman is an animal and his work a commodity.

Personnel administration, employment and compensation methods recognizing the human nature of workers have failed in so far as they have either concentrated their efforts on the functions outside of the work itself or attempted to stimulate the animal instincts alone.

Such experiments as have been already conducted in uniting brain work with manual work have proved beyond any doubt that such a course liberates dormant or suppressed creative capacities of men and not only improves quality and quantity of production but, above all, substantially ameliorates industrial relations. As to the parties to industry, the advantage to be derived from such an industrial organization that brings mind into labor and makes work fascinating, are at once beneficial to owner group and to the labor group.

Owners thereby develop a steady, contented, intelligent and highly productive personnel, thus eliminating a major part of past and present embarrassments, conflicts and losses. The labor group simultaneously frees itself from the oppressive feeling of drudgery of work, satisfies its human consciousness, secures opportunities for intellectual and technical advancement and improves its material status.

Management for the first time in history attains a position of dignity and stability, since its prime function becomes that of the liberation and direction of human, creative functions instead of partially utilizing only the physical power of men.

INCREASED production has been sought by devising labor-saving machinery and by stimulating individual productivity of workers. The first method, while in itself productive of results, rapidly and inevitably developed two by-effects which greatly reduced the advantages anticipated: (*a*) Automatic high-speed machinery, sold at a high price, increases overhead often in excess of reduction in payroll, materially increasing the capital charges on manufacturing establishments; (*b*) automatic, semi-automatic, high-speed and single-purpose machinery of modern industry makes the work of its attendants monotonous because it lacks the stimulating interest furnished by work requiring exercise of the mental faculties. The general consequence of both these tendencies has been toward increased cost of production instead of expected reduction of expenses. In times of industrial depression, idle expensive equipment greatly increases the cost of ownership. The workers, on the other hand, failing to get stimulation and satisfaction from work as mere parts of automatic machinery, demand shorter hours of this drudgery and higher compensation with which they can buy the interest, stimulation and pleasure which they fail to find in the work itself.

The task before the engineer of today is to overcome the ill effects of automatization and mechanization of industry. The world needs the highest possible production and the workers demand creative self-expression in industry.

This obviously cannot be accomplished by scrapping existing machinery or putting a ban on further inventions and improvements, for such digression will not only throw us further back in output, but is contrary to the nature of mankind. Therefore, the solution will be sought in the development of means of abolishing the industrial monotony and drudgery of work by introducing into it intelligent, self-expressive, creative motives. The problem thus resolves into one of *making work fascinating* as a means of releasing the desire to work.

The early attempts to make workers personally more efficient are generally connected with the Taylor system of management. The characteristic features of this system are (*a*) specialized division of function, and (*b*) detailed time studies of operation. A score of years of trial of this system has clearly demonstrated its inherent, organic shortcomings in many industrial establishments. (*a*) Functional foremanship, with brain work divorced from manual work has made the performance of work still more automatic and irresponsible. Creative, intelligent work has also been removed from the shops themselves and concentrated in a planning department or general office, which lacks direct personal touch with workers. (*b*) Time studies and instruction cards, by standardizing workers' manipulations, have caused the operations to become still more monotonous, repetitive without variations and devoid of stimulative self-expression.

Time studies, motion studies and other means of studying the work are in themselves commendable as steps toward substitution of "guess" and "opinions" by measured *facts*. Unfortunately, however, all these means lead to standardization and mechanization of manipulations. Once man is lowered to the level of an automaton, the creative element is driven out of his work and subsequent difficulties are impending. Again, *while* the studies are being made, a healthy, stimulating interest in the work is aroused, especially if workers' coöperation is invited; but once completed, tabulated, registered and prescribed, they become a monotonous routine. Vigorous protests and even some legislation against this dehumanizing application of scientific methods in an unscientific manner have been the inevitable results.

Recognition of these fatal mistakes has prompted industrial engineers to concentrate on the shortcomings of management itself. These efforts have (1) decentralized the detached intelligence of the planning department by establishing manufacturing offices in the shops, (2) reunited the instructing and inspecting functions of foremanships, (3) substituted for time-study clerks the direct interchange of worker's skill and intelligence, (4) stimulated interest in the work by training and providing instruments for intelligent control of processes, (5) liberated the suppressed creative instincts of workers by providing them with means for observing their own progress, and, finally, (6) devised a charting method permitting the accurate measurement of managerial efficiency separately from the efficiency of workers.

Until recently the acceptance of one or another managerial policy was a matter of personal opinions or sympathies. The error of applying to the workingmen the rules and measures which take into account *only* their animal functions is that of confusing the part with the whole, inasmuch as the physical labor of men is but a part of their nature. This blunder, therefore, is even more fatal in industrial relations than a similar confusion of dimensions would be in mechanical construction.

On the other hand, the strength and correctness of our principle is in its recognition of the time-binding nature of men and consistent provisions for exercise on the part of workers of their *human*, creative functions together with liberation of purely mechanical work.

For some time past weariness of spirit and dissatisfaction with brutalizing monotony of work not only has made the workers in this country as well as abroad restless and irritable, but also has moved them to demand short hours and high pay for drudgery, while the quantity and quality of personal output has sometimes decreased in spite of concessions made.

This failure to recognize true human nature and its fundamental natural power constantly and forcibly seeking self-expression is the basic cause of the alarming extent of industrial waste. The report recently made by the committee of The Federated American Engineering Societies telling of waste in life, health, welfare and wealth caused by business and industry emphasized that: "From this knowledge will grow the certain vision that *mental and moral forces must be added* to the physical resources now employed, if industry is to serve all." It is significant that our losses are primarily due to the application of animal standards to human creative activities in industry.

[1] Consulting engineer, Walter N. Polokov & Co., Inc. Mem.Am.Soc. M.E.

For presentation at the Annual Meeting, New York, December 5 to 9, 1921, of The American Society of Mechanical Engineers. The paper is here printed in abstract form. All papers are subject to revision.

For some time past studies of industrial fatigue have attracted widespread attention both in this country and abroad. It has been proved by various investigators that a great deal of waste in production is due to unnecessary fatigue, as distinguished from allied factors. Moreover, while mere physical fatigue gives to the man unmistakeable warning, thus preventing physical breakdown, and recuperation is rapid and complete, the nervous and mental fatigue accumulates unnoticed.

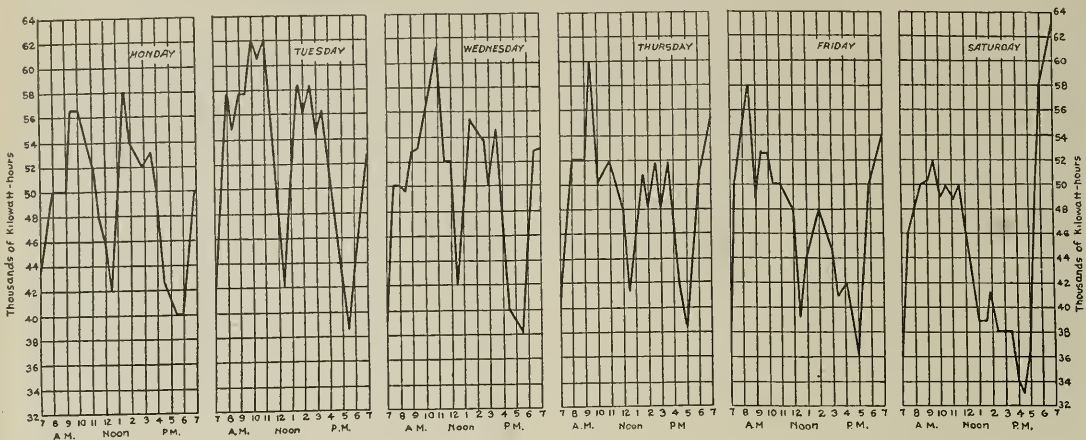

Fig. 1 Relation Between the Accumulation of Fatigue and Drop of Industrial Efficiency

Data collected by the author from records of public utilities supplying power to a variety of industrial establishments, averaging 52 Mondays, 52 Tuesdays, etc., and making a composite average load curve.

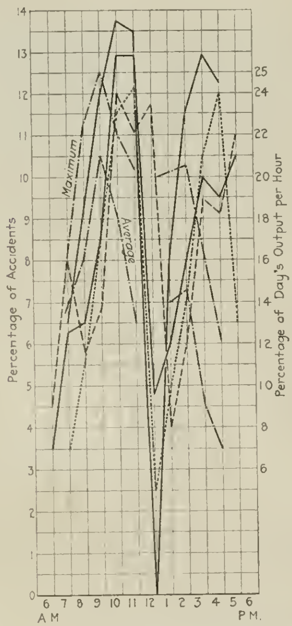

Fig. 2 Effect of Fatigue on Time and Frequency of Industrial Accidents (Due to Carelessness) and Power Used During Preceding Periods

Accidents follow production peaks in four different industries. Data collected at London docks and by several insurance companies in the United States; compiled by Chas. S. Myers, director of the Cambridge Psychological Laboratory.

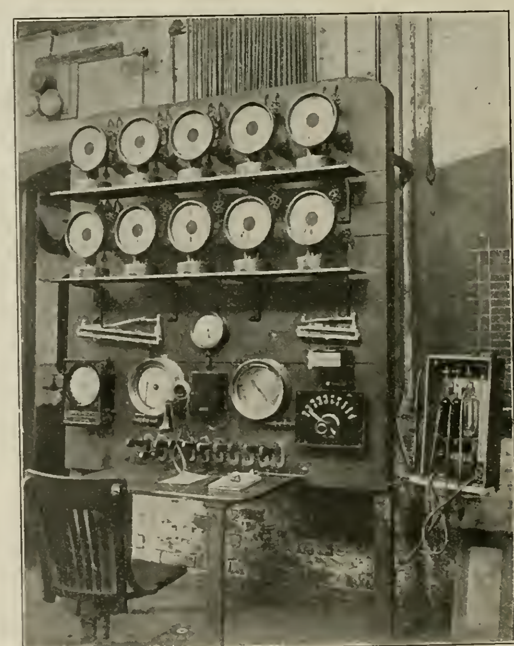

Fig. 3 Instrument Boards in Boiler Rooms Used for Intelligent Control of Processes, Largely Substituting Mental Work for Physical Exertion of Firemen and Providing Interest

that necessary for performance of work under the most favorable conditions. An even more important finding, however, is that physical fatigue itself is largely traceable to mental and nervous fatigue produced by the monotony of repetitive operations and

In this connection the elimination of monotony and the provision of mental and emotional stimuli, making work at least in a measure fascinating, is the fundamental requirement for reduction of such industrial wastes as irregular attendance, large labor turnover,

irritability of workers, inattentiveness, susceptibility to accidents, poor workmanship, high percentage of spoilage, low individual output, etc. Fig. 1 visualizes the well-established relations between

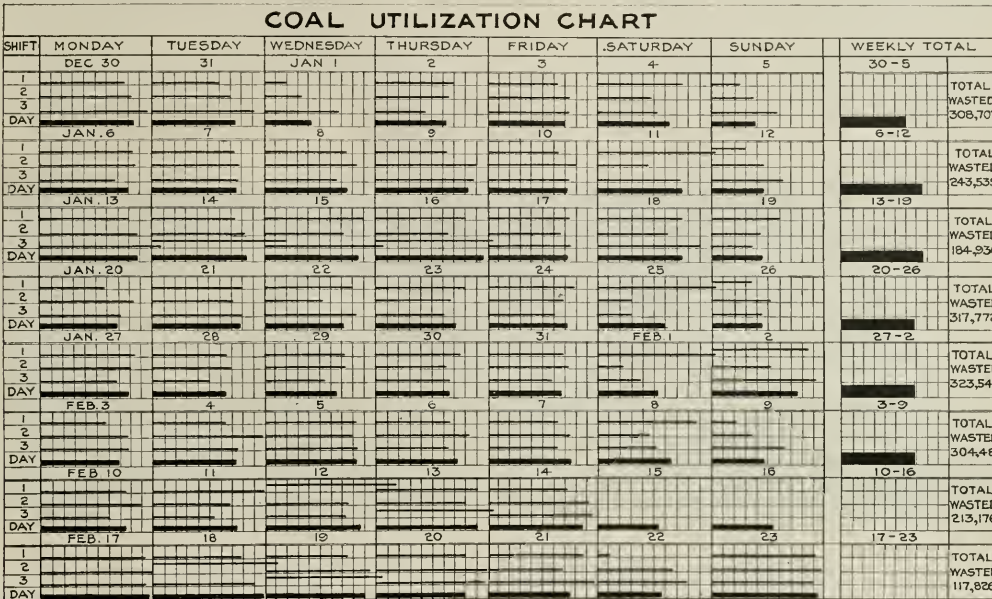

Fig. 4

Based on efficiency obtained by each gang for each day. If efficiency is below 72 per cent the bars on the chart are proportionately short; if efficiency is higher than 72 per cent the bars are doubled up. Note the progress in elimination of waste from January 1919 to January 1921 on chart in Fig. 6.

the accumulation of fatigue and depreciation of industrial efficiency. Fig. 2 illustrates the effect of fatigue on the rate of industrial accidents, as well as relation to hourly outputs.

Even the most advanced employment methods alone are impotent to solve this problem, for they deal with men and working conditions *as they are*. If conditions be poor, only poor men can be selected to endure them. This means waste of productive power and a premium of steady employment to the least efficient producers. The personnel executives in their attempt to ameliorate these

shortcomings have dealt however with only one side of the situation: not being engineering executives thoroughly versed with the processes and performance of work, it has remained outside of their jurisdiction to readjust jobs themselves so that workers can derive joy and satisfaction from performing the work.

It would be a mistake, however, to think that repetitive, monotonous operations lack fascination to every one. In fact, there are certain individuals who can best express themselves by performing a well-standardized operation. They find a delight in mere mechanical functions least interfering with an independently occupied mind wandering away from the job. This *imitative* type of men should never be confused with the *creative* type, and the selection of men and women should be practiced along these lines. As to the means of making work fascinating to either type, these are as different as the types themselves.

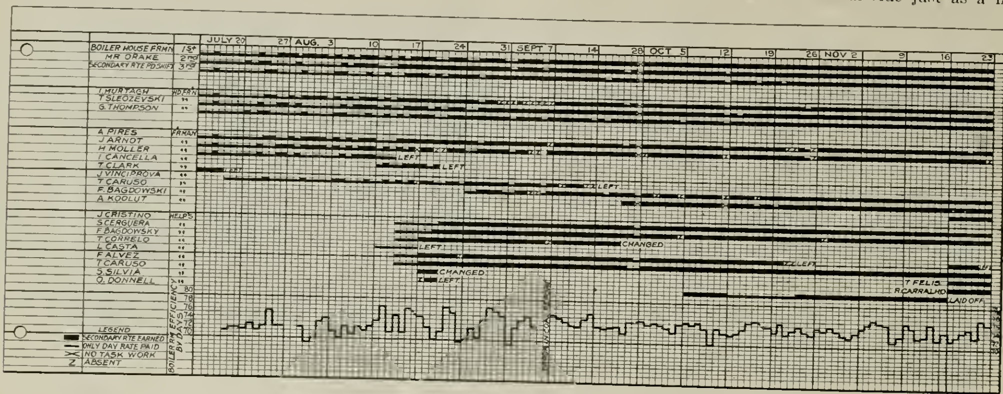

Fig. 6 Coal-Utilization Chart

Showing progress of rapid learning from the beginning of the introduction of the new method.

Instinctively feeling that at the bottom of many labor troubles the monotony of animal-like work is to be found, a large number of manufacturing concerns have adopted a policy of diverting the attention of workers from the shortcomings of working conditions to the refreshing activities of "welfare" work. Some welfare organizations render their assistance in many industrial centers by establishing their Industrial Departments under the direction of men proficient in games. While a measure of success has been recorded in several instances, this movement is obviously directed along the wrong course. It attempts to *divert the attention from work to recreation.*

Incentives to higher production, so far as workers are concerned, have been offered, both financial and non-financial. To the first group belong a variety of such forms as profit sharing, differential piece rates, incentive payments, etc.; in the second group the non-financial incentives of Wolf stand alone. As a means for securing the interest of workers in the work itself, these incentive payments are obviously unfit, for they merely create interest in securing a larger pay. The work itself, in so far as it is spurred and speeded up by anticipation of a monetary premium, becomes still less attractive. If workers were left to themselves to devise more efficient productive methods to attain offered reward, these financial incentives could prove their human worth as mental stimuli for attaining perfection, were it not for the fact that neither workers nor their immediate leaders have sufficient technical training and research facilities to develop more efficient practice without the aid of specialists.

Non-financial incentives, on the other hand, have demonstrated the value of an environment which stimulates thinking. By having opportunity to constantly increase their knowledge of the underlying natural laws of the process, the workers are able to realize the joy which comes from a conscious mastery of their part in any process.[1] The creative activity is the final aim of human beings, yet to preserve life we must not only provide the material requisites of food, clothing and shelter, but meet also the higher demands of human life commensurately with the degree of culture and service rendered. Greater service rendered is both conditioned and followed by greater material reward. It is *conditioned*, inasmuch as a man who is kept by material limitations on a low level of hygiene, comfort, education and refinement cannot produce higher values in his work. It is *followed*, in so far as the higher development of man's creative power is capable of producing greater values. The nature of man involves the material side just as a higher dimension contains a lower. Consequently any wage system, in order to comply with human nature, should not confuse incentives for acquisitive passion with adequate provisions enabling wage earners to reach a higher plane of cultural and productive development. This aim can be attained by a two-rate wage[1] as developed and practiced by the author; it substantially consists of a fixed

(Continued on page 765)

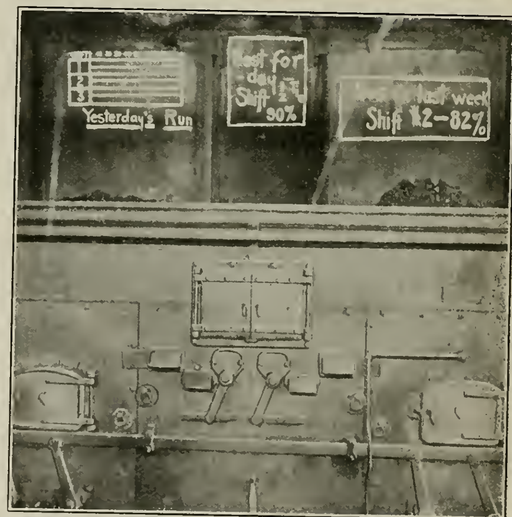

Fig. 7 Man-Record Chart Drawn on Front of Boilers and Score Recorded by Men When Work Has Lost Its Monotony

The full length of space means expected economy (72 per cent boiler and stoker efficiency); short lines indicate falling short of full efficiency. Accordingly 90 per cent means about 65 per cent efficiency of boilers.

Economies Obtainable by Reducing Resistances in Steam Piping

By O. DENECKE

DISCUSSION of the general principles on which the design of steam piping in power plants should be based, with comparison of formulas suggested for various elements affecting steam consumption as a function of resistances encountered to the flow of steam. The following notation is used:

Notation in Original	Notation in This Abstract	
Q	Q =	weight of steam discharged from a pipe or passage, kg. per hr.
Q'	q =	weight of condensation in the steam piping, kg. per hr.
l	L =	length of steel piping, meters
d_{cm}	d =	diameter of piping, cm.
p_1	p =	steam pressure at exit, kg. per sq. m.
p_2	P =	steam pressure at entrance into piping, kg. per sq. m.
Δ	l =	total pressure loss in piping, kg. per sq. m.
Δ_R	r =	pressure loss in piping due to friction, kg. per sq. m.
R	R =	$r \div L$ pressure loss through friction in piping per meter of length of pipe
β	b =	coefficient of friction in the piping
ζ	k =	coefficient of resistance for individual resistances
Z	Z =	Σlk = pressure loss in all the single resistances, kg. per sq. m.
γ_w	w =	average specific weight of steam at $P_1 = (p + P) \div 2$, which is the average steam pressure in the piping, kg. per cu. cm.
v	v =	average steam velocity, m. per sec.

I *Pressure Loss Due to Friction Only.* For conditions considered here the formulas

$$r = \frac{1.251\,bL}{wd^5}\left(Q + \frac{q}{2}\right)^2 \qquad [2]$$

and—since

$$\left(Q + \frac{q}{2}\right)^2 = Q^2\left(1 + {}^1/_2\,\frac{q}{Q}\right)^2 = Q^2\left(1 + \frac{q}{Q}\right)$$

$$r = \frac{1.251\,bL}{wd^5}Q^2\left(1 + \frac{q}{Q}\right) \text{ in kg. per sq. m.} \qquad [3]$$

taken from the German engineering handbook Hütte (22nd edition, vol. 1, p. 449), are sufficient.

The same handbook gives the values for the coefficient of friction, b, as a function of the weight of the steam, Q, as indicated in Table 1.

TABLE 1

Q	b	Q	b	Q	b	Q	b
10	2.03	100	1.45	1000	1.03	10,000	0.73
15	1.92	150	1.36	1500	0.97	15,000	0.69
25	1.73	250	1.26	2500	0.90	25,000	0.64
40	1.66	400	1.18	4000	0.84	·40,000	0.595
65	1.54	650	1.10	6500	0.78	65,000	0.555
100	1.45	1000	1.03	10000	0.73	100,000	0.520

On the other hand, however, Fischer and Gutermuth have adopted a constant value $b = 1.5$ and obtained the formula

$$r = \frac{1.878\,L}{wd^5}Q^2\left(1 + \frac{q}{Q}\right) \qquad [3b]$$

extensively used for low-pressure steam-heating calculations.

Eberle recommends for high-pressure piping a constant value $b = 1.05$, which gives the formula

$$r = \frac{1.31\,L}{wd^5}Q^2\left(1 + \frac{q}{Q}\right) \qquad [3c]$$

The present author derives from Equation [3] an expression for pressure drop per running meter of pipe:

$$R = \frac{r}{L} = \frac{1.251\,L}{wd^5}Q^2\left(1 + \frac{q}{Q}\right) \qquad [4]$$

which may be also expressed in the following form more convenient for slide-rule calculations:

$$R = \frac{1.251\,b}{wd^5}\left(\frac{Q}{d^2}\right)^2\left(1 + \frac{q}{Q}\right) \qquad [4a]$$

and also:

$$d^5 = \frac{1.251\,b\,Q^2}{wR}\left(1 + \frac{q}{Q}\right) \qquad [5]$$

II *Pressure Loss Due to Individual Resistances.* (Changes of direction, cross-section of piping, bends.) Each individual resistance occurring at any point x in the piping creates a loss of pressure expressed by

$$lk_x = k\frac{v^2_x}{2g}\,w_x \qquad [5a]$$

which, with Q_x substituted for v_x, becomes

$$lk_x = \frac{0.64\;Q^2_x}{w_x d^4} \qquad [6]$$

where k_x is the coefficient of resistance, the values of which are given in the German Hütte (vol. 3, pp. 415 and 419), as ζ_v.

For the ranges of pressure which have to be considered in connection with ordinary power-plant design, and for all the individual resistances (k_1, k_2, k_3, etc.), one may with sufficient precision substitute for w_x its average w and hence write $Q_x = Q + \frac{q}{2}$, so that the total pressure drop across all the individual resistances together (Σk) is

$$Z = \Sigma lk = \frac{0.64}{wd^4}\left(Q + \frac{q}{2}\right)^2 \text{ or}$$

$$Z = \frac{0.64}{wd^4}\left(1 + \frac{q}{Q}\right)\Sigma k \qquad [7]$$

or

$$Z = \frac{0.64}{w}\left(\frac{Q}{d^2}\right)^2\left(1 + \frac{q}{Q}\right)\Sigma k \qquad [7a]$$

If a substitution be made here from Equation [4] we obtain

$$\frac{Q^2\left(1 + \frac{q}{Q}\right)}{wd^4} = \frac{dR}{1.251\,b}$$

and hence

$$Z = \frac{0.51}{b}\,d\Sigma kR \qquad [8]$$

This latter, with $b = 1.5$, in accordance with Fischer, gives the following expression suitable for low-pressure steam piping:

$$Z = \frac{d}{3}\,\Sigma kR \qquad [8a]$$

and with $b = 1.05$, according to Eberle,

$$Z = \frac{d}{2.06}\,\Sigma kR$$

Since, however, the values of k and b are somewhat uncertain for

dinary calculations of high-pressure piping, the following equa-
on may be used:

$$Z = \frac{d}{2}\Sigma kR$$

III *The Total Drop in Pressure* through friction and individual sistances in the entire length of pipe L is

$$l = P - p = r + Z$$

hich with values for r and Z substituted from Equations [4] and] becomes

$$l = RL + R\frac{0.51}{b}\,d\Sigma k$$

$$l = R(L + \frac{0.51}{b}\,d\Sigma k) \ldots\ldots [9]$$

$$l = R(L + Lk) \ldots\ldots [10]$$

$$Lk = \frac{0.51}{b}\,d\Sigma k \ldots\ldots [11]$$

In these expressions the individual resistances are replaced by ngths of piping which by friction produce the same drops of essure as the respective resistances. Hence, for each $k = 1$ will be necessary to increase the piping by a length equal to:) for low-pressure piping (according Equation [8*a*]), $d/3$ meters, d (*b*) for high-pressure piping (according to Equation [8*b*] for dinary calculations), $d/2$ meters, or more correctly $0.51\,\frac{d}{b}$ eters, where b has the value given Fritzsche; the piping so ngthened should then be computed with respect to its frictional sistance. Thus, for example, if the pipe diameter is 49 mm. then each $k = 1$ it should be increased in length for purposes of culation in the case of low-pressure steam by $4.9/3 = 1.63$ eters, and for high-pressure piping by $7.35/3 = 2.45$ meters. This method of calculation has the advantage of simplicity and se of remembrance.

IV *Methods of Application* of the above equations for the solution the problem: How to reduce, by decreasing the individual sistances, the pipe diameter, and hence the cost of pipe installa-n. There are given Q, L and the permissible pressure drop $l = -p$, and it is desired to find the proper pipe diameter for ch Σk.

(*a*) $\Sigma k = 0$ gives the smallest possible diameter d_o, since then the tire pressure drop l is due exclusively to friction. Since $Lk = 0$, have according to Equation [10], $l = R(L + Lk)$

$$R_{\Sigma k=0} = R_o = \frac{l}{L} \ldots\ldots [11b]$$

d according to Equation [5]

$$d^5 = \frac{1.251\,bQ^2}{wR}\left(1 + \frac{q_o}{Q}\right) \ldots\ldots [12]$$

ere q_o gives the amount of condensate per hour for the smallest meter d_o. As q_o in well-insulated piping amounts to only a v per cent, the member $1 + \frac{q_o}{Q}$ has scarcely any influence on d d may be either neglected entirely or merely estimated.

(*b*) For any other magnitude of Σk a diameter $d > d_o$ has to be und, as in that case only part of the total drop of pressure l is due friction. From Equations [4] and [10], it follows that

$$\frac{l}{L + Lk} = R\frac{1.251}{wd^5}Q^2\left(1 + \frac{q}{Q}\right) \ldots\ldots [13]$$

ile from Equations [4] and [11*b*] we find

$$\frac{l}{L} = R_o = \frac{1.251\,b}{wd_o^5}Q^2\left(1 + \frac{q_o}{Q}\right) \ldots\ldots [14]$$

dividing [13] by [14], we get

$$\frac{d^5}{d_o^5} = \frac{L + Lk}{L}\,(1 + \frac{q}{Q})/(1 + \frac{q_o}{Q}) \ldots\ldots [14a]$$

it since it may be assumed with no great inaccuracy that $+\frac{q}{Q} = 1 + \frac{q_o}{Q}$ and since further according to Equation [11], $Lk = \frac{0.51\,d}{b}\Sigma k$, the above equation becomes:

$$\left(\frac{d}{d_o}\right)^5 = 1 + \frac{Lk}{L} = 1 + \frac{0.51\,d}{bL}\Sigma k \ldots\ldots [15]$$

Therefore, if the minimum pipe diameter d_o has been computed according to Equation [12] for $\Sigma k = 0$, the diameter d for any other value of Σk may be found from the equation

$$\frac{d}{d_o} = \left(1 + \frac{0.51}{bL}\Sigma k\right)^{\frac{1}{5}} \ldots\ldots [15a]$$

or, more conveniently, for any pipe diameter $d > d_o$, the following holds good:

$$\Sigma k = \left[\left(\frac{d}{d_o}\right)^5 - 1\right]\frac{bL}{0.51\,d} \ldots\ldots [16]$$

(*c*) Numerical example. Given:

Q = 3400 kg. superheated steam flowing per hour
L = 50 m., length of piping
p = 9 atmos. = 90,000 kg. per sq. m., final steam pressure at end of piping
P = 9.6 atmos. = 96,000 kg. per sq. m., initial steam pressure

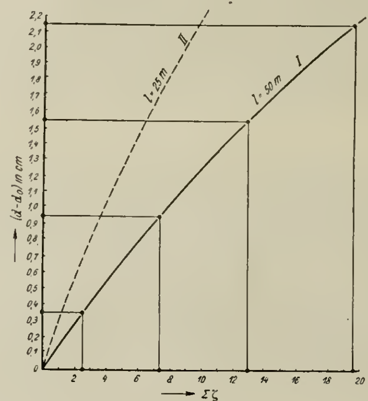

FIG. 1 CURVE SHOWING THE VALUE OF PIPE DIAMETER d AS A FUNCTION OF THE SUM OF INDIVIDUAL RESISTANCES Σk

(Note: 2,3; 2,1; etc. on the drawing mean decimal fractions 2.2, 2.1, etc.)

p_m = 9.3 atmos., = 93,000 kg. per sq. m., average steam pressure for an average steam temperature of 300 deg. cent.
w = 3.51 kg. per cu. m.
l = $P - p$ = 6000 kg. per sq. m., total pressure drop through the piping

$$R_o = \frac{l}{L} = \frac{6000}{50} = 120 \text{ kg. per sq. m., pressure drop per meter}$$

length of pipe.

According to Table 1 (Fritzsche) for $Q = 3400$ kg. per hr., $b = 0.864$ and according to Equation [12] for $\Sigma k = 0$, the minimum diameter is

$$d_m^5 = \frac{1.251\,bQ^2}{wR_o} = \frac{1.251 \times 0.864}{3.51 \times 120}(3400)^2\; d_o = 7.90 \text{ cm.} \ldots [12]$$

The nearest commercial pipe size is $d = 8.25$ cm., and hence $\frac{d}{d_o} = \frac{8.25}{7.90} = 1.044$, which gives

$$\Sigma k = \left[\left(\frac{8.25}{7.90}\right)^5 - 1\right]\frac{0.864 \times 50}{0.51 \times 8.25} = 2.49 \ldots\ldots [16]$$

The next larger commercial pipe diameters according to Equation [16] give

$$d = 8.85, \text{ hence } \frac{d}{d_o} = \frac{8.85}{7.90} \text{ and } \Sigma k = 7.3$$

$d = 10.05$, hence $\frac{d}{d_o} = \frac{10.05}{7.9}$ and $\Sigma k = 19.60$

These diameters d, or rather the differences $d - d_o$, plotted as ordinates (scale 10 to 1) with the values of Σk as abscissæ (scale 1 = 1 cm.), give curve 1, (Schmidt), Fig. 1. This shows how with the decrease of the individual resistances Σk the pipe diameter should be reduced and also permits figuring out the percentage of saving in cost of piping.

It should be noted though that the magnitude of the relative saving is affected not only by k but also materially by the length of the piping L, so that actually the guiding magnitude is the ratio $\frac{\Sigma k}{L}$, that is, the share of the total of the individual resistances for a unit length of pipe, or, say, 1 m. The smaller the value of L with the same $R_o = \frac{l}{L}$, the smaller according to Equation [16] will be the respective value of Σk for any given pipe diameter; therefore the curve will be steeper and the saving in pipe diameter with every reduction of Σk will be greater.

Thus, if in the above example, L have a value of 25 m. instead of 50 m., the values of Σk as computed from Equation [16] would have been only half as large, and instead of curve I in Fig. 1 we should have obtained curve II, which is much steeper. The shorter, therefore, the length of the piping, for example, between boiler and steam engine, the more the individual resistances, (such, for example, as the indispensable valves) increase the cost of piping by affecting its diameter.

V *General Solution.* The solution may be expressed in still more general terms, so that a single curve will suffice for all possible values of Q, L and l, for both saturated and superheated steam. In such a curve all that will be necessary will be to change the scale of abscissæ in order to read off the necessary pipe diameter under all possible kinds of operating conditions, the curve giving at once the diameter of pipe which becomes necessary through the decrease or increase in individual resistances.

If we multiply Equation [16] on its right-hand side by $\frac{d_o}{d_o}$ we obtain

$$\Sigma k = \left[\left(\frac{d}{d_o}\right)^5 - 1\right]\frac{bLd_o}{0.51\, d\, d_o} \quad \ldots\ldots\ldots\ldots [16c]$$

which gives

$$\frac{0.51\, d_o}{bL}\Sigma k = \left[\left(\frac{d}{d_o}\right)^5 - 1\right]\frac{d_o}{d} \quad \ldots\ldots\ldots\ldots [16d]$$

In this case the right-hand side is a function only of $\frac{d}{d_o}$ and is therefore independent of Q, L and l. If further, we equate on the left-hand side

$$\frac{0.51\, d_o}{bL}\Sigma k = x \ldots\ldots\ldots\ldots\ldots\ldots [17]$$

we obtain

$$x = \left(\frac{d}{d_o}\right)^4 - \frac{d_o}{d} \ldots\ldots\ldots\ldots\ldots\ldots [18]$$

which is an equation giving a curve suitable for all kinds of conditions and one that can be easily plotted with properly selected values of $\frac{d}{d_o}$.

Thus, $\frac{d}{d_o}$	x
1	=0
1.05	=0.263
11.1	=0.555
1.2	=1.241
1.3	=2.087
1.4	=3.127

Fig. 2 gives a curve plotted with these values of $\frac{d}{d_o}$ as ordinates (scale $0.1\frac{d}{d_o}$ = 5 cm.) and of x (scale 1 = 10 cm.) as abscissæ.

The following considerations may assist in making use of this curve. Assume that we have given Q, L and $P - p = l$ and hence also $R_o = \frac{r}{L}$. Knowing Q, we obtain from Table 1 the value of b, and further knowing $P - p$ we can obtain $p_m = \frac{P+p}{2}$ and hence w. Equation [12] gives then

$$d^5_o = \frac{1.251}{wR}Q^2\left(1 + \frac{q_o}{Q}\right) \ldots\ldots\ldots\ldots [18a]$$

Here, in the case of superheated steam, $q_o = 0$, while in the case of saturated steam with well-insulated piping, we may set $\frac{q_o}{Q} = 0.02$. Further, for $\Sigma k = 1$, we obtain from Equation [17] the value

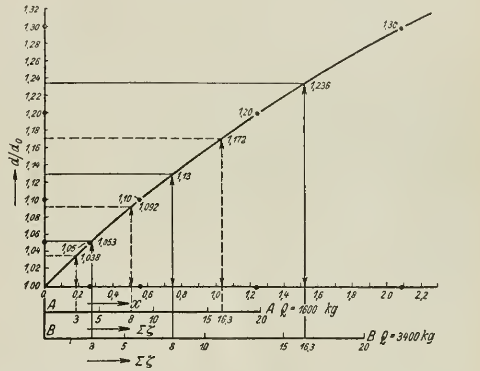

Fig. 2 Curve Showing Ratio $\frac{d}{d_o}$ as a Function of $x = \frac{0.51}{bl} d_o\Sigma k$

(1,32; 1,3; etc. mean decimal fractions 1.32, 1.30, etc.)

$$x_{\Sigma k=1} = 0.51\frac{d_o}{bL} \ldots\ldots\ldots\ldots\ldots\ldots [19]$$

which may be used as a unit in dividing the axis of abscissæ in the curve shown in Fig. 2.

As an illustration of the foregoing we may use a numerical example in which the following values are given: L=0 m.; p = 9 atmos.; P = 9.6 atmos., hence p_m = 9.3 atmos., and w = 3.51 kg. per sq. m.; $R_o = \frac{r}{L} = \frac{6000}{50}$ = 120 kg. per sq. m. Required the pipe diameters for Σk = 3, 8 and 16.3, respectively, these values corresponding to three different types of valves in the piping.

(*a*) Q = 1600 kg. per hr. According to Table 1, b = 0.963, and according to Equation [12]

$$d_o{}^5 = \frac{1.251 \times 0.963}{3.51 \times 120} = 1600^2$$

$$d_o = 5.947 \text{ cm} \ldots\ldots\ldots\ldots\ldots\ldots [20]$$

Further, from Equation [19] we have

$$x_{\Sigma k=1} = \frac{0.51 \times 5.947}{0.963 \times 50} = 0.0633 \ldots\ldots\ldots [21]$$

and hence, if we select as a scale of abscissæ x = 1 = 10 cm., the scale for the new axis of k indicated as $A - A$ and located below and parallel to the original axis of abscissæ will be

$$\Sigma k = 0.0633 \times 10 = 0.633 \text{ cm.} = 1 \ldots\ldots [22]$$

Similarly other abscissæ may be located.

With this subdivision of the axis of k ($A - A$), the following ordinates of the curve are found for the respective values of abscissæ:

$$\Sigma k = 3\frac{d}{d_o} = 1.038, \text{ hence } d = 1.038 \times 5.947 = 6.15 \text{ cm.}$$

$$\Sigma k = 8\frac{d}{d_o} = 1.092, \text{ hence } d = 1.092 \times 5.947 = 6.84 \text{ cm.}$$

$$\Sigma k = 16.3\frac{d}{d_o} = 1.172, \text{ hence } d = 1.172 \times 5.947 = 6.96 \text{ cm.}$$

A similar example is worked out for Q = 3400 kg. per hr., which does not materially differ from the preceding one. (*Zeitschrift für Dampfkessel und Maschinenbetrieb*, vol. 44, no. 26, July 1, 1921, pp. 201–204, 2 figs., *pa*)

Short Abstracts of the Month

AERONAUTICS

German War Aeronautical Motors

Evolution of German Aeronautical Motors During the War, Capt. Harlaut. The evolution of the aeronautical motor in Germany was governed by the following three facts: first, unanimous opinion of German engineers that aeronautical motors should have 6 cylinders, arranged in a straight line and water-cooled; second, the appearance in 1916 of the Hispano-Suiza motor; and third, the search from 1917 for a motor of constant power, and simultaneously the study of variable-speed propellers.

Because of the shortage of raw materials the early German motors were inferior to motors of the Allies from the point of view of weight per horsepower and maintenance, which led the German administration to prescribe very stringent acceptance conditions for their motors. Not being able to secure the advantage of superior lightness, they sought to compensate for it by increase of power.

In 1916 a special effort was made to increase the output per unit, Daimler trying to achieve it by the increase in the number of cylinders from 6 to 8 in straight line, and Benz by an increase in piston displacement. A demand for still greater power output was brought about in 1917 by the need of large motors for bombing planes, the power output per unit reaching as high as 260 hp.

By the winter of 1917–18 pursuit planes, such as the Spad, brought about the demand for still more powerful engines. The Benz-4 type was too heavy, but the experience with the Maybach 260-hp. motor showed that a very material improvement in the power of a motor might be brought out by an increase in piston displacement and of compression obtained at a cost of a slight increase in weight. The Bavarian Motor Works were given the task of redesigning the 160-hp. Mercedes (D-III), which led to the development of the B.M.W.-IIIa, 185-hp. motor.

The demand of bombing planes for motors of 500 to 600 hp. led to many unsuccessful attempts on the part of the German designers. The B.M.W. built a 6-cyl., 180 × 180-mm. (7.2 × 7.2 in.) which at 1300 r.p.m. developed from 300 to 400 hp. The power proved to be insufficient and overheating developed.

Benz tried the use of cylinders 225 by 300 mm. (9 × 12 in.) with six valves and four spark plugs per cylinder and pressure oil cooling of cast-iron pistons. At 1400 r.p.m. the engine developed 623 hp., but the crankcase broke on account of vibration and the cooling of the pistons proved to be unsatisfactory.

Maybach succeeded in increasing materially the power output by simply adding a flywheel weighing about 50 kg. (110 lb.), using the same 6-cyl. engine with four valves per cylinder and a compression ratio of 6.07. Notwithstanding the presence of the flywheel, however, the vibration proved to be such as to endanger the crankcase.

Daimler succeeded in developing the 260-hp. Mercedes type into a motor giving 650 hp. at 1250 r.p.m. and weighing only 1050 kg. (about 2300 lb.), but the vibrations were such as to cause fracture of the crankcase.

On the whole, therefore, the German attempts to develop a high-power aeronautical motor prior to the Armistice proved to be a failure. Not being able to do so in an engine of a small number of cylinders, they tried to increase the number of cylinders, Daimler employing as many as 18. The only motors of this character were the Benz 500-hp. Bz-VI and superinduced Bz-VIv, the first developing 500 hp. and the other up to 675 hp. at peak load. It was the only high-powered type used by the Germans and consisted practically of two of the standard Benz motors V-coupled.

The appearance of the Hispano-Suiza motor produced a tremendous impression on German engineers by showing them the value of the V-type motors. Out of a number of types developed along the same lines as the Hispano-Suiza only the Benz and the Körting were accepted by the military authorities. Benz built an 8-cyl. motor giving 214 hp. at 719 revolutions, or 200 hp. at 1400 revolutions, no gear reduction being used at this latter speed.

The Körting motor is remarkable for its short length and compactness. It is also an 8-cylinder V-type, 110-mm. bore, 140-mm. stroke, with four valves per cylinder, running at twice the speed of the propeller, and developing 183.5 hp. at 2110 r.p.m.

On the whole, however, the development of the V-type motor was not of material assistance in the war. By the time it was completed (beginning of 1918) the motors no longer answered the demands of the day and a further step was made by Körting in developing a 12-cyl. motor and by Benz in the Bz-V, 145-mm. bore 160-mm. stroke, developing at 1500 r.p.m. as high as 450 hp. In the general scheme, the motor did not differ from the other Benz motors, namely, individual steel cylinders with cast-iron liners and sheet-iron water jackets autogenously welded, aluminum pistons, double magneto ignition and separate carburetors for each group of three cylinders.

It is notable, however, that many refinements were made permitting the reduction of weight and greater compactness of design. The four carburetors and the dynamo are placed inside of the V. A single camshaft is used, with three valves per cylinder, and a triple gear-driven lubrication pump and a gear reduction along the lines similar to those used by the Rolls-Royce concern but differing in some of the minor details. (First installment of a series, *L'Aeronautique*, vol. 3, no. 27, Aug. 1921, pp. 310–315, 10 figs., *d*)

AIR ENGINEERING

Experiments on the Effects of Extremely High Pressures, T. W. Bridgman. Data of an investigation in a field of which comparatively little is known, but in which the author has been working for several years. The author states that he worked with pressures as high as 20,000 atmos. or about 300,000 lb. per sq. in. (roughly ten times as high as the explosion pressure in a large gun).

Such tremendous pressures are obtained by the use of a patented device which is said to be absolutely free of leak as long as the steel containing vessel is itself strong enough to withstand it.

In the course of this work the author found that the engineering theories of the strength of vessels do not hold good at these high pressures. A cylinder will stand much more pressure than it is ordinarily credited with, and will also stretch a good deal more than the ordinary tensile test would suggest. When it breaks the crack starts on the outside where the stretch and stress are presumably least, and travels toward the inside where they are expected to be greatest.

Pressure was produced by a small piston driven by a hydraulic press operated by a hand pump. This pressure was transmitted through a connecting pipe drilled out of a solid bar. A modification of the dead-weight gage was used and as a secondary standard, one based on the change produced by pressure in the electrical resistance of a metal (manganin alloy).

In general it was found it is not possible to force ordinary liquid into the pores of a metal, even at the above high pressures. However, hydrogen compressed to a pressure of 10,000 atmos. will eat its way through a massive steel container and blow out. Compressed air apparently behaves in the same way, although at a slower rate, while mercury behaves much like hydrogen and can be forced through massive steel walls by about 60,000 atmos. pressure.

Under high pressure liquids were found to be comparatively highly compressible. By 12,000 atmos., water may be compressed to 20 per cent less than its normal volume, and even metals showed appreciable compressions.

Under sufficient pressure a liquid can be forced to freeze at temperatures substantially higher than its freezing temperature.

instead of floating in water. Water at 180 deg. fahr. may be forced to freeze to this kind of ice by the application of about 20,000 atmos.

At 12,000 atmos. and 200 deg. cent. (923 deg. fahr.) phosphorus assumes a black form like graphite in appearance, loses its combustibility, becomes a conductor of electricity and is 50 per cent denser than yellow phosphorus. (*Compressed Air Magazine*, vol. 26, no. 9, Sept. 1921, pp. 10223–10225, 4 figs., *dA*)

BALLISTICS

The Study of Bomb Ballistics, H. L. Dryden. Description of recently developed methods for the study of ballistics of bombs launched from aircraft.

The early methods were rather crude; the more modern method is that in which the plane speed, altitude, and point of release of the bomb are determined by the use of two cameras obscura. In this method records are taken every second, and apparently reliable information is obtained regarding the trajectory of the bomb but not as to its oscillations or details of its behavior in the air. The method is used chiefly to secure approximate range data and probable dispersion due to all causes.

The second method for securing range data for bombs was worked out by Doctor Duff. A special bomb, with the source of light in the tail, was dropped at night and the part of the bomb was photographed by two cameras placed at the end of a measured base line and pointing at known angles to the horizon. From the trajectory of the cameras and the records on the plate the range may be computed.

Another method developed by Dr. F. C. Brown involves the study of bomb trajectories by means of moving pictures taken from the plane from which the bomb is dropped. If properly used, this method gives a great deal of information; for example, it permits the investigation of the oscillations of the bombs and likewise the behavior of the bombing plane. However, the method is difficult of application.

What promises to be an interesting method is the study of bomb ballistics by means of wind-tunnel measurement. Much valuable information has already been obtained in this way, and it is expected that ultimately it will be possible to predict, from wind-tunnel tests, the complete behavior of any proposed form of bomb. (*Army Ordnance*, vol. 2, no. 8, Sept.–Oct. 1921, pp. 83–85, 4 figs., *de*)

ELECTRICAL ENGINEERING

Probable Limits of Electric Generators and Superpower Plants for Germany, Prof. W. Reichel. Discussion of the problem of the most economical and the largest commercially possible sizes of electric generators for central stations. The economy of large units is generally recognized and an interesting discussion is devoted to the question as to the largest commercially possible sizes.

The most advisable speeds for various sizes are given as:

3000 r.p.m. for generators up to 25,000 kva.
1500 r.p.m. for generators up to 40,000 kva.
1000 r.p.m. for generators up to 60,000 kva.

As examples of large generators two units are cited of 60,000 kva. at 1000 r.p.m. installed during the war in Germany. The diameter of the rotor is 2.25 m. (7.40 ft.) so that the peripheral velocity at 1000 r.p.m. is about 118 m. (387.1 ft.) per sec. Such large dimensions required a very powerfully built axle and also a design in which the critical speed was higher than the operating speed. As a matter of fact, the axle weighs 36 metric tons (39.1 short tons).

The author distinctly states, however, that theoretically it is by no means impossible to go considerably beyond 60,000 kva. for such generators. In fact, he says that it has been established by calculation that generators may be built in sizes up to 160,000 kva., and the most serious obstacle in the way of accomplishing such constructions lies in the difficulty of transportation of such huge machines by railroad, necessitating their assembling and, in particular, winding at the place of installation—an operation not always attractive.

The use of such giant machines is suggested in a central station with six units, one being a standby. Such a plant would have a normal load of 400,000 kw. and a peak load of 500,000 kw., with a total output per year of, say, 2,000,000,000 kw-hr. Five such central stations would be sufficient to satisfy the entire demand for electric power in Germany.

For steam turbines to drive the 160,000-kva. generators the article suggests double units with steam admission in the middle, 16 to 17 atmos. pressure at the turbine inlet and 20 atmos. gage pressure on the boiler, with a steam temperature of 350 deg. cent. (662 deg. fahr.) at the turbine inlet valve.

In view of the great consumption of fuel and of water for condensation, it is obvious that such big plants should be located only near a large coal supply and also near a large river. Assuming coal delivered 300 days in the year, this would mean that 7500 tons per day would have to be received into the plant and be distributed either to the boiler rooms or to the bunkers.

The general conclusion to which the author comes is that at present the limit to the size of electrical generators is set mainly by the demand for power. (*Zeitschrift des Vereines deutscher Ingenieure*, vol. 65, no. 35, August 27, 1921, pp. 1911–1917, 22 figs., *g*)

ENGINEERING MATERIALS

Rust Prevention by Slushing, Haakon Styri. Investigation of rust formation and prevention by slushing; of interest also because the experiments were conducted by exposure tests in humidors, similar to the method adopted by the U. S. Bureau of Mines in Pittsburgh. It was believed that if material in process could be protected from rust, cleaning before slushing would become possible.

Preliminary experiments have shown it necessary to use an aqueous washing liquid for the elimination of salts on the surface and for protection against action of the atmosphere. To do this, tests were made with washing in an emulsion of soap and mineral oil; it was expected that the aqueous solution would dissolve the salts and emulsify fats and fatty acids on the surface of the steel, and the oil particles would form a protective coating when they adhered to the surface.

Tests were made with the solutions either cold or boiling, the latter having been found preferable from the point of view of results. (Paper before the 40th Meeting of the *American Electrochemical Society*, Sept. 29–Oct. 1, 1921, abstracted from advance copy, pp. 113–128, *e*)

FUELS AND FIRING

Liquid Fuels in Internal-Combustion Engines

The Economical Utilization of Liquid Fuel, Carl A. Norman. An extensive discussion of the supplies of liquid fuel as they affect America, and their utilization in steam and internal-combustion engines. The author is Director of the Engineering Experiment Station, Ohio State University. Only a brief abstract of some parts of the investigation can be given.

The author states that the fuel situation is rendered unnecessarily complicated by trying to keep various fuel distillates apart and that a much better policy might be to mix them all together under a common name of distilled motor fuel. He advises that there are rumors that the oil industry has actually agreed on such a mixture as a standard motor fuel a few years from now.

The use of kerosene in automotive engines has been practically achieved for certain conditions, but the author considers it fortunate that no very determined efforts to adapt passenger cars and trucks for operation on kerosene have been made, because if this had been done the time would come when kerosene would sell at exactly the same price as gasoline. Indeed, the price of kerosene is now advancing much more rapidly than that of gasoline.

Passage of a Gas through a Throttle Valve. The throttling of a gas produces no temperature drop. The end temperature of compression should be the same in a throttled as in an unthrottled engine. If knock is relieved by throttling, then knock is dependent on the pressure attained rather than on the temperature.

Cooling by the Charge. The evaporation of the charge is capable of producing a cooling effect amounting to 50 or 60 deg. fahr. if the evaporation is complete. This cooling effect is naturally reduced by the imperfect evaporation of present-day fuels. It may be masked by heat from the engine parts. Experiments on a truck and tractor engine show it to be of quite the magnitude computed when the air heating is at its maximum.

Evaporation Temperatures of Liquid-Fuel Mixtures. Moisture will not condense out of atmospheric air, even if the temperature of the air is much below the boiling point of water under atmospheric pressure.

The amount of vapor that air can absorb and keep evaporated depends upon temperature of the air, pressure of the vapor in the air and boiling point of the vapor under this pressure.

A method is given to determine the amount of petroleum fuel that can be kept evaporated in air at various temperatures. It is found that for perfect evaporation of present-day gasoline a mixture temperature of about 110 to 130 deg. fahr. is necessary, while for kerosene the temperature must be raised somewhat over 200 deg. fahr.

Effect of Charge Heating on Engine Output. Charge heating reduces the ratio of the absolute temperature after combustion to the absolute temperature before combustion, and hence reduces the pressure rise.

Heat Development in Combustion Engines. The purpose of this article is to investigate the heat development with various mixtures. The nature of the chemical reactions is first discussed, and then the heat derivable from each one of the reactions ascertained.

Efficiencies Attainable in Internal-Combustion Engines. The maximum amount of work producible by a chemical reaction may be greater or less than the heat of reaction. In the case of combustion processes, it is in most cases very nearly equal to the heat of reaction. By utilizing the reaction in electrochemical primary batteries, very high factors of utilization may be attained and have experimentally been attained. If the enormous expansion ratios common in steam turbines were possible in internal-combustion engines, then this class of engines might also, in theory, turn perhaps 75 per cent of the heat energy into power.

As such expansions are not manageable with present types of engines, even ideally perfect engines of this kind could attain only very much lower heat utilizations. What these ideal standards are with actual fuels and actual combustion processes has been investigated on the theoretical side by Tizard and Pye, among others, and on the practical side by Ricardo, among others. A sample calculation of such an ideal efficiency is given.

These efficiencies are much lower than the so-called "air-standard" efficiencies. In fact, the margin of possible improvement of present-day engines at their best, is less than one might expect. For this reason, the desirability of maintaining a receptive attitude toward possible new types of prime movers is emphasized. (Bulletin No. 19 of the *Engineering Experiment Station, Ohio State University*, July 1921, 206 pp., illustr., *geA*)

Power Gas From Sewage

Power Gas from Sewage, J. D. Watson. Recent experiments at Birmingham, England, have shown that it is practical and economical to drive a suction-gas engine from gas derived from sewage sludge. Fig. 1 shows diagrammatically the experimental installation used at Birmingham. The pump installation comprises a 34-hp. horizontal gas engine of the ordinary suction type, a 5-in. diameter centrifugal sludge pump, and other parts as shown in the drawing. The gas holder indicated at *E* has not yet, however, been erected.

The engine is capable of giving 34 b.hp. at 250 r.p.m., with town gas having a heat value of 500 to 550 B.t.u. per cu. ft. In tests made with sewage gas from $27^1/_2$ to 32 hp. maximum have been obtained. The principal constituents of sewage gas are methane, hydrogen, nitrogen and carbon dioxide, the percentage of marsh gas varying in the different places investigated in accordance with local conditions.

The volume of wet sludge dealt with at Birmingham is estimated at not less than 400,000 tons per year. The author estimates that from this sludge 9000 tons of dry solid matter are available to produce 320,000,000 cu. ft. of gas equal to 16,000,000 hp-hr., an equivalent of 4400 hp. per day of 10 hr. (Paper read before Section G of the British Association at Edinburgh, Sept. 14, 1921, abstracted through *Engineering*, vol. 112, no. 2908, Sept. 23, 1921, p. 456, 2 figs., *dA*)

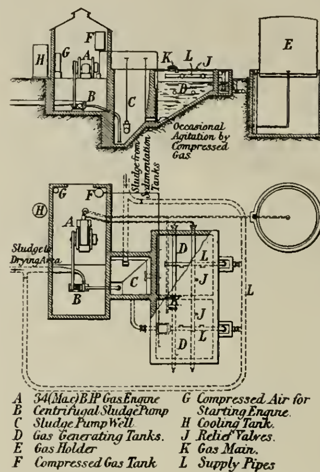

Fig. 1 Experimental Installation at Cole Hall, Birmingham, to Utilize Power Gas from Sewage

HYDRAULIC ENGINEERING

Speed Regulation of Hydraulic Turbines, John S. Carpenter. Discussion of principles and methods of calculation involved in the design of hydraulic-turbine governors. The article is not suitable for abstracting, but is of considerable interest because it gives the calculations necessary to understand the design of governors, omitting, however, the part of the calculations employing higher analysis. Therefore, to those equipped with only an elementary knowledge of mathematics, it provides a suitable basis of presenting the questions involved in water-turbine governor design. (*Power Plant Engineering*, vol. 25, no. 19, Oct. 1, 1921, pp. 947–950, 1 fig., *gp*)

INTERNAL-COMBUSTION ENGINEERING (See also Aeronautics; Fuels; Marine Engineering)

Distribution of Frictional Losses in Internal-Combustion Engines, E. P. Taylor. Data of tests carried out at the P. N. Russell School of Engineering in Australia. The tests were carried out by using the so-called retardation method on a 6-hp. Victor oil engine, 6-in. bore and 8-in. stroke.

The engine was of the vertical enclosed crankcase type, with plain bush bearings lubricated by the splash in the crankcase running through holes in the upper part of the bearings, the bearings being flooded by hand feeding. The engine was driven by a belt from an electric motor, a record being kept of the temperatures of the main bearings and cylinder.

In addition, two other engines were used, a National gas engine and a Crossley. The former was of the horizontal 4-stroke cycle, 11-in. bore and 19-in, stroke, only the temperature of the cylinder was observed, and the speed was attained by driving under gas in the ordinary way. The Crossley gas engine, was a 30-hp., $9^1/_2$-in. bore and 18-in. stroke. The main tests were carried out on the Victor engine.

A detailed account is given of the retardation factors for various elements of the engine. The main data are assembled in Tables 1 and 2. From these tables it would appear that even with different types of engines there is such a general agreement in the percentage of friction allotted to each part that a general table showing

justified. Limitations of the retardation method of testing are indicated. (Paper published in the Journal of Proceedings of the Royal Society of New South Wales, abstracted through *Gas and Oil Power*, vol. 16, no. 192, Sept. 1, 1921, pp. 190–192, *et*)

TABLE 1 COMPARISON OF DISTRIBUTION OF FRICTION IN VARIOUS INTERNAL-COMBUSTION ENGINES

Part of Engine	National 40-hp.	Crossley 30-hp.	Victor 6-hp.
Main bearings	15 per cent	16 per cent	11.5 per cent
Layshaft and valve gear	2	4	1.5

Still Oil Engine for Marine Propulsion. Description of the Still oil engine (see Mechanical Engineering, p. 627, 1919) constructed by the Scotts Shipbuilding and Engineering Co., Greenock, for use on shipboard, and tested by a deputation of engineers representing the French government and commercial interests.

The engine is said to be the largest of the type so far constructed and is of the low-speed marine type designed for merchant service. The Still engine is a combination of oil and steam engines. The main source of power is oil, consumed within a cylinder on the down stroke. The steam is generated in the cylinder jacket and forms a supplementary source of power used on the up stroke.

The present engine has a stroke of 36 in. and bore of 22 in. Efficiencies obtained in trials in May 1921 were: At full load, combustion i.hp. efficiency, 44.8 per cent; engine b.hp. efficiency, 39.4, net b.hp. efficiency, 37.7. At half load the respective efficiencies were 46.2, 38.5 and 35.8; at quarter load 46.1, 34 and 30.0. The total oil consumption per i.hp-hr. was found to be lower than in a good Diesel engine; at full load it was 0.360 lb. per b.hp-hr., at an overload of 11 per cent, 0.398 lb. per b.hp-hr. and at quarter load as high as 0.47 lb. (*Engineering*, vol. 112, no. 2905, Sept. 2, 1921, pp. 344–345, 2 figs., *eA*)

Piston-Temperature Measurements in Oil Engines

Measurements of Temperature in the Pistons of Oil Engines, Dr. Eng. W. Riehm. Description of methods developed for direct measurement of temperature of non-cooled pistons of Diesel engines under various operating conditions, and discussion

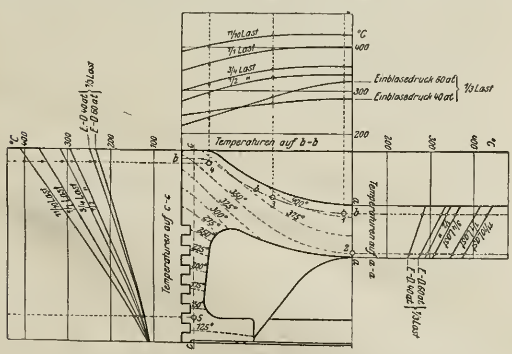

Fig. 2 Temperatures in Pston Body A at Various Loads
(*Last*, load; *temperaturen auf*, temperatures along.)

of temperature distribution in pistons of various designs. The tests were made on an experimental unit developing 70 hp. at 165 r.p.m. and working with tar oil to which a lighter oil is added at small loads. The thermoelements consisted of base metals (iron-constantan and copper-constantan), and a special two-part piston was built to provide a convenient location for the thermocouples.

air-injection pressures. In the upper part of the cylinder B the temperature lines are practically concentric to the axis of the piston, and the entire distribution in the body approaches that of a cylinder heated from the inside.

On the other hand, the piston body proper A shows a greater temperature difference between the center part and the rim and more approaches in character more the case of a plate heated in the middle. Also the maximum temperatures in the middle of the body are a good deal higher. These differences in temperature distribution are ascribed primarily to the fact that the heat is not transmitted throughout the body in a uniform manner, but is given mainly to the region where the fuel jet strikes with the higher temperature and greater velocity. Fig. 3 is of interest as showing the influence of air-injection pressure on the heat transmission and temperature distribution in the piston body.

The other parts of this interesting article cannot be abstracted owing to lack of space. (*Zeitschrift des Vereines deutscher Ingenieure*, vol. 65, no. 35, Aug. 27, 1921, pp. 923–925, 7 figs., *e*)

MACHINE DESIGN AND PARTS

Pipe Bends

Relative Values of Types of Bends and How They May Be Most Effectively Installed. In this article it is claimed that the assumption that the expansion U-bend is only twice as effective as a plain U-bend, is not correct. The derivation of an expression for the expansive value of an expansion U-bend is given.

The various kinds of bends are shown in Figs. 4, 5 and 6. In the bend in Fig. 5, the deflection at P is obtained in two steps—first, by considering the deflection in the length XY, assuming the outer leg XP to be rigid, and then considering the deflection in XP under the assumption that the portion XY is rigid.

It can be demonstrated by calculus that the horizontal component of the movement at P due to flexure of the bend in the portion XY is

$$\frac{a^3P}{EI}\left(\frac{3\pi}{4}+2\right) \qquad [1]$$

and that the corresponding movement at P due to flexure in the portion XP is

$$\frac{a^3P}{EI}\left(\frac{3\pi}{4}-2\right) \qquad [2]$$

Adding [1] and [2] and multiplying by 2 for both halves of the bend, we have $D = 3\pi a^3P \div EI$. But for the condition of maximum fiber stress, $P = SI \div ad$. Substituting this value of P, we get

$$D = \frac{3\pi a^3S}{Ed} \qquad [3]$$

which represents the total deflection of an expansion U-bend in one direction from the normal or unstrained position. The deflection of a plain U-bend may be found in the same manner to be

$$D = \frac{\pi a^2 S}{Ed} \quad \ldots\ldots\ldots\ldots [4]$$

which represents the deflection of a plain U-bend one way from the normal or unstrained position. It is thus seen that if the effect of the short tangents necessary at the ends of pipe bends for installing the flanges is neglected, the expansive value of an expansion U-bend, as shown in Fig. 4, is three times that of a

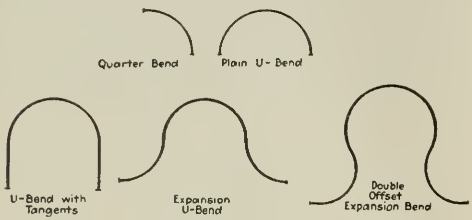

Fig. 4

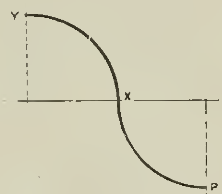

Fig. 5

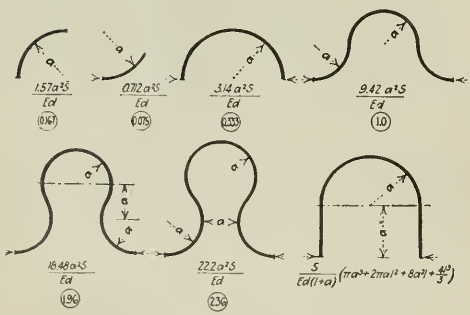

Fig. 6

Figs. 4, 5 and 6 Pipe Bends for Expansion in Pipe Line

plain U-bend with the same radius, using the same size of pipe. The expansive value is seen to be independent of the thickness of the walls of the pipe, an extra heavy bend having the same capacity as a bend made from standard-weight pipe. This is true, however, only in case the effect of the internal steam pressure is neglected. For bends composed entirely of circular arcs the allowable deflection is proportional to the square of the radius for a given maximum fiber stress, where

- D = expansive value of the bend either way from the normal or unstrained position
- a = mean radius of bend in inches
- d = outside diameter of pipe in inches
- M = bending moment
- E = modulus of elasticity of the material
- I = moment of inertia of a cross-section of the pipe
- P = thrust in lb.
- S = maximum fiber stress, lb. per sq. in.

The expansive value of a quarter bend depends upon the way it is installed in the line. The formulas for different bends are given in Fig. 6, the expansion being one way from the normal or unstrained position. From Fig. 7 the allowable expansion for any of the bends shown can be obtained by using the relative value factors shown in Fig. 6. (*Power*, vol. 53, no. 19, May 10, 1921, pp. 742–743, 4 figs., *p*)

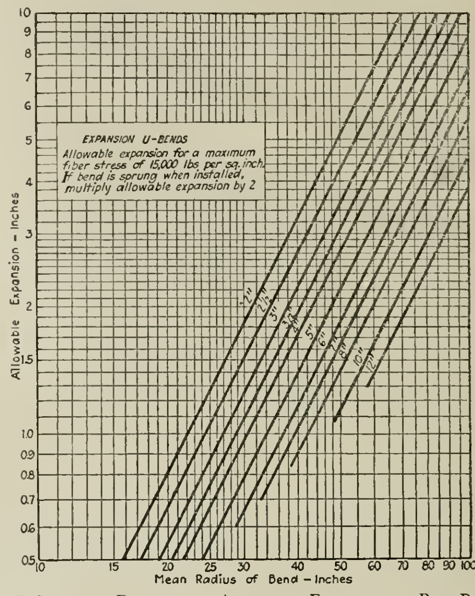

Fig. 7 Chart for Determining Allowable Expansion in Pipe Bends

MARINE ENGINEERING (See also Internal-Combustion Engines)

Turbo-Electric Propulsion. Rumors persist in British engineering circles that one of the four new battle cruisers of this year's naval program is to be fitted with turbo-electric propulsion. An editorial points out that British Admiralty engineers have very little actual experience on the subject beyond that gathered from foreign sources—in particular, from America.

Concerning this latter, it is stated that the U. S. Navy Department exhibited extraordinary boldness in passing directly from the New Mexico type (24,000 kw.) to battleships of 60,000 and cruisers of 180,000 shaft hp. The latter are to be propelled by four shafts, and the application of motors of 45,000 hp. to each will be a noteworthy feat.

The editorial does not recognize the validity of claims made for electric driving. Instead it claims that with mechanical gearing there is a greater flexibility of speed than with electric transmission, as the latter must rotate at revolutions which suit the number of cycles employed while the former may run at any odd number.

Certain alleged disadvantages of the electric system are also pointed out, such as lower economy at all except very low powers, considerably greater weight and more complexity by the full extent of the system of electrical control, the steam element remaining practically as before. It is also stated that experience of small merchant vessels with turbo-electric propulsion has been anything but satisfactory in some cases, though a number of vessels in the United States are to be fitted with it. (Editorial in *The Engineer*, vol. 132, no. 3428, Sept. 9, 1921, p. 267, *g*)

British Motor Tanker and Its Engines

The Motor Tanker "Conde de Churruca." Description of a twin-screw oil tanker recently launched at the works of Sir W. G. Armstrong, Whitworth and Company. It is propelled by

recent type of design and also being the largest engines of this type which have up to the present been fitted in a British mercantile vessel.

The deck machinery, consisting of the anchor windlass, winches, and derricks, is all steam-driven, the steam being raised in an oil-fired donkey boiler which also provides steam for the heating coils in the cargo and fuel tanks.

The engines each develop 1250 b hp. at 100 r.p.m. in four cylinders, 600 mm. bore and 900 mm. stroke. They are equipped with the Sulzer rotary sleeve valve (Fig. 8) which controls the admission of scavenge air to the cylinder. The correct position of this valve is determined for ahead and astern by a simple loose eccentric worked from the operating gear.

The starting and reversing mechanisms are so interlocked that no false start can be made. During the trials it was shown that each engine could be started and stopped twelve times consecutively without replenishing the starting receivers, of which there are eight, each of 800 liters capacity. In addition to the high-pressure receivers, there is a low-pressure receiver supplied through a reducing valve. This receiver provides air service for the service motors for the operating gear and the turning gear, and also for the air-driven lubricating-oil priming pump and the whistle.

The piston is cooled by a spray, sea water being used as the cooling medium. During the war an experiment was made to test the effect of heat stress on the delicate parts of the engine. The test engine was overloaded till the exhaust pipe was heated to redness and collapsed. When the engine was opened up the piston rings were intact and the lubrication was unimpaired, owing to the efficiency of the cooling system. The piston itself is made in two sections. The crown is only about 44 mm. thick, and is supported by five buttresses of special shape which allow the piston to take up its own position when the heat stresses come on. The piston

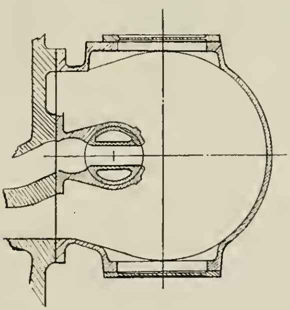

Fig. 8 Sulzer Rotary Scavenge Valve

rod is so joined to the body that the piston is free to expand radially, and it is claimed that sticking is entirely eliminated.

All control mechanism is grouped on the top platform in full sight of the valve-gear and fuel-pump mechanism. However, this is optional and the makers are also prepared to fit auxiliary control on the lower platform. The starting valve is operated by a mechanical device, so constructed that it can be readily removed and examined. This makes it possible for the engineer to assure himself that the maneuvering gear is in good working order.

Of the auxiliaries attention is called to the Hele-Shaw electric steering gear, and the combined compressor and generator built by Sulzer Brothers to be used for emergency purposes. The latter consists of a two-stage air compressor delivering air at 1200 lb. per sq. in. driven by a 12-hp. hand-started hot-bulb engine, which is also coupled to an 8-kw. 110-volt emergency generator.

The two engines, with flywheels, pumps and all fittings, weigh about 330 tons. (*The Engineer*, vol. 132, no. 3429, Sept. 16, 1921, pp. 297–301, illustrated, *d*)

MECHANICS (See Internal-Combustion Engineering)

The Alignment Chart, C. W. Crockett. Presentation of a basis for the construction of alignment charts and a method interpreting charts. Alignment charts lend themselves to the graphical representation of mathematical relations of many kinds and may save a great deal of calculation work.

The article is of a strictly mathematical character and not suitable for abstracting. As an example, a chart is given by which one may determine the diameter of the wire and the mean diameter of the coil of a helical spring formed of round steel wire if the amount of compression and extension, the maximum load, and the solid height are given, and also determine the extreme fiber stress under that load. (*Automotive Industries*, vol. 45, no. 13, Sept. 29, 1921, pp. 614–618, 5 figs., *pg*)

MOTOR-CAR ENGINEERING

Brotherhood 5-Ton Steam Wagon. Description of a steam truck of British manufacture which is unusual in some respects. The boiler is of a type which has about double the heating surface usual in steam wagons. It is of a type, too, in which the smokebox doors at each end are utilized as chambers for the exhaust steam, which thence escapes through small nozzles along the upper tubes of the central combustion chamber at the base of the chimney. In the present design each smokebox door has six exhaust nozzles

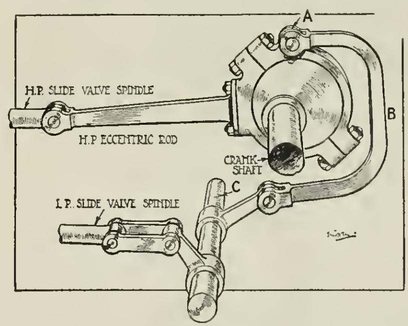

Fig. 9 Valve Gear of the Steam Engine in the Brotherhood Steam Wagon

discharging through a single row of large tubes. Incidentally, each exhaust pipe is formed with a trap for condensation. By disposing of the exhaust steam by this method, it is obvious that a steadier and gentler draft is possible. Consequently, the type affords an easy steamer, requires little or no forcing, and pulls its fire about but little. The water level is less affected on steep gradients than in any other design. The fusible plug can be fixed 8 in. to 9 in. below the water line, and so the risk of burning it out is very remote.

The engine motion is such that the D-slide valves of both high- and low-pressure cylinders in both forward and reverse directions are operated off a single eccentric. The principle of this motion is as follows: The cranks of the two cylinders are at right angles to each other. The eccentric works the high-pressure valve direct and at a point 90 deg. further round (to correspond with the position of the low-pressure crank), the eccentric strap carries a lug A, whence a link B transmits this motion to a rocker shaft C, off which the low-pressure valve is actuated. The whole arrangement is best seen in Fig. 9. Incidentally, this is the only undertype steam wagon employing a compound engine. (*Motor Transport*, vol. 33, no. 863, Sept. 12, 1921, pp. 277–279, 9 figs., *d*)

MUNITIONS (See Ballistics)

POWER-PLANT ENGINEERING (See also Electrical Engineering; Machine Design and Parts)

Electrically Operated Speed Governor for Traveling Grates

Speed Governor for Traveling Grates, Generlich. Description of a device built by Bosselmann, of Berlin, Germany,

engineer (Fig. 10). In this the factor governing the speed of progression of the grate through an electrical transmission is the temperature of the cooling water on the wiper. The principle of this device is that with a constant supply of cooling water, its temperature will be the higher the nearer the flame part on the grate approaches the wiper, which means the more poorly the coal is burned.

Referring to Fig. 11, the wiper consists of an iron plate 10 mm. (0.4 in.) thick and a water-cooled body made up of a T- and L-iron shapes properly bent and welded together.

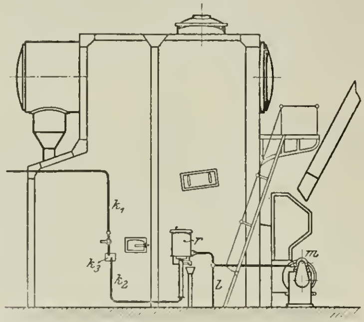

Fig. 10 Traveling Grate-Speed Governor
(k_1 cooling water inlet; k_2 cooling water outlet; l lead to motor starter; m motor; r speed governor.)

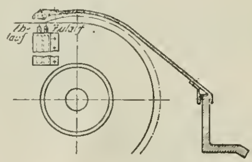

Fig. 11 Wiper with Water-Cooled Body
(*Zulauf*, water inlet; *Ablauf*, water outlet.)

The cooling water flows first to the chamber at the rear and then through that located toward the grate. The thin walls transmit well the heat to the cooling water, the temperature of which may vary between 40 and 70 deg. cent. (104 to 158 deg. fahr.).

In the unit tested by the author the wipers on a double grate have been in use for four months without showing any material signs of wear or requiring any repairs.

The most important part of the governor itself is the Samson expansion device, Fig. 12. This consists of a tube *a* filled with glycerine, in which is located a metal hose *b* and a piston with piston rod *c*. The governor is inserted into the second tube *d*, through which passes the wiper cooling water. The heat from the cooling water is transmitted to the glycerine. To make the piston stroke as great as possible, the metal hose *b* is given the length of 1 m. (39.37 in.) and its elongation per deg. cent. of rise of temperature is 1 mm. (0.02 in. per deg. fahr). To the piston rod *c* is connected the bridge *e* carrying 12 vessels *f* filled with mercury and arranged so that into these vessels may dip corresponding graduated contacts *g*.

These contacts in their turn are so arranged as to short-circuit in 13 stages the resistance inserted in series with the armature of the motor driving the grate, the entire resistance being short-circuited when all the contacts dip into the mercury, which happens when the cooling water is cold. On the other hand, when all the contacts are out of the mercury, which happens when the cooling-water temperature is high, then the entire resistance is in series. In this way the cooling-water temperature is enabled to govern the voltage on, and hence the rotation of, the motor within wide limits. To prevent sparking at the withdrawal of the contacts from the mercury and also the evaporation of the mercury, a thin layer of paraffin is spread over the surface of the mercury.

The author of the present article carried out some tests on this device in the boiler room of the Osram Co. in Berlin, and found that the voltage and speed of the motor were quite closely governed by the temperature of the water, being, for example, 220 and 1500 respectively at water temperature of 47 deg. cent., 70 and 480 at 67 deg. cent., etc.

The installation apparently requires only one additional valve in the water-cooling system, this valve having a permanent setting for each plant and each given set of operating conditions. (*Zeitschrift des Vereines deutscher Ingenieure*, vol. 65, no. 36, Sept. 3, 1921, pp. 943–944, 5 figs., *d*)

PRIME MOVERS (See Steam Engineering)

STEAM ENGINEERING (See also Internal-Combustion Engines; Motor-Car Engineering)

A Closed-Cycle Ammonia Motor

Closed-Cycle Ammonia Motor, Prof. E. Garuffa. Many attempts have been made to produce a "steam" engine employing a liquid vaporizing at a lower temperature than water, and there are numerous patents on such engines, none of which, however, have reached a stage of commercial development.

Of such engines the ammonia motor originally developed by an Italian engineer, B. Caruso, possesses certain features of interest. In this engine an attempt is made to utilize to a very high degree the latent heat of the exhaust vapor, which has never been successfully accomplished in steam engines. The thermal properties of ammonia are claimed to be such as to permit this utilization of latent heat to a greater extent than is possible with water.

The closed cycle operates essentially as follows: In the first place, there is a generator of saturated ammonia vapor doing work in a proper motor (e.g., a turbine) and constantly fed from another generator connected to it. In this second generator the exhaust vapor from the turbine gives up its heat to the liquid, and being condensed to a liquid state goes into an automatic feeder which delivers it to this second generator. Theoretically, under this cycle the only heat that has to be supplied to the ammonia in order to maintain the cycle is the heat corresponding to the work done and the heat necessary to compensate for losses—in particular, those which are not recuperated either before or after condensation. While at the same pressure, which is the maximum pressure of the cycle, the two generators which constitute the fundamental

difference in temperature being the temperature head across the turbine.

Fig. 13 illustrates the manner of actually effecting this cycle. A is a receiver or really a vapor generator heated by some fuel; M is the turbine or other kind of motor which receives the vapor from the ammonia generator after it has passed through the superheater S_A, the purpose of which is to utilize the heat in the exhaust from the furnace in the generator A. At B is a tank of liquid ammonia acting as a surface condenser; into it is immersed the coil S receiving the exhaust vapor from the turbine and condensing it. The condensate collects in the receiver C, whence it is conveyed by the pump P' to E, which, in its turn, constitutes an automatic feature of the condenser B, the latter acting as the second vapor generator.

The respective positions of the two units, A and B, (which, as has been stated above, act as two vapor generators at different temperatures) are such that they act as two communicating vessels (by pipe P) in such a manner that with equal pressures the levels of the liquid are the same.

Further, between the tank B and the dome D is inserted a special diaphragm d, and between the tank B and generator A another diaphragm R. These diaphragms permit the establishment of a uniform pressure throughout D, B and A, this being the maximum pressure of the cycle, at the same time maintaining between A and D and D and B the temperature head necessary for the motor to function.

The vapor which collects in D from surface evaporation of the

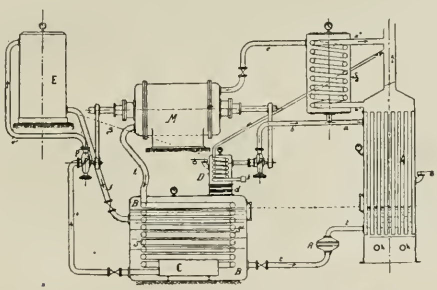

Fig. 13 Caruso Closed-Cycle Ammonia Motor

liquid in B is in a state of saturation due to its being in contact with the liquid and at a fixed temperature which may vary between 60 and 100 deg. cent. in accordance with the existing pressure. It is conveyed by the pump E as saturated vapor, into the generator A and from there, together with the vapor generated therein, is sent on its way first to the superheater S_A and eventually to the turbine M.

The purpose of the dome D is to maintain the liquid in B at a constant temperature, preventing the liquefaction of saturated vapor contained therein. To do this the dome is provided with a heating device which may or may not be connected with the furnace in A, and the heat coming therefrom helps to maintain the saturated vapor at a temperature of saturation corresponding to the maximum pressure of the cycle, 24 atmos. for 60 deg. and 60 atmos. for 100 deg. cent.

It is claimed that the efficiency of such a system is quite high. The heat content of a kilogram of superheated vapor Q is the sum of the heat content q of the saturated vapor and the superheat in the vapor, the latter being

$$q_1 = c_p\ (t_{\text{sup}} - t_{\text{sat}})$$

and hence the theoretical quantity G of steam per horsepower-hour in kilograms is

$$G = \frac{632}{Q} = \frac{632}{q + c_p\ (t_{\text{sup}} - t_{\text{sat}})}$$

(t_{sup} = temperature superheated vapor; t_{sat} = temperature saturated vapor). The actual quantity will be considerably greater, imperfect efficiencies of these units. Assuming that the heat losses are 10 per cent, efficiency of generator is 75 per cent, efficiency of turbine 70 per cent and efficiency of condenser 85 per cent, we get a total efficiency of 40 per cent and a consumption equal to 2.5 Q.

No statement is made as to whether any such engine has ever been built, and, if it has, what were the actual results of tests on it.

In his work on the ammonia motor Caruso worked out experimentally the following tables of physical quantities of ammonia.

TABLE 3 PRESSURE IN AMMONIA VAPOR AS FUNCTION OF TEMPERATURE

Temperature deg. cent.	Atmos.	Temperature deg. cent.	Atmos.	Temperature deg. cent.	Atmos.

CLASSIFICATION OF ARTICLES

Articles appearing in the Survey are classified as c comparative; d descriptive; e experimental; g general; h historical; m mathematical; p practical; s statistical; t theoretical. Articles of especial merit are rated A by the reviewer. Opinions expressed are those of the reviewer, not of the Society.

Corncobs and Their Uses

Only a few years ago the farmers in the corn belt of the United States considered corncobs as useless and undesirable refuse. They used them for fuel, but only when wood or coal was scarce.

Recently many important uses have been found for the corncob, which is no longer allowed to go to waste. Cellulose, which is the principal component of the corncob, is employed in the manufacture of various explosives.

From corncob pulp certain grades of paper may be made, and a valuable substance, furfural, may be obtained which is used in the manufacture of certain adhesives and forms the basis of a beautiful green dyestuff for silk. It is also an important reagent in the chemical laboratory. (*Steam*, vol. 28, no. 4, October 1921, p. 97.)

ENGINEERING RESEARCH

A Department Conducted by the Research Committee of the A.S.M.E.

A—Research Results

The purpose of this section of Engineering Research is to give the origin of research information which has been completed, to give a résumé of research results with formulas or curves where such may be readily given, and to report results of non-extensive researches which, in the opinion of the investigators, do not warrant a paper.

Apparatus and Instruments A9-21. Ring Gage Measurements. The Bureau of Standards is using three balls of the same diameter at 120 deg. apart with a fourth ball resting on them for the purpose of measuring ring gages. A method of governing contact pressure on the precision balls is being devised. Bureau of Standards, Washington, D. C. Address S. W. Stratton, Director.

Cement and Other Building Materials A12-21. Colorless Waterproofing. A preliminary report is being issued on the results of six months' exposure to weather of materials treated with 19 different waterproofing compounds showiug also the appearance when applied to light-colored stones. Bureau of Standards, Washington, D. C. Address S. W. Stratton, Director.

Cement and Other Building Materials A13-21. Foreign Specifications for Portland Cement. A chart 16 x 22 in. has been issued by the Bureau of Standards showing the principal physical and chemical requirements of portland cement as required by specifications of various countries. Bureau of Standards, Washington, D. C. Address S. W. Stratton, Director.

Fire Prevention A1-21. Report 2262 by A. C. Fieldner and S. H. Katz to the Bureau of Mines is on the Gases Produced by the Use of Carbon Tetrachloride and Foamite Fire Extinguishers in Mines. These extinguishers were obtained in the open market. The fluid in one consisted mainly of carbon tetrachloride and small quantities of other substances to prevent freezing. The foamite extinguishers contain a solution of aluminum sulphate in a central cylindrical tube and a sodium carbonate liquor solution in the annular space around the tube. When the two liquids mix CO_2 is produced and this throws a foamy liquid stream through a nozzle for 30 or 40 ft. The tests were made in an experimental mine belonging to the Bureau.

A wood fire was kindled and after this was freely burning an attempt was made to extinguish it, six men with extinguishers being ready for this work. Extinguishers were used one after another until the fire was put out. Samples of gas were taken into vacuum tubes at different distances from the fire. The results are given in the table below:

Distance from fire	Phosgene, parts per million	Hydrogen chloride, p.p.m.	Chlorine, p.p.m.	Carbon dioxide, per cent	Oxygen, per cent
5	30	180	0	0.39	20.52
25	..	150	0	0.43	20.47
45	90	...	0	0.53	20.37
75	20	250	0	3.05	17.80

Carbon Monoxide, per cent	Methane, per cent	Nitrogen, per cent
0.18	0.01	78.90
0.16	0.03	78.91
0.15	0.03	78.92
0.31	0.01	78.83

The foamite tests produce no dangerons gases although sufficient carbon monoxide was present to cause severe headache and nausea. The tetrachloride produced in addition to the tetrachloride vapor hydrochloric acid of from 150 to 255 parts per million and phosgene from 20 to 90 parts per million. Military authorities consider 25 parts per million of phosgene sufficient to produce death in 30 minutes. Hence care must be taken in using the tetrachloride extinguishers in underground fire fighting. They are not used for extinguishing fires in and around electrical equipment because the tetrachloride is a non-conductor of electricity. In small closed rooms it is dangerons to use this extinguisher. Bureau of Mines, Washington, D. C. Address H. Foster Bain, Director.

Fuels, Gas, Tar and Coke A15-21. Shale Oil. Report No. 2254 on the Nature of Shale Oil Obtained from Assay Retort and Report No. 2256 on the Oil-Shale Industry deal with data regarding oil shale particularly from the Rocky Mountain District. Bureau of Mines, Washington, D. C. Address H. Foster Bain, Director.

Fuels, Gas, Tar and Coke A1-21. Steaming in Vertical Gas Retorts. The first section of the Fuel Research Board of Great Britain for the years 1920-21 has just been issued. This section is on Steaming in Vertical Gas Retorts. The heading scovered are as follows:

Program of tests
General description of plant
Conditions under which test were made
Test for determination of heat losses from setting
Description of coals used
Description of carbonizing tests

General Remarks:
- "Heat Equivalent" of the setting at the Fuel Research Station
- General observation on tests
- Thermal efficiency of carbonization
- Behavior of steam in the retorts
- Economic and practical limits of steaming
- Suggestions for consideration on practical points
- Application of graphs to any individual setting
- "Heat Equivalent" for any individual setting.

The report may be obtained at 1s.6d. from the Imperial House, Kingsway, London, WC2.

Gases, General A1-21. Pressure-Volume Deviation of Methane, Ethane, Propane and Carbon Dioxide at Elevated Pressures. G. A. Burroughs and G. W. Jones have worked on pressure-volume relations in a manner described in Technical Papers 131 and 158 of the Bureau of Mines. Methane produced by fractional distillation of natural gas at low temperatures and pressures, ethane produced by the electrolysis of sodium acetate, propane by the action of propyl iodide on a zinc copper couple and carbon dioxide produced by sulphuric acid on a solution of potassium carbonate were used. Care was taken to rid all of impurities. Fractional distillation at low pressures and temperatures was used for final purification. Starting with a pressure of 80 mm. with a correction of 0.1 per cent, the correction for the product Pv at 31,000 mm. was 12.5 per cent for CH_4. For ethane the correction at 23,000 mm. was 37.7 per cent, for propane at 5723 mm. 10.6 per cent and for carbon dioxide at 26,500 mm. the correction was 22.2 per cent. Bureau of Mines, Washington, D. C. Address H. Foster Bain, Director.

Hydraulics A3-21. Flow in Riveted Steel Pipe. Bulletin No. 8 of the Engineering Experiment Station, Purdue University reports the investigation of the flow of water through galvanized spiral riveted steel pipe of diameters of 4 in., 6 in., 8 in., and 10 in. The Bulletin is by Prof. F. W. Greve and R. R. Martin. The friction drop was determined in 40 ft. of pipe and velocities varied from less than 2 ft. per sec. to over 20 ft. per sec. Experiments showed that the loss in head could be expressed by the equation

$$h_1 = m(v)^n$$

where v = velocity in ft. per sec.
h_1 = loss of head in ft.

The value of n is about 1.9 and the value of m varies with the diameter of pipe; n also varies slightly with the diameter of pipe. When the flow is against the laps the following relations hold for n and m:

$$n = -0.877\,d^2 + 0.832d + 1728$$
$$m = 0.0515/d^{0.926}$$

When the flow is with the laps the following hold:

$$n = -1.954\,d^3 + 2.166\,d^2 - 0.464d + 1.845$$
$$m = 0.0488/d^{0.799}$$

The values of f in the equation

$$h = \frac{f\,l}{d}\,\frac{v^2}{2g}$$

was found to vary with the velocity of flow and the size of pipe. The Bulletin gives tabulated values of this factor. The experiments show that when the flow is with the laps the resistance is practically the same as for clean cast-iron pipe. Engineering Experiment Station, Purdue University. Address A. A. Potter, Director.

Metallurgy and Metallography A16-21. Tensile Properties of Steel at High Temperatures. The investigation made at the Bureau of Standards on the test of alloyed steels at elevated temperatures will be presented at the September Convention of the American Society for Steel Treating under the title Tensile Properties of Some Structural Alloy Steels at High Temperatures. Four steels containing about 0.40 per cent carbon were tested at various temperatures between 20 deg. cent. and 550 deg. cent. The samples were of four kinds:

(*a*) Plain carbon steel; (*b*) 3½ per cent nickel steel; (*c*) steel containing 3 per cent nickel and 1 per cent chromium; (*d*) steel containing 1 per cent chromium and 0.2 per cent vanadium. The steel containing chromium showed a greater resistance to weakening by increase of temperature to about 550 deg. cent. than either of the other two steels. At high temperatures chromium-vanadium steel is preferred from the standpoint of high tensile strength and limit of proportionality. The carbon and the 3½ per cent nickel steels behave in a similar manner so that the nickel appears to have no effect. The report also refers to the type of fractures obtained in testing these steels at various temperatures. Typical microphotographs are included. Bureau of Standards, Washington, D. C. Address S. W. Stratton, Director.

Metallurgy and Metallography A11-21. EFFECT OF HEAT TREATMENT ON MECHANICAL PROPERTIES OF CERTAIN STEELS. A report of tests made at the Bureau of Standards on heat-treated carbon-molybdenum and chromium-molybdenum steels will be presented at the September Convention of the American Society for Steel Treating. The following resnlts are obtained on a steel containing 0.20 per cent carbon and 1 per cent molybdenum:

1 For each maximum temperature there is a critical rate of cooling which will lower Ar_1. The higher the temperature the slower is the rate of cooling to produce the lower transformation. By whatever combination this is produced the position of the low point is fixed within a narrow temperature range to about 525 deg. cent. Rapid cooling will suppress this point.

2 A high temperature transformation is observed slightly above and almost merging with Ar_3 when the steel is cooled from temperatures at or above 960 deg. cent. at a rate of approximately 0.15 deg. cent. per sec. At a faster rate this is not observed.

3 Ar_2 is fixed at about 760 deg. cent. independent of maximum temperature of heating or rate of cooling.

4 The most suitable temperature from which to harden this steel is in the neighborhood of about 910 deg. cent. Free ferrite is found after quenching from 830 deg. cent. but the observed changes in mechanical properties with rise in quenching temperature within this range cannot be explained by known changes in carbon or iron, by differences in the rate at which the steel passes through the critical ranges resulting from changes in initial temperature of cooling, by unsatisfactory hardening or by the lowered Ar_1 for they are opposite to the changes found in plain carbon steel under similar conditions.

5 For the production of definite tensile strength, water quenching is preferred on account of the higher proportional limit, ductility and impact values, and hence better tensile properties are obtained for a given impact resistance.

6 Raising the quenching temperature from 910 to 980 deg. cent. does not materially alter mechanical properties when subsequently tempered at a relatively high temperature of 540 deg. cent.

Steel containing 0.27 per cent carbon, 0.9 per cent chromium, 0.5 per cent molybdenum give the following results:

1 The Ar_1 transformation is first split and lowered when cooled from 960 deg. cent. or 1000 deg. cent. at about 0.15 deg. cent. per sec. The low point is observed at 480 deg cent. In water quenching from the highest temperature a lower hardness is obtained than when similarly cooled from 960 deg. cent. In this respect chromium-molybdenum steel behaves similarly to the molybdenum steel except that the changes are produced from higher temperatures.

2 In normalizing the chromium-molybdenum steel a low limit of proportionality and impact resistance are obtained when using temperatures above 780 deg. to 845 deg. cent.

3 The fact that no material changes in tensile or impact properties are produced by oil quenching the chromium-molybdenum steel from a wide range of temperatures when subsequently tempered at 540 deg. cent has been confirmed. To produce high impact values in the hardened steel a tempering temperature in the neighborhood of 650 deg. cent. is required. Bureau of Standards, Washington, D. C. Address S. W. Stratton, Director.

Petroleum, Asphalt and Wood Products A7-21. Fourth Semi-Annular Motor Gasoline Survey of the Bureau of Mines shows a drop of seven cents in the cost per gallon from the previous year with an increase of more than 380,000 gal. in the first five months of 1921 over the similar period of 1920, the total amount handled being over two billion gal. The 115 samples showed the specific gravity of 0.747, the same as last year, with distillation temperature practically the same as last year, the average boiling point being 268 for 1920 and 269 for 1921. The per cent recovered was 96.6 for 1921 and 96.7 for 1920. The distillation curve falls slightly below the 1920 average which was below the Federal Specifications. Bureau of Mines, Washington, D. C. Address H. Foster Bain, Director.

Wood Products A9-21. GLUE FOR DAMP PLACES. Casein glues are so water-resistant that plywood glued with them will stand exposure to warm damp atmospheres for many months while animal and vegetable glues will resist such atmosphere a very short time. After a long time the water-resistant glue loses its strength due to the hydrolysis of the casein brought about by sodium hydroxide. Forest Products Laboratory, Madison, Wis. Address Director.

Wood Products A10-21. DRY KILNS. Progressive dry kilns consume less heat per lb. of water evaporated and reach highest heat efficiency in drying from green state, especially when supplied continuously with green lumber of one thickness and class. Compartment type of kiln is more flexible and affords greater control over drying conditions, giving more constant temperature, humidity and circulation with variation in wind and weather. It is fitted to meet varying requirements of different materials and is useful where exact and careful drying is required. Forest Products Laboratory, Madison, Wis. Address Director.

B—RESEARCH IN PROGRESS

The purpose of this section of Engineering Research is to bring together those who are working on the same problem for coöperation or conference, to prevent unnecessary duplication of work and to inform the profession of the investigators who are engaged upon research problems. The addresses of these investigators are given for the purpose of correspondence.

Mechanics B6-21. FATIGUE OF MATERIALS. The first step of the investigation by Prof. H. F. Moore and others on the fatigue of materials is nearly completed and a bulletin is in preparation. Address Dean C. R. Richards, Engineering Experiment Station, University of Illinois, Urbana, Ill.

Mechanics B7-21. UNSYMMETRICAL SECTIONS. The action of angles, channels and other unsymmetrical sections in relation to tension and bending is to be investigated by Prof. A. N. Talbot. The study will be made by obtaining strain-gage measurements at various portions of the piece when subjected to load. Address Dean C. R. Richards, Engineering Experiment Station, University of Illinois, Urbana, Ill.

Properties of Engineering Materials B3-21. TENSILE PROPERTIES OF STEELS AT HIGH TEMPERATURES. The investigation of the properties of low-carbon steel used in boiler construction has been completed and the results prepared for publication. These will be presented under the title: Effect of Temperature, Deformation and Rate of Loading on the Tensile Properties of Low-Carbon Steel below the Thermal Critical Range, by H. J. French. Bureau of Standards, Washington, D. C. Address S. W. Stratton, Director.

Railway Rolling Stock and Accessories B3-21. CHILLED CAR WHEELS. The experiments directed by Prof. J. N. Snodgrass and conducted by H. F. Goldner are almost complete. The investigation of the properties of chilled car wheels was undertaken to determine the strains arising from the mounting of the wheel on its axis, the strains resulting from the static or wheel loads, the strains resulting from the flange pressure, the ultimate breaking strength of the wheel flanges and the strains due to the temperature gradients in the wheels as caused by brake application. In making the experiments, the load was applied as nearly as possible in the same manner as the application in service; the strains were measured by the Berry strain gage and the data obtained from the tests were considered in relation to the material, design and other features of the car wheel. Address Dean C. R. Richards, Engineering Experiment Station, University of Illinois, Urbana, Ill.

C—RESEARCH PROBLEMS

The purpose of this section of Engineering Research is to bring together persons who desire coöperation in research work or to bring together those who have problems and no equipment with those who are equipped to carry on research. It is hoped that those desiring coöperation or aid will state problems for publication in this section.

D—RESEARCH EQUIPMENT

The purpose of this section of Engineering Research is to give in concise form notes regarding the equipment of laboratories for mutual information and for the purpose of informing the profession of the equipment in various laboratories so that persons desiring special investigations may know where such work may be done.

E—RESEARCH PERSONNEL

The purpose of this section of Engineering Research is to give notes of a personal nature regarding the personnel of various laboratories, methods of procedure for commercial work or notes regarding the conduct of various laboratories.

C. B. Roberts Engineering Company E1-21. The C. B. Roberts Engineering Company has equipped a laboratory for investigating petroleum problems on commercial-size samples. The company is preparing to handle all phases of oil-refinery developments, to make petroleum analysis and process work, to design refineries and prepare estimates for the same, to construct and operate refineries and to make report on betterment work and appraisal as well as do research work of a general nature. Address C. B. Roberts Engineering Co., 19 Milk St., Boston, Mass.

F—BIBLIOGRAPHIES

The purpose of this section of Engineering Research is to inform the profession of bibliographies which have been prepared. In general this work is done at the expense of the Society. Extensive bibliographies require the approval of the Research Committee. All bibliographies are loaned for a period of one month only. Additional copies are available, however, for periods of two weeks to members of the A.S.M.E. These bibliographies are on file at the office of the Society.

Petroleum, Asphalt and Wood Products F5-21. Serial 2269 of the Reports of Investigations of the Bureau of Mines contains a list of recent articles on Petroleum and Allied Substances compiled by E. H. Burroughs. These bibliographies are prepared monthly. Bureau of Mines, Washington, D. C. Address H. Foster Bain, Director.

CORRESPONDENCE

CONTRIBUTIONS to the Correspondence Department of MECHANICAL ENGINEERING are solicited. Contributions particularly welcomed are discussions of papers published in this Journal, brief articles of current interest to mechanical engineers, or suggestions from members of The American Society of Mechanical Engineers as to a better conduct of A.S.M.E. affairs.

Supplementary Reading for Consulting Engineers

The January, February and May 1921 issues of MECHANICAL ENGINEERING contained correspondence concerning a list of books for supplementary reading by students in industrial management. In connection with this discussion there has been received a list arranged by The Thompson & Lichtner Co., consulting engineers, of Boston, Mass., designed to familiarize its men with existing literature on subjects of particular interest to them.

This list contains the following group of ten books which are to be read in the order given and reviewed:

How to Use Your Mind, Kitson
Industrial Leadership, Gantt
Primer of Scientific Management, Gilbreth
Scientific Management, Drury
Theory and Practice of Scientific Management, Thompson
Shop Management, Taylor
Work, Wages and Profits, Gantt
Scientific Management and Labor, Hoxie
Administration of Industrial Enterprises, Jones
Industrial Organization and Management, Diemer.

Supplementary lists on the following subjects are given, from which each man may choose according to his needs:

Production
Sales
Industrial Relations
Accounting
Construction
Plant and Lighting
General.

The Engineer's Part in Fire Protection

TO THE EDITOR:

Now that the production-at-any-cost engineer of wartimes has been superseded by the economical-production engineer, the questions of violation of the various rules of fire prevention and safety should be taken up and the effect of such violations shown.

Practically every class of engineering is affected by the degree of consideration given these questions. The architect or engineer who designed the building which was fire-resistive except for unprotected steel roof members, placed a lasting insurance charge on that building at a saving in construction cost which would have been covered in a five-year period by the difference in insurance rates.

This difference in cost of insurance is illustrated by several plants where so-called temporary ordinary-joisted brick or frame additions were built on to fire-resistive or slow-burning buildings, without fire divisions between the two sections. For instance, a fire-resistive building of the finest type had first a 300-ft. joisted-brick addition, then another 300-ft. joisted-brick addition, and finally a 150-ft. frame addition, making a total length of about 1750 ft. in one fire area. The original building would have rated at not exceeding 20 cents per hundred insurance, but now the entire building rates at $1.50, and in view of the fact that this particular building and contents is valued at about $6,000,000, the cost of this mistake is approximately $78,000 a year; three fire walls across these buildings at $5000 each would have given a rate of about 90 cents, or a saving of $36,000 a year.

The buildings of the war period have also given the highest record of losses in sprinklered risk resulting from additions which were built and not equipped with sprinkler protection. Records of insurance companies show that 22 per cent of their sprinklered-risk losses are due to fires started in unsprinklered areas not cut off by fire walls from the sprinklered areas.

Going into the matter of protection, we have a sad record of losses resulting from poor placing of fire hydrants, generally too close to buildings, and insufficient number of fire hydrants as a whole. There have also been numerous cases of protection systems which have not been equipped with adequate water supplies, mainly through lack of sufficient reserve pumps.

Many production engineers consider that the man who sends the finished material to the loading dock is the only really important factor in the plant, disregarding entirely the maintenance engineer, who keeps the plant in condition so that it may produce, and the fire-prevention and protection engineer, who keeps it in existence. The fire-prevention or protection engineer and the safety engineer are generally placed on the non-productive payroll, whereas the proper organization for any plant is to have the maintenance, the fire-prevention, and the safety engineer either on an equal with the production engineer, or closely associated with him.

The average fire loss per capita in the United States has not been below $3 in the last 10 years and was about $5 for the year 1920. This is a national overhead which of course affects all factors of production. We have also the overhead cost resulting from accidents causing decreased efficiency, decreased production and increased labor turnover. The reduction of these overhead costs depends to a great extent on the knowledge and efforts of the architect, the designing engineer, and the construction engineer, and their coöperation with the man who has specialized in fire prevention and protection, and with the safety engineer.

Detroit, Mich. W. M. WELLS.

The Fuel Situation

TO THE EDITOR:

The possibilities along the line of natural gas, fuel oil, city gas, producer gas, both raw and clean, as well as powdered coal and stokers for furnace heating, are known by only a limited number, and the activities of The American Society of Mechanical Engineers could be broadened to cover various kinds of fuel through the whole range of their application.

Natural gas is fast disappearing and cannot be considered as an industrial fuel. Even today many industries that were built around natural gas are forced to look for some other fuel to replace it. Due to the cheapness of this fuel little or no thought was given to its economical application, and many instances may still be found where furnaces are very inefficient. Fuel oil, raw gas, clean gas, powdered coal and stokers have all replaced in a greater or less degree some of the natural gas with good results, but only in a few instances have the highest, or anywhere near the highest, possible economies been obtained.

Fuel oil, because of its price and the ease with which high temperatures may be obtained, has been widely used. We know, however, that our fuel-oil supply is getting shorter every year, and there are very few shops in the country where fuel oil is used that much attempt has been made to economize on the fuel in any other way than by burner design. Where high temperatures are desired such furnaces run with flames issuing from the vents and doors. Often furnaces of this kind run with hearth temperatures of 800 to 1000 deg. above that required by the metal itself, and no thought is given to a better product to be obtained by other methods without decreasing the production. Fuel oil in low-temperature work is very wasteful, as used at present, because of the excess of air that is normally used to hold the temperatures down.

the necessarily high price of this fuel.

Raw gas has done much to reduce the cost of manufacture and increase the overall efficiency of furnace application, but there are few installations other than the open-hearth that receive the attention they should.

Clean gas has made some strides in fuel economy for furnace application and it must not be confused with the gas-power proposition.

Because of the fact that the flame temperature of clean producer gas is lower than that of many other fuels, it has been necessary to apply some effort to reach desired results with this gas, but that effort has always paid in the increased economies that may be obtained.

and the work is of such a late date and has received so much publicity that not much need be said for this method of fuel economy.

Stokers have been used for a number of years on various kinds of furnace work, and the best results obtained were in instances where the stoker and furnace were taken as a whole.

The whole point is that the fuel economies possible in all fuels are so great that increased efficiencies of 25 to 30 per cent can be obtained, rather than a few per cent under boilers. No one of the fuels now used is a cure for all ills, each having a certain field of application, but by getting together on this subject we can determine wherein added economies may be obtained and what is the best method of fuel applicatio n for various kinds of work.

Dayton, Ohio. EARL E. ADAMS.

WORK OF THE A.S.M.E. BOILER CODE COMMITTEE

THE Boiler Code Committee meets monthly for the purpose of considering communications relative to the Boiler Code. Any one desiring information as to the application of the Code is requested to communicate with the Secretary of the Committee, Mr. C. W. Obert, 29 West 39th St., New York, N. Y.

The procedure of the Committee in handling the cases is as follows: All inquiries must be in written form before they are accepted for consideration. Copies are sent by the Secretary of the Committee to all of the members of the Committee. The interpretation, in the form of a reply, is then prepared by the Committee and passed upon at a regular meeting of the Committee. This interpretation is later submitted to the Council of the Society for approval after which it is issued to the inquirer and simultaneously published in MECHANICAL ENGINEERING.

Below are given the interpretations of the Committee in Cases Nos. 357 to 363 inclusive, as formulated at the meeting of June 23, 1921, and approved by the Council. In accordance with the Committee's practice, the names of inquirers have been omitted.

CASE NO. 357

Inquiry: Are the circulating pipes connecting down-draft furnaces to the shells of boilers to be considered as integral parts of the boilers themselves or as connecting piping outside of the boiler? Screwed connections as now used give both economy in space and flexibility.

Reply: It is the opinion of the Committee that such connections between boiler shells and down-draft furnaces are integral parts of the boiler, so that the requirements in Par. 268 for pipe openings leading from a boiler need not be met, and screwed connections may be used. The requirement for the minimum number of threads given in Table 8 applies to all pipe connections and should be met, as well as all other requirements which bear on the structure.

CASE NO. 358

Inquiry: Is it permissible, under the requirements of the Boiler Code, to deliver feedwater into the shell of a boiler through what is known as an induction valve or spray nozzle located in the steam space and arranged to deliver the water through a number of constricted openings in the form of a spray?

Reply: It is the opinion of the Committee that such an arrangement at the end of the feed pipe for delivery of the feedwater to the boiler will not meet the requirement of Par. 314, which requires that the feed pipe shall have an open end or ends to prevent stoppage by incrustation, unless the combined area of the passageways for the flow of the water is at least equal to the area of the feed pipe and these passageways are so arranged that it will be impossible for them to become clogged by incrustation.

CASE NO. 359

Inquiry: Is it permissible, under the requirements of the Boiler Code, with heads stayed by through rods, to attach the rod ends to the heads by a special form of gland nuts that provide for packing between them, as shown in Fig. 18?

Reply: It is the opinion of the Boiler Code Committee that this construction does not conflict with the requirements of the Boiler Code, provided that the area of the nut bearing surface against the plate is greater than the minimum cross-sectional area of the rod. The value of C for this construction shall be 135.

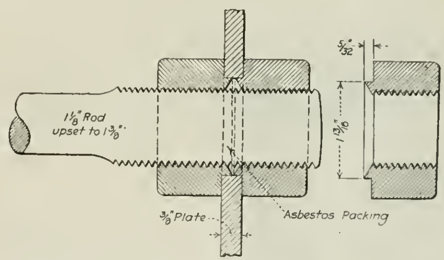

FIG. 18 SPECIAL FORM OF GLAND NUTS FOR ENDS OF THROUGH RODS

CASE NO. 360

Inquiry: Is it necessary, under Par. 254, to remove heads, open up girth seams and remove manhole frames, braces, etc., in order to remove burrs formed by drilling or reaming of rivet holes?

Reply: Par. 254 refers specifically to the plates and butt straps at longitudinal joints.

CASE NO. 361

(Annulled)

CASE NO. 362

Inquiry: (*a*) What is the minimum thickness of plates used for dome heads that is permitted under the requirements of the A.S. M.E. Boiler Code?

(*b*) Is it permissible to stay the heads of domes, where they are flat, by using angle or channel irons?

Reply: (*a*) There is no limit specified in the Code for the minimum thickness of dome heads except as given in Par. 17.

(*b*) The heads of domes, if flat, shall be stayed in accordance with Pars. 199 to 233 inclusive.

CASE NO. 363

Inquiry: Is it permissible, under the requirements of the Boiler Code, to apply a manhole in the upper head of an h.r.t. boiler over 40 in. in diameter, the area of the head surrounding the manhole to be stayed as provided in Pars. 203*e*, 214 and others applying to stayed surfaces?

Reply: In accordance with Par. 264, a manhole shall be placed in the upper part of the boiler shell, boiler head or dome head, of a fire-tube boiler over 40 in. in diameter. When applied to the head of such a boiler, the head shall be stayed in accordance with Par. 203*e*.

Impressions of Industrial Russia

Glimpses of the Workers and Factories in Moscow and Petrograd—The Present Economic Situation and the Doubtful Outlook for Russian Industries

By ROYAL R. KEELY, NEW YORK, N. Y.

The position of Russia in European reconstruction is of vital interest to American engineers and industrial executives, and there is lack of reliable information as to conditions in Russia. Mr. Royal R. Keely, Mem. Am.Soc.M.E., returned from nearly two years in Russia, as this issue of MECHANICAL ENGINEERING was about to go to press. Upon being convinced of American interest in Russian developments, he prepared this statement of some of his impressions. Coming from an engineer and an experienced observer in industrial plants, it will be accorded authority.

Mr. Keely is a graduate of Cornell University in electrical engineering and received the degree of M.M.E. in 1901. After three years' experience in power-plant and electrical railway machinery, he served as professor of engineering at the University of South Dakota for two years, as consulting engineer in Sioux Falls, South Dakota for one year, and as city engineer of Edmonton, Alberta, N.W.T., Canada, from 1906 to 1909. Since that time he has acted as professor of electrical engineering at the Nova Scotia Technical College, consulting engineer for the Tabor Mfg. Co., Philadelphia, and in 1913 he opened an office as consulting management engineer.

Mr. Keely went to Russia in 1919 and for eight months visited the industrial plants in and about Moscow. He was imprisoned for a year and upon his release he had a four-months' opportunity to observe the operation of the industries of Russia.—EDITOR.

ROYAL R. KEELY

THE Bolshevik revolution came in Russia in October 1917. I arrived in Moscow on September 18, 1919, so their organization plans and methods of industrial operation had had ample opportunity to get well under way.

The general plan of the Bolsheviki is that of wholesale centralization. There are various departments such as the departments of state, war, and education. "Means of Production and Ways of Communication" are handled by the department known under the name of the Supreme Council of National Economy.

The Metal Department with Ludwig Martens, former Bolshevik agent in this country, at its head, includes all metal-producing and working plants. One division of this department is devoted to standardization, and groups of engineers are attempting to establish ideal standards for screw threads, bolts and nuts, and chemical and physical standards for iron, steel and alloys. They also propose the standardization of an ideal form of the automobile, locomotive, etc., as a step in simplifying and standardizing manufacturing.

If Russian industries were completely destroyed and the present régime had the power to build everything anew, then a plan of standardization might be practiced. The average Russian thinks that the problem is 99 per cent solved after these idealistic fantasies are drawn up. The details necessary for effective execution are entirely ignored. When elaborate electrification plans were worked out for entire Russia, the work was looked upon as substantially ended. Electric plows are devices which cannot be of value in Russia for some generations. Yet a considerable number of engineers, clerks and stenographers are wasting immeasureable time on their development.

There are two important reasons for these fantastic schemes. One is that the simple-minded officials are pleased by these elaborate scientific projects and encourage the work. The other reason is that every individual in Russia is assigned to a particular job, from which he cannot move without official permit. Therefore engineers, scientists, and educated people find it necessary to create jobs. It is more interesting for them to work out these elaborate theoretical plans than it is to clean streets or split wood.

Central Stores Department

In the organization of industry, one particularly interesting and theoretically fine department called the "Producemet" has been set up. This corresponds in our practice to a general stores department. Here are recorded the location, quality and quantity of all raw materials in the entire nation, also the quantity and kind of finished product and its location. The records for all manufactured products are turned into this office automatically, as well as all demands for them. Under the Bolshevik scheme, each individual is to work for the government, and in return for this service he is to be supplied with the necessities of life. If one wants a typewriter he puts in his demand at the central stores department, where they decide whether he is entitled to a typewriter. If his request is granted, the machine is ordered to be shipped from the nearest point of production or storage. In the the central office is a very elaborate and complicated card system, but the staff is entirely incompetent and untrained and the records are never up to date and are entirely unreliable. In the winter of 1920 I visited this department. There were about 2000 employees, but at the time of my visit it was extremely cold, the temperature in the rooms being around the freezing point. Only a very small fraction of the total number of employees were at their desks, a few typists attempting to write on their machines with gloved hands.

The Professional Unions

The professional or trade unions are attempting to take an important part both in the educational and industrial control. The government is theoretically a government of the workers and peasants. These professional unions are therefore a part of the government and are consequently under the control of the Bolshevik party. They fix the rates of pay and also the piece rates and premiums. Their plan has been the establishment of a fixed base rate which varies according to the production and general efficiency of the workers. Bonuses for increased production have been ineffective because of the extremely difficult working conditions. There is always the demand for increase of wages, and with each increase of wages the cost of living goes up in approximately the same proportion. It is interesting to note that the market price on food, clothing and daily necessities remains about constant as compared with the American dollar. The value of the ruble drops in proportion to the increase in wages.

The workmen have their Soviets in each factory. These men, illiterate and inexperienced in executive and technical work, have power over the engineers and members of the old technical staff. This fact, in connection with the shortage of raw material, fuel, instruments and tools, makes any effective result almost unthinkable.

For any degree of success from such a gigantic centralized organization for production and transportation it would require a nation of able, honest and efficient people, all unselfishly working for the public good. Graft and corruption were proverbial under the old régime in Russia, and under the new, the adverse economic conditions have greatly increased dishonesty and thievery.

Street Railways and Telephones

The official working hours are from 10 to 5, but scarcely any one in Moscow works longer than from 11 to 4. The entire evenings are spent in repairing shoes, sawing and splitting wood, carrying water, removing ashes, and running to various departments for food rations from the government. In the winter of 1919–20 the street-car system did not operate. Last summer and winter there was a limited street-car service, but only certain employees who were able to secure official passes were allowed to ride. The telephone service is almost entirely destroyed. All telephones have been removed from private apartments.

Discontent among Employees

With the whole of Russia reduced to a state of starvation, it is painful to see great cities like Moscow and Petrograd without any useful productive effort. I was surprised to see the general discontent among all employees. The average man is only interested in making a job for himself to comply with the compulsory labor requirements. Every one in Russia who has any education, training or ability wants to leave the country, and would if the opportunity was given. I had rather a close acquaintance with the Russian-American Tool Company, made up of a few Russian immigrants to America who had a little coöperative factory here in the United States. In 1918 their patriotism led them to return to Russia, taking their American machinery and equipment with them. They established a tool factory in Moscow in the fall of 1919 which is looked upon as a most successful example of the new industry, although its production is only one-tenth of what it should be. I renewed my acquaintance with these men in the summer of this year, just before leaving Moscow. They are all extremely dissatisfied with their experience in Russia. The employees receive one and a half Russian pounds of black bread daily, a little soup for their noon lunch, and once a month four or five pounds of meat, some vegetables and fish. This is better than the workers in other factories get. Also their pay is better. Yet these men are selling their personal effects in order to provide daily necessities, and this was in the summer when the living conditions were easier. They did not dare consider the difficulties of the coming winter.

I have seen and talked personally with hundreds who returned to Russia under the patriotic impulse. I have not found a case where they were not making every effort to get back to America.

Conditions in Moscow Factories

The big Goujon factory, devoted to structural steel, wire rope, etc., and employing some six or seven thousand men before the revolution has now but a thousand employees. The old technical men who are trying to direct the work have very great difficulties. They are short of raw material, fuel, food, trained workers, etc. They have no control of discipline. I asked the chief engineer to tell me the greatest need of his plant, and he replied, "A proprietor."

The AMO automobile factory is a new plant with the very finest buildings and American equipment. Six or seven thousand men should be employed for full operation. They now have about 1000 employees, and these are engaged in trying to complete the plant, which was not entirely ready when the revolution came, and in repairing a few automobiles. Their output is about what would be expected from an American garage of 15 or 20 men. They tried all the winter of 1919–20 to make a cylinder casting for a White motor truck. In May 1920, after dozens of experiments, they had one casting which they failed to machine.

The International Harvester Company's factory near Moscow is the only factory I found which had not been "nationalized," but even here the manager's hands were tied, because for all the essentials of manufacturing he must depend on the Bolshevik government. He takes his orders from the Bolshevik government and manufactures on a cost plus 10 per cent basis, out of which he must pay his expenses and those of the executive staff. He permitted the Workmen's Committee to have charge of social matters, sanitation, hospitals, food, etc., but technical questions are decided by the technical staff. By his energy and tact he has maintained discipline and achieved some success. The government failed to supply this plant with fuel. They then allowed the manager to take a train of cars to the forests and bring back the necessary wood. For his furnaces he required coal and coke. Rickoff, president of the Supreme Economical Council, said to him, "We cannot get this coal for you. We will give you a train and you can go for the fuel yourself." The manager took the train to the mines under a soldier convoy, and came back with enough fuel to keep the furnaces going for the immediate future.

Locomotive Repairing

At one time I told Lomonossoff[1] that the fate of his country hung primarily on transport, and that transport, in turn, depended on locomotive repair. Orders were subsequently issued and locomotives were placed in all sorts of factories which lacked equipment or workmen for this kind of work, and any appearance of regular production was thereby destroyed. The men were given a bonus when a locomotive was repaired and they were allowed to go to the country and bring in food. This brought about the most inefficient results. The locomotive was turned out quickly, making a good record for the factory, but would come back shortly for another repair. At the time of the revolution there was a big wire cable factory near Moscow. Here, for several months, about 1000 men were employed getting the plant ready. In the spring of 1920 the first locomotive was completed and the men took this engine with a train of cars and went several hundred miles into the country for food, disrupting any scheme of transportation schedules.

During all this time, the big locomotive works in Russia were standing idle!

Petrograd Factories

Bad as the manufacturing conditions are in Moscow, the prospects there are better than in any other part of Russia. In Petrograd the big Tregolnik Rubber Company plant employing 38,000 men before the revolution is entirely idle. In the Baltic Shipbuilding Plant only a little repair work is being done. At the time Petrograd was threatened by the opponents of the Bolsheviki a large part of the machinery was evacuated from Petrograd, but the machines were taken apart without being marked and so "scrambled" that it was entirely impossible to reassemble them again. The Siemens-Schuckert Works, employing about 40,000 men is now essentially idle, doing only a little repairing. In the Arthur Koppel plant in Petrograd regular production was stopped, and at the time of my visit early in 1920 they were making only a few turf-excavating machines.

Classes in Russia

The whole population of the present Soviet Russia may be divided into five classes. The first includes what one may call the political idealists and these have been instrumental in laying out the general organization plan for the present government. Their number is very small. The second class is made up of a few hundred who are now ruling with an iron hand. These men are living better than they have ever lived before, occupying the best houses, having the best food and clothing and the use of automobiles. The third class comprises the remainder of the Bolshevik membership, said to number about 500,000, most of whom are not in sympathy with the party. Finding their families cold, hungry and ill clad, and seeing their Bolshevik friends better situated, they join the party. The fourth class includes the peasants, the majority of whom may be said to be strongly against the present régime. The fifth class includes former wealthy people, the educated groups, professors, scientists and engineers. It seems to be the aim of the Bolsheviki to exterminate this class. Therefore their living conditions are extremely bad. The Bolsheviki have been successful in only one thing and that is in pulling every one down to the level of the lowest of prerevolutionary times. The only exceptions to this are the first two classes named above.

Position and Problems of Engineers

The position of the engineer in Russia today under the Bolshevik régime is exceedingly difficult. Conditions do not permit constructive work by engineers.

I can refer to a great many instances where engineers of my acquaintance are procuring enough food and fuel for their families only by selling their books and instruments. They are living huddled in squalid quarters, doing their cooking on small sheet-iron stoves which also serve as heaters. They carry supplies up five or six flights of stairs, after hauling them miles from the storehouse. They are occupying minor clerical jobs in the factories or government offices to get their food allotment, or are doing menial mechanical work in smaller villages where food and fuel conditions are slightly better. The chief engineer of the AMO automobile works was theoretically in charge of production. This

MECHANICAL ENGINEERING

A Monthly Journal Containing a Review of Progress and Attainments in Mechanical Engineering and Related Fields, The Engineering Index (of current engineering literature), together with a Summary of the Activities, Papers and Proceedings of

The American Society of Mechanical Engineers

29 West 39th Street, New York

The Relation of the Engineer to Public Utilities

M. E. Cooley

Dr. Pritchett, President of the Carnegie Foundation, says in his recent report on the law profession:

> If organized society is to continue, the great mass of human beings who compose it must be fed and clothed and warmed and transported.

Mr. H. G. F. Spurrell, in Modern Man and his Forerunners, defines civilization as:

> ..... the mode of life in a territory which is maintaining a larger population than could live on the land if the people were not organized to develop its resources.

Spurrell's "civilization" under modern conditions becomes Pritchett's "organized society."

On the walls of the Engineering Societies Library one may read that:

> Engineering is the art of organizing and directing men, and of controlling the forces and materials of Nature for the benefit of the human race.

Thus we see that engineering is a factor in civilization—so important a factor, indeed, that modern civilization, as we know it, could not exist without engineering. That is to say, if the work of the engineer were to be wiped out of existence—annihilated—desolation would fall upon cities and adversity sweep the land. Civilized people would be pursued by famine and plague, suffering and sorrow being in proportion to their degree of culture and refinement. Only those living close to nature would be unaffected.

But more specifically what part does the engineer perform in Dr. Pritchett's conditions for the continuation of organized society, to wit, feed, clothe, warm and transport human beings? The engineer may not himself grow the materials for food and clothing, but he does provide the mechanical means for converting many of them into food and clothes; and for transporting them from source to consumer. He also provides the means for warming and transporting human beings. In short, the engineer is very largely responsible for what Dr. Pritchett says is necessary for the continuation of organized society.

Not to eulogize but to point to another kind of service for the engineer, let us consider his relations to public utilities, meaning thereby steam and electric railroads; telegraph and telephones; electric lights and power plants; water and gas plants, and the like. These are as vital to our modern civilization as the circulating and nerve systems are to the body. The engineer having done his part in designing and building them is no longer concerned except as he may be called on to help operate or extend them in the future. That is to say, engineers are not doing their duty to the public in refraining from taking part in questions affecting the cost and value of utility properties and rates to be charged for service.

Public utilities are in the main owned by public-service companies. There is, however, a distinct trend toward public ownership. Behind may be changing social conditions, but in the foreground are dissatisfaction with the service and the rates charged. Out of misunderstandings have grown quarrels and fights which have for years occupied our courts and commissions. The question here is not the merits for either side but how to bring about mutual understanding. What are the factors which should govern in determining proper rates for service? and where is the line to be drawn in questions of public ownership? Although largely engineering in character, these questions apparently have not interested engineers very much. Why?

No one will question that the engineer, having been instrumental and largely responsible in building utility properties, is, or should be, well qualified to say what items go into their building and the cost of the items. In the absence of engineers, except a few, this important field of investigation has been occupied by others, who honest though they be, are ignorant of many important things. Thus courts and commissions have been reaching conclusions and rendering opinions which are not in every case based on all the facts.

The public is not to be blamed for its attitude, when those really qualified to have an opinion are silent. Public-service corporations have been charged too many times with high-handedness in the past. But they are for the most part the sins of the fathers; for whatever the public may think about it, the responsible officers of public-service companies are not today engaged in robbery;—they are fighting for existence. Hundreds of companies have gone into receivers' hands and the end is not yet. But that is not the worst of it. The public in working out its indignation may deal itself a blow as well as the company. It should remember that Sampson in pulling the house down to avenge himself on the Philistines also killed himself.

It is common knowledge that because of the quarrels between the public-service companies and the public no more money can be had for investment in utilities at low interest rates. Such investments are now regarded as too much of a gamble. It is safe to say that had it been foreseen that the charge allowed for service would be insufficient to meet necessities capital would not have been forthcoming and the utility would not have been created. And it is also safe to say that could it now be done without too serious loss capital would be withdrawn from public utilities. Public ownership would no longer be an issue but would become a necessity.

One of the contentions has to do with the amount of capital invested in the utility. The books show one amount, the appraisal another; and the public not knowing which is right accepts neither. Considering the imperfect methods of keeping accounts in the early days, difference of opinion among engineers and accountants as to the propriety of including certain items of cost is scarcely to be wondered at. The subject of appraisal and valuation is largely the development of the past twenty years, and comparatively few have engaged in this field of research. If engineers, accountants, commissions and courts cannot agree, how reasonably expect the public to be satisfied?

Why this lethargy of engineers in a matter of such vital importance? It certainly cannot be indifference. More likely it is due to the engineer being an idealist—an idealist in the sense that he is wrapt up in his constructive work, his interest in its problems being so great as to exclude other matters. Whatever the cause it is time the engineer roused himself and took more active part in public affairs. The public wants the opinion, not of individual engineers, but of the profession. More than that, the public wants the help that engineers can, because of their professional knowledge, render as citizens.

M. E. Cooley.

THE essential unity of science is being more clearly recognized each day. Chemistry and physics merge in the study of the radioactive elements, the advances in colloid chemistry, the reactions promoted and the syntheses effected under the action of light, and in the important and expanding applications of electricity to process industry in many fields. All the experimental sciences are coming to lean more and more heavily upon the mathematician and to draw more generally upon each other to adjust or support their findings. Chemotherapy, the X-ray, radium, and synthetic drugs have placed new powers in the hands of the physician. Biology has now to reckon with vitamines, adrenalin, and the extraordinary influence upon the living organism of the chemical products of the thyroid and other glands.

With this general trend so clearly defined it is not surprising that the chemist and the mechanical engineer are finding new points of contact and developing a new sense of mutual dependence in their industrial activities. Bessemer supplies the engineer with cheap steel. Thomas and Gilchrist make available great bodies of phosphatic iron ores. As the requirements of the engineer become increasingly exacting the chemist provides tungsten, vanadium, and nickel steels. These the engineer turns to new account and by the development of high-speed tools revolutionizes the art of metal cutting. The engineer demands lightness with strength, and chemistry supplies aluminum. From its storehouse come new abrasives, better adhesives, more effective lubricants.

The burning of coal is a chemical operation, and to be carried out at high efficiency the process must be under chemical control. The whole fuel situation today is charged with impending change. It is plastic, but it cannot be shaped by the mechanical engineer alone. The problems involved in powdered coal, colloidal fuel, the Trent process, low-temperature distillation, gas enrichment, and motor fuel, to mention only a few of the factors in the complicated situation, demand for their solution the close coöperation of the chemist and the engineer. Similar coöperation is required if we are to secure the best results in the layout of piping and equipment, the selection of materials of construction, and the adaptation of structures to the needs of industry.

Chemistry is an experimental science, and chemists are trained to devise and conduct the experiments designed to secure answers to many of the questions of the mechanical engineer. The mechanical engineer deals with matter in the mass, and chemistry is concerned directly with the properties of the matter with which he deals. Here is the meeting ground on which the chemist and the mechanical engineer may coöperate to mutual advantage.

A. D. Little.

Dinner to American Deputation of Engineers

Two hundred of the elected officers of American engineering societies assembled in New York on October 10 to "welcome home" the deputations of American engineers which visited England and France this summer to convey greetings to the engineers of those countries. The names of those who went abroad and an account of the trip were published in the August issue of Mechanical Engineering, page 558.

The form of welcome was a dinner at the Pennsylvania Hotel at which Mr. J. Vipond Davies, president of the United Engineering Societies, acted as toastmaster. Distinguished guests included M. Gaston Liebert, French Consul General; Captain G. H. Armstrong, British Consul General; G. G. Clapperton, representing the British Institution of Electrical Engineers; Prof. Jacques Cavalier, spokesman for the French universities; and Governor James Hartness of Vermont.

Following speeches by Mr. Swasey, chairman of the delegation, and by Captain Armstrong, Mr. Charles F. Rand and Dr. Jewett described the functions which took place in England and Mr. John R. Freeman and Major Dwight those in France.

M. Liebert, on behalf of the French Government, presented medals commemorative of the mission's visit to that country to the presidents of the four national engineering societies, to the general chairman of the mission, and to the chairmen of the several society delegations.

Dr. J. W. Richards, professor of metallurgy at Lehigh University and one of the foremost engineers of the country, died suddenly of heart trouble on October 12. Dr. Richards was born July 28, 1864 at Oldbury, England. He was educated in the Central High School, Philadelphia, the University of Heidelberg, the Mining Academy at Freiberg, Germany, and Lehigh University. He taught at the latter institution for over thirty years.

Dr. Richards was an authority on aluminum, a legal expert in chemical and metallurgical cases, had an international reputation in various branches of metallurgical technology, and was the author of many books on metallurgical and other engineering subjects.

He was a member of the United States Assay Commission in 1897; representative of The Franklin Institute to the International Geological Congress held in Russia in 1897; member of the jury of awards, department of chemistry, of the National Export Exhibition at Philadelphia in 1899; member of the jury of awards and chairman of the metallurgical subjury, Panama-Pacific International exposition, 1915; member of the United States Navy Consulting Board, 1915–1918.

He was a charter member of the American Electrochemical Society, its first president in 1902 and 1903 and its secretary since 1907. He was a member of The Franklin Institute of Philadelphia, president of the chemical section, 1897–1899, and professor of electrochemistry of the institute, 1907–1910.

Dr. Richards was a member of the Faraday Society, Deutsche Bunsen Gesellschaft, American Chemical Society, American Institute of Mining and Metallurgical Engineers, former vice-president of the institute and chairman of the iron and steel committee since 1914, member of the Iron and Steel Institute of Great Britain, of the American Iron and Steel Institute, of Société de la Chimie (France), of the American Institute of Chemical Engineers, and honorary member of the American Electroplaters' Association. He was a member of the Board of Engineering Foundation and a member of the National Research Council. He was representative of the American Institute of Mining and Metallurgical Engineers on the joint conference committee of the F.A.E.S.

Announcements of the DeLamater Ericsson Tablet Committee

The DeLamater Ericsson Tablet Committee announces that it has had a communication from the Board of Directors of the Association of Swedish Engineers (Svenska Teknologforeningen), Stockholm, Sweden, stating that they will hold a celebration of the sixtieth anniversary of the Battle of the *Monitor* and *Merrimac* simultaneously with the celebration which the Committee will hold in New York and Washington on March 9, 1922, as announced in the September issue of Mechanical Engineering. It is expected that members of the Royal Family and the American minister to Sweden will be present at the Swedish memorial meeting.

The Committee hopes by means of these contemporaneous celebrations to still further enhance the already very cordial relations between Sweden and this country, and hopes that American engineers and other patriotic citizens will coöperate with the Committee to this end.

DeLamater Ericsson Tablets on Exhibition

America's Making, Inc., under the auspices of the New York State and City's Departments of Education, will exhibit three centuries of immigrant contributions to our national life at the 71st Regiment Armory, New York City, October 29 to November 12. At the request of the Swedish Section, the DeLamater Ericsson Tablet Committee has been asked to make arrangements for having the DeLamater Ericsson Tablet models, the medals and diplomas presented to Captain Ericsson by this and other countries, and the Ericsson models of solar engines and other mechanisms now in the possession of The American Society of Mechanical Engineers, to form a part of this exhibit. The DeLamater Ericsson Tablet Committee, whose address is Engineering Societies Building, 29 West 39th St., New York, N. Y., consists of H. F. J. Porter, *Chairman*, Oakley R. DeLamater, Fred. A. Halsey, Axel S. Hedman, Ernst Ohnell, Henry R. Towne, and Chas. Vezin.

A.S.M.E. Annual Meeting in New York, December 5 to 9, Will Stress Importance of Industrial Waste Elimination

Professional Divisions to Discuss Avoidable Wastes—Strong Sessions on Education—Students to Conduct Session—Social Events to be Emphasized—Registration Fee

THE recent report of the Committee on Elimination of Waste appointed by the American Engineering Council emphasized the great responsibilities to be borne by engineers in elimination of industrial wastes in this country. Following out the recommendations in the report that each technical society give this matter intensive treatment, the program of the 1921 Annual Meeting of the A.S.M.E. will stress the engineering phases of the problem. The leading session will point out the necessity for waste elimination and develop the principles of standardization and stabilization which are essential in the movement. The professional sessions will contribute to the strength of the program by emphasizing, in a concrete technical way, the steps that can readily be taken to more effectively utilize our national resources. The names of the speakers for the leading session cannot be announced at the present time, but the Management Division, which is arranging the program, promises that the general question of waste elimination will be discussed in a broad, constructive manner. An inspiring session is assured.

Professional Sessions

The tentative program on page 755 shows an intimate relation between the leading session and the technical sessions whose programs have been arranged by the various Professional Divisions. The complete programs for some of these sessions are given. The Aeronautic, Ordnance and Forest Products Divisions have not entirely completed their lists of speakers. The Aeronautic Division contemplates a discussion of the economic possibilities of commercial aviation and two technical papers on the materials used in airplane construction; one of these, on cables, will be given by R. R. Moore. The Ordnance Division will present a paper by Colonel J. W. Joyes, Chief of the Technical Staff of the Ordnance Department, in which avoidable wastes in ordnance manufacture will be pointed out. The Forest Products Division will demonstrate how several lumber manufacturers have successfully reduced waste in the various processes involved in the conversion of the log into forest products. The experience of the Southern and West Coast districts will be related and the need for still further reduction in wastes will be emphasized.

The limitations of the Engineering Societies Building make it exceedingly difficult to hold more than three simultaneous sessions. Accordingly, the Council has this year granted permission to extend the meeting for five days, and the leading session will be called to order at 2.00 p. m. on Monday afternoon, December 5. As a further step to properly utilize every available moment, morning sessions will begin promptly at 9.30. It is believed that this will reduce the necessity for adjourned sessions.

Education

The importance of industrial education will be developed thoroughly at this meeting. Two sessions are to be held, one under the auspices of the Committee on Education and Training in the Industries, which will present a program pointing out the great needs for education in the industries. Dean R. L. Sackett of Pennsylvania State College will present in one of the papers a résumé of the status of industrial education throughout the country. The second paper, by D. C. Buell, of the Railway Education Bureau, Omaha, Neb., will relate the steps taken by the railroads of the country for the training of their men. It is earnestly hoped that this program will bring out discussion that will enable the committee to plan a constructive program for future industrial training.

The second session on education will be a joint meeting with the Society for the Promotion of Engineering Education. Prof. Dugald C. Jackson is in charge of the program, which will give an opportunity for mechanical engineers to discuss with teachers the requirements of an adequate technical-school training in mechanical engineering.

Students' Session

A new and important development in Annual Meeting projects will be launched at the coming December convention. The Committee on Relations with Colleges has charge of a session at which the papers will be prepared and presented by students. Discussion will be limited to students and the meeting will be conducted by students.

Honorary Members

The honorary memberships which have been granted to Henry R. Towne and Nathaniel G. Herreshof will be formally bestowed on Tuesday evening, following the address of President Carman.

Business Meeting

The business meeting has been scheduled for Wednesday, December 7. The entire day will be given over to the discussion of the policies of the Society and especially of the new constitution which appeared in Sectoin II of the August issue of MECHANICAL ENGINEERING. The business meeting is the especial opportunity afforded for the membership to discuss Society matters. The program has been arranged without conflicting sessions so that there will not be the excuse that opportunity is not granted to each member to stand on his feet and comment upon what the Society is or is not doing. The strength of the A.S.M.E. has been built on the activity and interest of its members, and its future growth depends on increasing this activity and interest.

Social Events

A program of social events somewhat more elaborate than that of last year has been planned for this meeting. In addition to the presidential reception, which will be held Tuesday evening, there will be a ladies' tea and dance on Wednesday afternoon, an informal get-together dinner for the membership on Wednesday evening, and a dinner dance on Thursday evening. Friday evening will be devoted to college reunions and the following institutions are planning events: Cornell University, University of Illinois, Lehigh University, Massachusetts Institute of Technology, University of Michigan, New York University, Pennsylvania State College, Polytechnic Institute of Brooklyn, Purdue University, Rensselaer Polytechnic Institute, Stevens Institute of Technology, Worcester Polytechnic Institute, and Yale University. The ladies' tea will be served Wednesday, December 7, at 3.30 on the fifth floor of the Engineering Societies Building. The place for the informal get-together dinner on Wednesday evening has not yet been chosen. An informal program will be given during the smoker which will follow the dinner. The dinner dance will be held at the Hotel Astor. In view of the great popularity of this function in previous years it is probable that reservations will be required well in advance of the meeting. The circular, which will go out to the membership early in November, will give complete information regarding such reservations. On Thursday a luncheon is planned for members of Sigma Xi honorary scientific society.

Excursions will lead to points of technical interest about New York. The Friday afternoon excursion will be one of interest to the entire membership.

The ladies will be made especially welcome at this meeting. A reception committee will be in constant attendance and opportunities will be given to visit interesting points of the city.

Special Railroad Rates

Arrangements are being made to provide special railroad rates for members attending the meeting. Complete information regarding this will be in the Annual Meeting circular. It is requested that every member who is coming to the Annual Meeting make

TENTATIVE ANNUAL MEETING PROGRAM

New York, December 5-9, 1921

(Other subjects or changes to be announced later)

Monday Morning, December 5
Local Sections Conference
Council Meeting

Monday Afternoon, December 5
Leading Session: Elimination of Waste in Industry

Monday Evening, December 5
Session on Education and Training in the Industries

Tuesday Morning, December 6 (Simultaneous Sessions)

POWER WASTE SESSION

Heat Balance of:
- Connors Creek Station of the Detroit Edison Co., C. H. Berry
- Colfax Station of the Duquesne Light Co., C. W. E. Clarke
- Delaware Station of the Philadelphia Electric Co., E. L. Hopping
- Hell Gate Station of the United Electric Light & Power Co., J. H. Lawrence and W. M. Keenan

MACHINE SHOP WASTE SESSION

Waste in Machine Industry (two papers), J. A. Smith and J. J. Callahan
Art of Milling, John Airey

RAILROAD WASTE SESSION

Avoidable Waste in Operation of Locomotives and Cars, Wm. Elmer
Avoidable Waste in Locomotives, Jas. Partington
Avoiding Waste in Car Operation, W. C. Sanders

Tuesday Afternoon, December 6 (Simultaneous Sessions)

MANAGEMENT WASTE SESSION

Making Work Fascinating, W. N. Polakov
The Process Chart, F. B. and L. M. Gilbreth

FOREST PRODUCTS WASTE SESSION
(Authors to be announced)

Excursions

GENERAL SESSION

Testing of Emergency Fleet Boilers Using Oil Fuel, F. W. Dean
Stresses and Deformation in Flat Circular Cylinder Heads, A Mathematical Analysis, Maj. G. D. Fish
Control of Centrifugal Castings by Calculation, R. F. Wood

Tuesday Evening, December 6
Presidential Address and Reception
Conferring of Honorary Membership

Wednesday Morning, December 7
Business Meeting

Wednesday Afternoon, December 7
Business Meeting
Ladies' Tea and Dance

Wednesday Evening, December 7
Dinner and Informal Get-together

Thursday Morning, December 8 (Simultaneous Sessions)

FUEL WASTE SESSION

Boiler Plant Efficiency, Victor J. Azbe
Fuel Saving in Relation to Capital Necessary, Jos. Harrington
Developments in Boiler and Furnace Design, D. S. Jacobus
Producer Gas for Industrial Furnaces, W. B. Chapman

MATERIALS HANDLING WASTE SESSION

Industrial Waste in Handling of Material, H. V. Coes

STUDENT SESSION
(See page 754)

Thursday Afternoon, December 8
Joint Session with Society for Promotion of Engineering Education
Excursions

Thursday Evening, December 8
Dinner Dance

Friday Morning, December 9 (Simultaneous Sessions)

TEXTILE WASTE SESSION

Report on Second World Cotton Conference, Chas. T. Main
Hidden Wastes in Textile Mills, T. P. Gates
Research Results in Cotton Spinning, A. N. Sheldon
Economy in Textile Drying, B. R. Andrews

ORDNANCE WASTE SESSION
(Authors to be announced)

AERONAUTIC WASTE SESSION
(Authors to be announced)

GAS POWER WASTE SESSION

Porting and Charging of Two-Stroke Oil Engines, Louis Illmer
Paper by E. A. Sperry (title to be announced)

Friday Afternoon, December 9
Council Meeting
Excursions

himself familiar with the provisions regarding these rates so that the entire membership may receive the benefit therefrom. The awarding of the one-half fare rate on the return trip depends upon the number of members who apply for certificates before leaving their homes. These certificates are turned in at the Annual Meeting headquarters and if a sufficient number are received the one-half fare rate is awarded. It is important, therefore, that every member attending the Annual Meeting make request for the certificate.

Registration Fee

The Committee on Meetings and Program, with the approval of the Council, has authorized the levying of a registration fee of $1.00 for each member and $2.00 for each male guest. Ladies are to be registered without charge. This registration fee has been imposed only after very careful consideration of the various principles involved and knowing that the membership thoroughly believes that the meetings of the Society should be at least partially self-supporting.

Snow Removal From City Streets a Problem For Engineers

A.S.M.E. Materials Handling Division Discusses Fundamentals of the Problem and Various Methods of Melting, Compressing and Conveying Snow

The removal of snow from city streets is a problem requiring adequate machines, thorough organization and forceful administration. An engineering discussion of this problem took place on Friday evening, September 23, at a meeting of the Materials Handling Division of The American Society of Mechanical Engineers held in the Engineering Societies Building under the auspices of the Metropolitan Section.

Walter S. Finlay, Jr., chairman of the Metropolitan Section, opened the meeting and after a short business session relinquished the chair to Nathan C. Johnson, member of the Executive Committee of the Materials Handling Division.

The first speaker was Henry L. Doherty, whose interest in the problem had been aroused by his observation of removal methods used at the time of the heavy snowfall in New York on February 20, 1921. Mr. Doherty's views are expressed in an editorial in the August issue of Mechanical Engineering and in his correspondence with various officers of The American Society of Mechanical Engineers, printed copies of which are available on application at Society headquarters. In his address, Mr. Doherty pointed out the immensity of the problem of removal of a snowfall in a large city of even a few inches. In New York City a snowfall of 12 inches means a total weight of approximately 3,000,000 tons of snow on the 3500 miles of streets. Upon the assumption that snow must be handled so as to impede traffic in the least possible degree and for the shortest possible time, Mr. Doherty suggested, as first aid only, that footpaths should be made at the curb, throwing the snow toward the building line, that one-way streets be decided on, and that on two-way streets road paths should be cleared on the sides, piling the snow in the center, and sidewalks cleared at the curb. All of this should be done after a careful survey is made of every foot of New York streets and maps prepared showing where snow may be piled. To avoid hauling, which seems exceedingly expensive, Mr. Doherty suggests the making of snow briquets. He calls attention to the fact that ice is ten times as dense as snow and that with a briquetting mechanism a 12-inch snowfall on a 60-foot street may be piled in a wall three feet wide and three feet high where it will not interfere with traffic and will melt without inconvenience to vehicles or foot passengers. Mr. Doherty also discussed other methods of removal and advocated the use of the method which proved most economical for each particular locality.

John P. Leo, commissioner of street cleaning of New York City, emphasized the importance of snow removal to maintain the health and safety of the city. He described the experience in New York during the winter of 1919–20 when the traffic in the business section of the city was practically tied up, resulting in the development of a commission under the chairmanship of Fire Chief John Kenlon to suggest a solution of the problem which was tried out during the winter of 1920–21. The city was mapped out in districts, to each of which tractor plows and motor trucks were assigned and located in the fire-engine houses in these districts. Routes were laid out and the plows patrolled these routes from fixed points. Trucks were loaded from the piled snow and dumped into the nearest sewer. The cost of removal of a million and a half cubic yards was one million, eight hundred thousand dollars in 1920–21. From this experience it is now planned to clear and load the snow as it falls, using plows, conveyor loaders and trucks to get the snow into the nearest sewers. This can be done best as the snow is falling, when there is generally very little freezing. The Department of Street Cleaning is at work on a mechanical loading apparatus which will pick up the snow and deposit it in the trucks to be carted away. A number of slides were shown of the apparatus used in 1919–20 and 1920–21 for the handling of snow in New York City.

The Fundamentals of the Problem

John T. Fetherston, former commissioner of street cleaning of New York City, analyzed the snow problem into the following three elements:

1 For what depth of fall, density, rate, duration and occurrence of snow shall the city reasonably prepare each winter?

2 What are the allowable maximums for the design of the organization and apparatus?

3 The next pertinent or possibly impertinent question to ask is, how many hours or days should reasonably be allowed for the removal of the snow from the scheduled area, meantime keeping the streets free for the movement of traffic, in order that the citizens of the town may judge reasonably of the efficiency of the organization, methods, procedure, management and apparatus of the municipality?

As to the solution of the problem he made the following statement:

If the mechanical engineers would voice the sentiments of the public by setting up physical standards for snow work in New York and other cities, the people would then be in a position to judge of the real efficiency of their chosen officials, on a basis of fact.

Moreover, the officials would undoubtedly welcome a reasonable standard by which the results of their work could be judged. No such standard exists and it is unfair and unjust to condemn officials for the times they fail to vanquish a fifteen-inch snowfall followed by zero weather with six-inch equipment and underfed, poorly clothed, inadequately shod humans.

The Solution of the Snow Problem:

1 Set up the standards of quantity, quality, time and conditions as a basis for the design of organization, methods, procedure and equipment.

2 Provide the personnel and the apparatus to meet the conditions. Make the work attractive to available forces by offering pay commensurate with the work and the results secured.

3 City officials come and go. There have been eleven commissioners of street cleaning in twenty-three years since Greater New York was organized—an average official life of about two years to learn the city charter and the details of an organization comprising 7,000 men, serving 6,000,000 people scattered over an area of 140 square miles of territory.

The solution of the snow problem and other municipal problems will come nearer realization when engineers mark the targets for the officials to shoot at and exercise their duties as prospective leaders of public opinion by presenting, say to the New York Charter Revision Commission, the underlying principles of successful administration applicable to public office in such form as may readily be translated into law. Methods, apparatus and devices alone will never solve the snow problem, but organization, capable administration and effective execution with the right man behind the gun will score many bull's-eyes.

At the close of Mr. Fetherston's talk, John Kenlon, chief of the New York Fire Department, gave a dramatic account of the struggle with the snow during the winter of 1919–20. As the result of this struggle, which was led by the Fire Department, Chief Kenlon was made head of the Commission which formulated plans for handling the snow during the winter of 1920–21.

To emphasize the great fire risk developed by blocking the streets to the movement of fire apparatus, G. W. Booth, of the National Board of Fire Underwriters, gave an estimate of building valuations in New York City. In the area from the Battery north to Fortieth Street the total valuation for buildings and contents was given at two billion, two hundred and twenty-three million, four hundred thousand dollars. In the area between Fourth and Seventh Avenues from Fourteenth to Fortieth Streets there is a total of six hundred and thirty-six million dollars involved. Although there is an almost continuous line of sprinklered fireproof buildings through the center of the city, there are many old and poorly constructed buildings on both sides. It is in these buildings that fire might start which under adverse circumstances, such as snow-blocked streets, would spread to adjoining buildings and blocks and become a conflagration. In conclusion Mr. Booth pointed out that the Fire Underwriters are constantly keeping in mind that sometime impossibilities often become actualities. The prompt response of the fire department is an extremely important factor, and snow removal may be the controlling element in such response during a severe storm.

Devices for Snow Removal

The remainder of the program was devoted to the consideration of details of methods for snow removal. The chairman read a letter from Thomas A. Edison in which he pointed out that some

of it, pass it into a compressor and deliver blocks of ice into the gutter behind.

George L. Sawyer, western manager of the Barber-Greene Company, Aurora, Ill., emphasized the importance of a solution of the snow-handling problem to every city throughout the country. He grouped the processes involved in the removal of snow in two major operations. The first is that of meeting requirements of commerce and convenience by opening a lane for traffic, and the second is that of meeting the requirement of public health to the extent of entirely removing the snow. Mr. Sawyer recited some of the efforts being made throughout the country to solve the snow problem as follows: Adaption of the kerosene pressure torch, the introduction of steam into water hose to melt snow, flame throwers, and snow melters of the furnace type of similar to those used for reheating asphalt. These methods require artificial channels such as gutters, etc., for the disposal of the melted snow. The heating units must be portable and are not practical unless the fuel is cheap. In the field of purely mechanical devices Mr. Sawyer mentioned the plow, snow compressor, rotary plow, the crane and clamshell bucket, and the combination of the belt conveyor and scoop. For the transportation of the snow itself he suggested the common vehicles, used in combination with river, stream, gutter or sewer. Mr. Sawyer pointed out that in three of the largest American cities in the past winter successful demonstrations of snow removal have been made. The first procedure was to open up the principal thoroughfares for traffic as quickly as possible, lanes being cleared of snow by means of sweepers or plows and the snow being deposited in piles in the center of the street. The snow deposited was loaded mechanically into trucks and taken to streams or sewers. The snow loader used in these three cities consisted of a 32-in. belt conveyor, installed at an angle of approximately 25 deg. on a continuous-tread tractor. At the lower end the 32-in. section was increased to a scoop-shaped section having a width of 6 ft. Motive power was obtained from the 25-hp. gasoline engine which moved the entire machine as well as the conveyor. A truck could be located immediately behind the snow loader so that only the width of the machine was needed for snow removal. This machine described by Mr. Sawyer permitted trucks to be moved out at intervals of from two to six minutes. He estimated that savings over manual removal, based on reduced labor cost and increased truck "turnovers," were as high as $550 per snow loader per eight-hour shift. Mr. Sawyer recommended the use of mechanical methods during the night because of decreased traffic at that time. At the close of his talk Mr. Sawyer suggested that the A.S.M.E. would render an important service if it collected and sifted information on this subject.

Mr. D. L. Ellis, assistant engineer of the Great Northern Railroad, Seattle, Wash., presented a scheme for using a gas-electric rotary snow plow for taking up the snow, shooting it to the side of the street or dropping it in trucks alongside of the plow. Mr. Ellis' device is shown in Fig. 1.

Chairman Johnson read abstracts of contributions from Mark A. Guigou, New York, N. Y., W. Lehman, Milwaukee, Wis., and E. C. Donner, Pittsburgh, Pa.

Mr. Guigou's device, shown in Fig. 2, is an indication of a design believed to be practicable by the author, with which it is proposed to compress snow to from one-quarter to one-eighth its initial volume without the use of an excessive amount of power. The figure indicates a double-walled or jacketed tubing machine cylinder with the gasoline engine exhausting through this jacket, thus utilizing the exhaust heat to melt the snow adjacent to the walls of the machine cylinder and facilitating its passage through tubing machine in a hard column which could be delivered directly to the truck immediately in the rear of the tractor. In this way each truck could be loaded to its full-weight capacity.

Mr. Lehman's contribution suggested, first, the mapping of the city to show where snow could be piled with least inconvenience; second, a shovel of 3 cu. yd. capacity, like a steam shovel but compressing the snow in the shovel by the forward movement of the truck, so that with a fall of 1 ft. or less a truck travel of 20 to 40 ft. would be necessary to fill the dipper. The shovel would then be lifted and dumped into a truck. Mr. Lehman estimates that this device could be operated at a speed of two miles per hour, that the machine would weigh about four tons and cost from three to four thousand dollars.

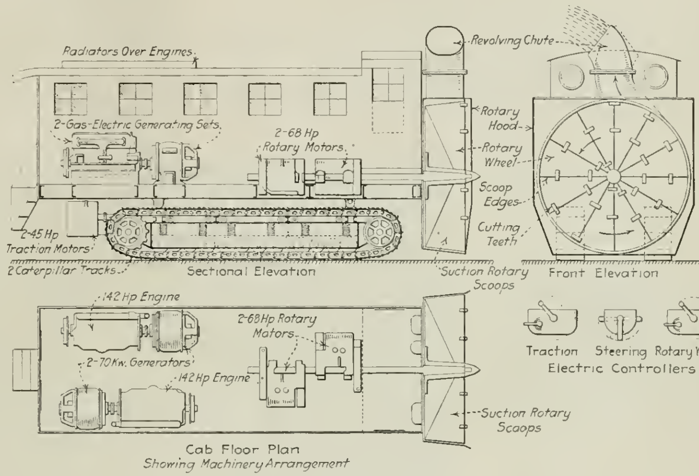

Fig. 1 Ellis Gas-Electric Rotary Snow Plow

E. C. Donner suggested a scraper of street width drawn by a tractor or trolley car and followed by two machines consisting of scoops and screw-type compressors for briquetting the snow in cylinders. These briquetting machines will be followed by trolley or gasoline trucks to collect the ice cylinders.

John Flodin, of Quincy, Mass., presented lantern slides showing a modification of loaders successfully used for handling gravel, coal, etc. The conveyor, which should be mounted on the necessary truck or tractor, has at its front end a blade or scoop attached to start the snow on the belt. Provision is made for the conveyor chute to be lowered while passing under elevated structures, trolley wires, etc. Mr. Flodin also presented a sketch of a simple power-driven snow-shoveling device. To take care of the possibility of snow remaining on the street until it forms ice, Mr. Flodin suggested an ice breaker consisting of a rotary multi-tooth clipper or breaker, a tilting and dumping scoop and a melting hopper into which the scoop is discharged. All these parts are mounted on a truck or tractor to be steam-driven, Exhaust steam and waste gas is used to melt the ice.

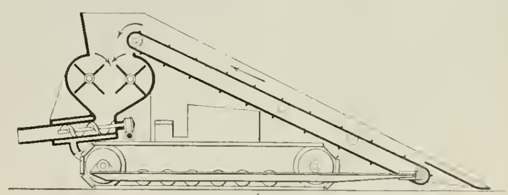

Fig. 2 Guigou's Machine for Compressing Snow to a Quarter of Its Original Bulk

Experiences in Snow Melting

A. Parker-Smith related some experiences in snow melting. On the basis of 14,000 B.t.u. per lb. of soft coal or gas-house coke, and using the latent heat of fusion of 1 lb. of snow or ice or 140 B.t.u., Mr. Parker-Smith estimated that one ton of coke at $10.50 per ton delivered should melt 100 tons of snow. Estimating a 75 per cent heating efficiency, the fuel cost of a well-packed two-horse-truck load of snow would be twenty-one cents. On the same basis Mr. Parker-Smith estimated the fuel cost of melting the snowfall on a Fifth Avenue block as $10.50.

He also told of snow melters built thirty years ago, some of which were tried out in New York City. One of these set up in Hancock Square was used to melt 86,000 lb. of snow in four hours, consuming 1000 lb. of coke. Difficulties of operation were found to be dirt in the water jacket and clinkers which clogged the draft. In conclusion Mr. Parker-Smith stated that snow can be melted more cheaply than it can be carted to the river from any but riverside sections.

In the discussion David Moffat Myers suggested melting by use of hot water in congested districts. Assuming 80 per cent efficiency and 16 per cent loss in mixing, with coal at $8 per ton, Mr. Myers estimated the cost for melting the snow would be two cents per cubic foot.

Chief Kenlon called attention to the fact that the weather in New York City may be severe, which makes the melting of snow exceedingly difficult. He emphasized the necessity for machines being compact and stated as his opinion that the problem would not be solved by the adoption of any one method but rather by the utilization of the best method for any particular locality. He believed that a sewer is the best, most practical conveyor for removing snow, although the sewers of New York south of 59th Street are generally inadequate.

Further Studies Contemplated

Upon motion by Mr. Doherty, the meeting passed a resolution that a committee be appointed by the Materials Handling Division to study the snow-removal problem and present its findings for the benefit of the cities of the country. This committee is to plan its own course and raise the money necessary for the execution of its plans.

In his closure Mr. Doherty pointed out that the removal of snow by melting is the most difficult method because it involves handling in addition to the melting process. Mr. Doherty stressed particularly the idea that there is great waste in handling snow unless it is compressed. Trucks or trailers cannot be loaded to weight capacity with snow as it falls. As an emergency measure Mr. Doherty recommended that snow should not be moved from private property into the street. He believed that it would be better to pile snow on the sidewalk and level it off as pedestrians can walk on twelve inches of snow as easily as on one inch. In the use of heat, direct contact is the most effective method. Salt and calcium chloride have proven ineffective and impractical. Snow removal seems to be a mechanical problem and from this point of view briquetting is advisable in order to get greatest effectiveness from conveying vehicles. Mr. Doherty further pointed out the advantages that sunlight has in snow removal especially when dust or other black material covers the snow thereby reducing the reflecting effect of the sun and absorbing the heat of the sun.

Devices not Presented at the Meeting

A number of devices were described by members who could not be present, some of which are worth attention. Edward A. Smith of West Englewood, N. J., suggested the application of heat to snow after the snow is separated into flakes. The device he has evolved includes a revolving wheel which will scatter into a melting chamber of 67,440 cu. ft. capacity a continuous stream of snow 42 in. wide, 12 in. high and 3.9 in. thick. The snow is kept agitated by compressed air and oil is used as fuel. Mr. Smith estimates that 76,500 cu. yd. can be melted in 28 hours. At this rate one hundred machines would be required for Greater New York costing per day twenty thousand dollars for oil, seven thousand dollars for men and one thousand dollars for electric current. Based on the total winter's snowfall of 7,400,000 yd., the season's cost would be $2,220,000, or thirty cents per cubic yard.

Messrs. Thomas Chester and Bernard Kern of Sandusky, Ohio, came to the conclusion that the only successful method of removing snow is one that can be put into operation as soon as one or one and one-half inches of snow have fallen, machines to be kept operating over the same territory during the snow storm. They suggest a sweeper and scraper which can be adjusted to drive the snow to one side where it can be loaded into trucks by hand.

Francis B. Sando, of Newark, N. J., recommended the use of a rotary brush mounted on a gasoline truck which has been used in New Jersey to open the highways.

H. S. Farquhar of Wayne, Pa. has sent in a clipping from *Engineering News* of July 27, 1905, in which his patent granted in 1901 is described. Mr. Farquhar proposed a snow-compressing machine which utilizes a screw. The article relates various attempts at compression in which Mr. Farquhar tried compression between rolls, compression between one roll and stationary plate, compression by forcing between converging surfaces and compression with a piston. The important feature of Mr. Farquhar's device was the idler which was found necessary to keep the compressor screw clean of snow, thereby preventing choking. A report made by Mr. William B. Upton upon Mr. Farquhar's device stated the capacity of the machine to be 4 cu. ft. of snow per min. The compressed block from this machine weighed 55 lb. per cu. ft. which is within $2^3/_4$ per cent of the weight of solid ice. The power consumed was about 0.33 hp.

STEAM-CONDENSING PLANTS

(*Continued from page 716*)

else at greatly increased velocities and correspondingly increased rates of condensation. The main supply of water passes directly through the upper and larger group of tubes and the remainder of the water after passing through the cooler, goes through the lower and smaller group of tubes below the deck or partition.

The rate of condensation in a condenser with all its tubes active was found to vary substantially as the rate of condensation on a single tube, which, as is well known, depends on its diameter and material and the water velocity. With only one passage necessary, an entirely new basis for selection of velocity and tube size is opened to the designer. High velocity or small tubes or both can be used without excessive pump power as would be encountered with multiple-pass construction. Paradoxically, there is more insurance against corrosion, as well as greater protection against reduction of vacuum by scaling and sliming, when working the condenser at the higher and apparently less conservative condensation rates. The author does not wish to imply that excessive pump powers should be used. High capacities and velocities may be obtained without exceeding circulating-pump powers now often used. The circulating-pump capacity is best arranged in twin units so that maximum water quantity and velocity are available in summer and can be reduced in winter by shutting down one pump. Variable or graded circulating-pump capacity is desirable in small as well as large units.

On large units having two water pumps, one of which is shut down in winter, provision can be made for preserving high velocities even with reduced water quantity. At high vacuum with cold water, the top tubes in large condensers do most of the work and therefore the smaller winter quantity should be concentrated on these tubes, thus maintaining high velocities in the tubes which tend to foul and corrode.

In the summer time both pumps supply water to the two nozzles (Fig. 14) serving sections *A* and *B*, and a small quantity of water is supplied the coolers and from them to section *C* at the bottom of the condenser. In winter one pump is shut down, the valve to section *B* shut, and the plates in the deck between *B* and *C* removed thus throwing these two tube banks in parallel so that they both receive water from the coolers. The main water supply is then concentrated on the upper section *A*. This design also has the advantage that at any time the entire capacity of the two pumps may be concentrated on section *A* or *B*, thereby producing extremely high cleaning velocities, also, that either section *A* or *B* can be shut down independently and the water-box covers removed for inspection or cleaning.

Dean Cooley New President of American Engineering Council

Election of Successor to Herbert Hoover Announced at September Meeting of Executive Board of Council—Important Committee Reports and Other Matters Brought Up for Consideration

IN THE recent election, announced at Washington September 30, of Mortimer E. Cooley, dean of the Colleges of Engineering and Architecture of the University of Michigan, as president of American Engineering Council, the executive body of The Federated American Engineering Societies, the organization secures as its leader a man widely and favorably known not only to the engineering profession but to the general public. Dean Cooley has been elected to fill the vacancy caused by the resignation of Herbert Hoover after he became Secretary of Commerce.

Mortimer Elwyn Cooley was born in Canandaigua, N. Y., March 28, 1855, and was graduated from the United States Naval Academy in 1878. Following cruises in the Mediterranean and to Newfoundland, he was ordered to the Bureau of Steam Engineering, where he remained until July, 1881, in the drafting and design department. He was then stationed at the University of Michigan for four years as professor of steam engineering and iron shipbuilding, at the end of which time, at the request of the regents, he resigned from the Navy and accepted the chair of mechanical engineering at the university. He became dean of the College of Engineering in 1904 and of the College of Architecture in 1913.

Mortimer E. Cooley

During the Spanish war Dean Cooley served as chief engineer of the *Yosemite* which acted as convoy and did blockade duty off Santiago, San Juan and the Jamaican coast. For a time following the war he was attached to the League Island Navy Yard, engaged in engineering work.

In 1899 he returned to the university and during the years following undertook a large amount of important appraisal work, the total value of the property with which he has been concerned in appraising being about a billion and a half dollars, of which 85 to 90 per cent has been for the public. From 1907 to 1912 he acted as chairman of the Block Signal and Train Control Board, Interstate Commerce Commission. At the Chicago Exposition he was a member of the Engineering Committee and at the Pan-American Exposition he served on the Committee of Awards.

Dean Cooley was vice-president of the American Association for the Advancement of Science in 1898, president of the Michigan Engineering Society in 1903, a director of the American Society of Civil Engineers from 1913 to 1916, vice-president of the Society for the Promotion of Engineering Education, 1908–1909, and its president, 1920–1921. He became a member of The American Society of Mechanical Engineers in 1884, and served as its vice-president during the year 1902–1903, as chairman of the executive committee, Detroit Section, 1916–1917, and as president of the Society during the year 1918–1919.

Concerning the election of Dean Cooley, L. W. Wallace, executive secretary of the American Engineering Council, said:

> It is indeed gratifying to have such a man as Dean Cooley as president of the American Engineering Council. Dean Cooley is a man of splendid accomplishment both professionally and personally, and is widely and favorably known to the public and to engineers. He is a man that has rendered splendid service to the engineering profession, and it is confidently expected that in his capacity as president of the Federation he will render a still greater service to the public and to the engineering profession by virtue of the larger opportunity.

Committee Reports

The September 30 meeting of the Executive Board of the American Engineering Council was the first to be held at Washington D. C., since its initial meeting, held there November 20, 1920. The presiding officers were Calvert W. Townley and J. Parke Channing of New York, vice-presidents. Approximately twelve hours were devoted to an intensive and earnest consideration of various matters of importance, including the reports of the Committee on Patents, the Committee on Employment, Committee on Government Contracts, and the Committees on Registration and on Classification and Compensation of Engineers.

The Council adopted the report of its Committee on Patents, which urged the passage of the Lampert Bill to remedy conditions in the Patent Office, and approved a resolution expressing the conviction that this bill "provides the least increases in force and salaries which can possibly stop the retrogression of the Patent Office and enable it to make progress toward recovering an efficient condition, and, by increases in the fees for patents, supplies the funds necessary to enable the Patent Office to continue to be self-supporting." The Council will also support the committee in its opposition to the passage of the Stanley Senate Bill which provides for an amendment to the Patent Act, requiring that all alien-owned American patents shall be worked in this country within two years after the granting of the patents.

After a long discussion of the report of the special Committee on Employment, a committee of the Board was appointed to draft resolutions which would crystallize the general thought brought out by the discussion. The committee reported the following resolutions which were adopted:

> Whereas, The need is pressing for a unified employment service for engineers, national in scope, local in application, and financed for adequate service; and
>
> Whereas, The contributions which the constituent societies of The Federated American Engineering Societies are able to make to the Employment Bureau have been found inadequate to provide an Employment Service such as engineers require; therefore, be it
>
> *Resolved:* That the Executive Board of the American Engineering Council endorses in principle a paid employment service but with reduced fees to members of organizations supporting said service; and be it further
>
> *Resolved:* That a Committee of five members of the Executive Board be appointed by the Chairman and that the Boards of Direction of the four founder societies be requested each to appoint a member of its board in order to form a Joint Committee of nine members on Engineering Employment with the power to organize an Employment Bureau, on a plan which will invite the coöperation of interested organizations.

The Committee on Government Contracts made a number of important recommendations. Some of the more significant recommendations approved are:

> 1 That Government work be normally carried out through unit-price or lump-sum contracts, or by the purchase and hire method. Where none of the above methods are applicable to conditions, that the cost-plus method

be used in which the contractor is refunded the actual cost of the work, plus an accorded compensation which increases if the work is done below the estimated cost of the work, and decreases if the work costs more than estimated, but never sinks below zero;

2 That there be appointed by the President an Inter-Departmental Board on Standardization of Contracts, consisting of one representative of each Government department engaged in construction. That this Board recommend policies to govern in the standardization of contracts within each department. Each department should have a small board representative of each bureau engaged in construction, and should seek to unify and standardize contract practices within the Department, and the chairmen of these Departmental Boards might preferably constitute the Inter-Departmental Board, which should be only advisory in character. That when the contracts of each department shall have been by itself thus standardized, that the Inter-Departmental Board consider these contracts and make necessary recommendations to harmonize and secure, so far as feasible, uniformity of practice in the different departments;

3 That all Government officials shall recognize the importance of exerting the utmost efforts to make prompt partial payments on Government contracts at reasonable intervals as stated in the contracts, for all services rendered and materials delivered by the contractor, on the work that has been accepted by the Government inspector;

4 That payment shall in all cases, as far as possible, be made by the official or agency directing the work, and not by an outside accounting or financial agency, in order to avoid the burden on the contractor of delays in payments when made by such an agency not directly concerned with, or responsible for the efficiency, economy and dispatch of the work.

The report of the Committee on the Registration of Engineers was considered and referred back to the Committee for revision. Following a recommendation of the Committee on the Classification and Compensation of Engineers, the Executive Board endorsed the classification of engineers as proposed by the Committee on Classification and Compensation of Engineering Council in its report of December 15, 1919, as in the judgment of the Board generally applicable to all branches of engineering. The Executive Board also authorized the chairman to appoint a sub-committee to make a comparative study of such proposed legislation on this subject for the purpose of presenting to the Council a final report and recommendation for action.

The Executive Secretary was authorized after advice with the Committee on Procedure to organize in such states as may seem to be necessary, State Administrative Committees, thus providing mediums whereby the Federation may obtain quick and direct action pertaining to any of its activities. Such committees would be organized after conference with member organizations. In those states that have an all-inclusive state organization that organization would be requested to recommend representatives on the State Administrative Committee, and in the case of a state where there is not an all-inclusive society, the national organization will be asked to make recommendations. In every instance an effort would be made to obtain representatives of the various branches of engineering and of member societies.

Miscellaneous Business

In view of the general business situation involving the probability of lessening the attendance, it was decided not to hold the engineering assembly planned for January, 1922. The committee in charge of the arrangements was converted into a program and entertainment committee for the Annual Meeting of the Council to be held in Washington in January.

Col. Arthur S. Dwight, official representative of the F.A.E.S. on the deputation of engineers to England and France in June, presented his report, in which he called attention to the active interest in the Federation manifested by British engineers, who have already taken steps to organize the engineers of the Great Britain along the lines pursued by the F.A.E.S.

The resignation of Mr. A. C. Oliphant as assistant secretary was announced. Mr. Oliphant was associated with the Engineering Council previous to the organization of the American Engineering Council and has rendered valuable service in both capacities. He is to become associated with M. O. Leighton and Company, consulting engineers, Washington, D. C.

The applications for membership of the Vermont Engineers' Society and the Associated Engineers of Spokane were approved.

A resolution was passed by the Board approving the decision of the National Board for Jurisdictional Awards in the Building Industry with respect to the award affecting the Brotherhood of Carpenters.

Progress was also reported by other committees. In general it was felt by the attending members of the Board that the work of the Federation was advancing in a satisfactory manner.

Engineering and Industrial Standardization

A Group of Standard Specifications Prepared by the American Society for Testing Materials and the Bureau of Mines Now Under Consideration by the American Engineering Standards Committee

THESE specifications are submitted in accordance with the special provision in the procedure of the American Engineering Standards Committee under which important standards in existence prior to 1920 may be approved without going through the regular process followed in new work. The Committee would be very glad to learn from those interested of the extent to which they make use of these specifications and to receive any other information regarding the specifications in meeting the needs of the industry. Copies may be obtained from the American Engineering Standards Committee, 29 West 39th Street, New York City. Price 25 cents each.

Specifications for Drain Tile

The history of the A.S.T.M. specification for Drain Tile dates back to 1911 when the A.S.T.M. organized its Committee C-6 on Drain Tile to meet two very urgent conditions. The comparatively recent use, on an extensive scale, of very large drain tile in public drainage works for reclaiming wet lands had brought about the unexpected discovery that these large drain tile were quite subject to cracking in the ditch under the weight of the ditch refilling. Also, the extensive production of concrete drain tile, and the resulting controversy between clay-tile and concrete-tile producers as to the merits of the new material made it urgent that additional data be secured.

The first task of the newly organized committee was to plan and conduct a series of investigations covering methods of tests, the determination of desired quality and durability of drain tile, and a study of methods of manufacture and of construction and field specifications. In this work it was actively assisted by the following engineering laboratories: Iowa Engineering Experiment Station, Ames, Iowa; Municipal Testing Laboratory, City of St. Louis, Mo.; University of Wisconsin, Madison, Wis.; Lewis Institute, Chicago, Ill., and the Engineering Laboratory of Edward Orton, Jr., Columbus, Ohio.

The manufacturers of clay and concrete tile coöperated by furnishing materials for tests. The American Society for Testing Materials estimates that these investigations, which extended over five years, from 1911 to 1915, cost at least $25,000.

In 1914 Committee C-6 prepared Standard Specifications for Drain Tile covering strength tests, quality and requirements for strength of tile as used in ditches. These specifications were tentatively adopted, subject to revision. The specifications were revised in 1916 and 1921, the latter revision consisting of a modification of the methods of making the freezing and thawing test as the result of investigations which had been under way for some time. The revised specifications are contained in the 1921 volume of A.S.T.M. Standards.

Methods of Analysis of Manganese Bronze and Gun Metal

Two standard methods of analysis entitled Methods of Chemical Analysis of Manganese Bronze (B27-19) and Methods of Chemical Analysis of Gun Metal (B28-19) have been prepared by Committee B-2 on Non-Ferrous Metals and Alloys of the A.S.T.M. They were based upon several methods in use when the preparation was first undertaken in 1917. After standing as tentative for one year, they were adopted without revision as standard by

the Society in 1919. These specifications may be found in the 1919 volume of A.S.T.M. Standards.

Steel Forgings

Among the eleven standards of the American Society for Testing Materials now before the American Engineering Standards Committee for consideration and approval are:

- Specifications for Carbon-Steel and Alloy-Steel Forgings (A18-21)
- Specifications for Quenched and Tempered Carbon-Steel Axles, Shafts and Other Forgings for Locomotives and Cars (A19-21)
- Specifications for Carbon-Steel Forgings for Locomotives (A20-21)
- Specifications for Quenched and Tempered Alloy-Steel Axles, Shafts and Other Forgings for Locomotives and Cars (A63-21)

Specifications for Carbon-Steel Car and Tender Axles (A21-18).

Specifications A18-21 for Carbon-Steel and Alloy-Steel Forgings are general specifications covering the various classes of carbon-steel and alloy-steel forgings, on which the other specifications have been based with the addition of special requirements to suit the conditions of use. The preparation of these four specifications for forgings dates back to the earliest history of the American Society for Testing Materials. The predecessor of these specifications was the Standard Specifications for Steel Forgings, which were first proposed in 1900 and adopted in 1901 previous to the organization of the present A.S.T.M. by what was then the American Section of the International Association for Testing Materials. Since 1901 there have been several revisions of the work, notably in 1914 with the coöperation of other technical societies and associations, including the former Master Mechanics, Association and the Master Car Builders' Association, now the Mechanical Section of the American Railway Association. The work on alloy-steel forgings other than nickel steel was developed in 1915 as an extension of the previous work.

The specifications for Carbon-Steel Car and Tender Axles, while not included in the forgings series, were developed in connection with this work. In 1914 the Committee of the American Society for Testing Materials in charge of these specifications entered into a coöperative investigation with the Master Car Builders' Association, which led to a revision of the specifications in 1917 that harmonized the requirements in the two organizations. The revised specifications, adopted in 1918, have stood without revision since that date.

In submitting these specifications for approval by the American Engineering Standards Committee, the American Society for Testing Materials has presented data listing the companies, etc. that use them in their entirety or as general specifications upon which have been based other specifications suited to the particular needs. These specifications have been translated by the Department of Commerce into French and Spanish in connection with the development of foreign trade. The revised specifications are contained in the 1921 volume of A.S.T.M. Standards.

Two Cold-Drawn Steel Specifications

The A.E.S.C. has now before it for consideration and approval A.S.-T.M. Standard Specifications for Cold-Drawn Bessemer Steel Automatic Screw Stock (A32-14), and Cold-Drawn Open-Hearth Steel Automatic Screw Stock (54-15).

The materials covered in the two specifications are intended for use in making machine parts in automatic and other rapid-cutting machines in which the highest cutting efficiency is sought, consistent with the nature of the metal specified.

The history of the preparation of these specifications dates from 1909 when a committee was organized by the American Society for Testing Materials to prepare standard specifications for cold-drawn steel. In the discussion of specifications for automatic screw stock it became evident that considerable data were required, particularly with reference to material used for machining at very high speed. The committee accordingly undertook a series of tests to determine features which would affect the working qualities and physical characteristics of standard automatic screw stock. The various consumers represented on the committee placed orders with each of the producers for cold-drawn steel for automatic screw-machine work for test purposes, and a total of about twenty tons of material was thus furnished and tested. These tests were completed in 1913. The specifications covering bessemer stock were adopted by the society in 1914, and, after revision, the specifications for open-hearth stock were adopted in 1915. There have been no revisions since adoption.

These specifications have been translated by the Department of Commerce into French and Spanish for distribution in connection with the development of foreign trade. These specifications may be found in the 1918 volume of A.S.T.M. Standards.

Standard for Permissible Explosives

Standard Specifications for the Testing and Use of Permissible Explosives for Use in Mines, Bureau of Mines Schedule 17, are now submitted for consideration and approval as Tentative American Standards.

These standards are the result of thirteen years' experience by the Bureau of Mines in testing and in assisting manufacturers to develop explosives which offer the minimum hazard, when properly used, in gaseous and dusty mines.

In September 1908, the Bureau of Mines established laboratories, which maintain a trained corps of chemists and engineers conducting routine tests and carrying on special research work to assist in the manufacture and use of explosives. The design of these laboratories, the tests applied to the explosives, and the procedure followed in applying these tests were determined after consultation with the manufacturers and users of explosives in this country and with the officials directing similar tests in England, France, Belgium and Germany.

Standard methods of testing explosives were first published by the U. S. Geological Survey as Explosives Circular No. 1 on May 15, 1909, together with the first list of 17 permissible explosives.

By 1915 data on the testing of upward of 200 explosives had been accumulated, and 134 explosives had been placed on the permissible list. In June 1915 the Bureau of Mines called a conference of representatives of manufacturers of explosives to discuss the methods of testing employed and to determine the tolerances to be permitted in the retesting of field or of manufacturers' samples. As a result of this conference series of tolerances were issued on July 1, 1915.

In November 1920, the Bureau of Mines reviewed the rules and regulations then governing the testing and placing of explosives on the permissible list. In this review the committee took into consideration the data accumulated in the testing of 290 different explosive materials, of which 195 had been classed as permissible. The revised rules formulated as a result of this study were submitted to the explosives manufacturers of the country for their comment and criticism. With these comments in hand a final revision was made and approved as Schedule 17 on April 8, 1921.

Preferred Numbers

As an illustration of a fundamental piece of standardization work based on theoretical considerations which the Germans are attempting, a brief description of their system of "preferred numbers" may be of interest. This is a system of logically-worked-out numbers which are recommended for all new standardization work where numerical values are required. This includes dimensional work, such as the diameters of pulleys and thicknesses of plates, and also for numerical values of speeds, capacities of apparatus, such as kilowatt ratings of motors, etc.

In the accompanying table are given the more important numbers of the system. As an example of their use, if 5 sizes between 10 and 100 mm. are found to be sufficient, the numbers in the first column would be taken, viz., 10, 16, 25, 40, 64 and 100 mm. If 10 are necessary, the numbers in the second column would be chosen. For the range 1 to 10, the decimal would be shifted. A 40 and an 80-series are included in the system, but few cases requiring their use have arisen.

The numbers in each series increase by a constant percentage, i.e., they increase in geometric ratio, or logarithmically, as the diameters in the American Wire Gage. This makes the ratio of the numbers in the 5-series the fifth root of 10, in the 10-series the

tenth root of 10, etc., but rounded to give convenient numbers. The rounded numbers make the use of gage numbers unnecessary.

The Germans regard these preferred numbers as very important as they believe their use will lead to great economies in material, reduce the number of sizes, ranges, etc., simplify the carrying of stocks, facilitate interchangeability, etc.

The following examples of the use of these preferred numbers are from the electrical industry alone: kilowatt ratings of motors, turbo-generators, and transformers; dimensions of carbon brushes; diameters and speeds of pulleys.

TABLE OF PREFERRED NUMBERS

NEWS OF OTHER SOCIETIES

American Institute of Mining and Metallurgical Engineers

The 124th meeting of the American Institute of Mining and Metallurgical Engineers held at Wilkes-Barre, Pa., September 12 to 15, 1921, celebrated the semi-centennial of the Institute, which now has a membership of more than 10,000.

Technical sessions held the first day of the meeting included papers on mining problems, descriptions of plants and coal fields, and several presented under the auspices of the metal section of the Institute, including the following: Application in Rolling of Effects of Carbon, Phosphorus and Manganese on Mechanical Properties of Steel, by W. R. Webster, of Philadelphia; The Thacher Process for Molding and Casting Propeller Blades and Wheels, E. Touceda, metallurgist, Albany, N. Y.; and Acid Open-Hearth Process as Conducted in America, Col. W. P. Barba, Philadelphia, and Dr. H. M. Howe, New York.

The second day of the meeting was spent in an automobile trip through the Wyoming Valley to Scranton, Pa., where the afternoon was devoted to two simultaneous sessions, one dealing largely with electrical features of mining, and the other with Americanization work in connection with mining and metallurgical industries. In the evening another technical session was held at Wilkes-Barre, the subjects under discussion being the Power Installation at Cloverdale, Octagonal Ventilation Shaft of Davis-Daly Copper Co., and the Application of Pulverized Coal to Boilers.

On the following day there was a general joint meeting conducted by the Society of Economic Geologists, a session on mine accounting, a general technical session and an economic geology session, at which many interesting papers were presented.

The meeting closed on September 15 with an all-day excursion to parts of the Wyoming, Lehigh and Southern anthracite coal fields.

Association of Iron and Steel Electrical Engineers

A five-day meeting of the Association of Iron and Steel Electrical Engineers was held at Chicago, September 19 to 24. The technical sessions laid particular emphasis on fuel economy. Standardization also received considerable attention, and an exhibit of electrical devices and inspection trips formed interesting features of the meeting. Only two papers were presented at each session, so that there was ample opportunity for discussion.

The papers dealing with fuel economy were by F. E. Leahy, fuel and experimental engineer of the Carnegie Steel Co., Duquesne, Pa., W. N. Flanagan, steam engineer for the Ohio Works of the Carnegie Steel Co., Youngstown, Ohio, E. A. W. Jefferies, consulting engineer, of Worcester, Mass., and G. R. McDermott, assistant engineer of the Illinois Steel Co., South Chicago, Ill.

Mr. Leahy listed the different forms of fuel used in steel mills, giving the characteristics which fit each one to a different operation, and dealt with possibilities of economy in their transportation, storage and distribution. The discussion brought out the high efficiencies obtained through the use of waste-heat boilers.

The advantages of automatic boiler control were enumerated by Mr. Flanagan, who described one method in which electricity is the controlling medium. The coördination of power from various boilers was believed to be an important factor in conservation of fuel.

The paper by Mr. Jefferies announced his discovery of a method of producing cheap oxygen. This method is based on the idea of carrying on the distillation of the volatile nitrogen from liquid air at the pressure to which the air is originally compressed. The nitrogen, constituting about 80 per cent of the whole volume of the air, may be heated and used in a piston engine to drive the compressor, making external power for operation unnecessary. The applications of this method and the benefits to be derived were discussed.

Mr. McDermott reviewed accomplishments in the utilization of waste gases in steam generation, naming sources of waste heat, and discussed the merits of various types of boilers as absorbers of waste heat.

Other papers presented at the meeting dealt with recent developments in the design of induction-motor starters, the electrification of the steel-mill railroad, and anti-friction bearings in the steel mill.

The report of the Standardization Committee included electric overhead-traveling-crane specifications, general specifications on alternating-current motors for main-roll drives, and a report of the Sub-Committee on Illumination.

The following new officers were elected: Warren S. Hall, Illinois Steel Co., Chicago, president; R. B. Gerhardt, Bethlehem Steel Co., Sparrows Point, Md., first vice-president; L. F. Galbraith, West Penn Steel Co., Brackenridge, Pa., second vice-president; J. F. Kelly, Pittsburgh, Pa., secretary; and James Farrington, LaBelle Iron Works, Steubenville, Ohio, treasurer.

American Society for Steel Treating

At the third annual convention and exhibition of the American Society for Steel Treating, held at Indianapolis, September 19–24, over 40 papers were presented and discussed, and as many more were presented by title. Research and management were subjects placed on the program of the society for the first time.

Carbonizing was the subject of the first technical session and various processes were discussed by several speakers. Simultaneous sessions on tool steel and heat treatment of special products were held the second day, and included papers on physical tests on high-speed steel, brass forgings, and heat treatment of copper and brass.

On the morning of September 22 two simultaneous sessions were held, one on army and navy subjects, including an illustrated paper on railway gun mounts, and one on alloy steel, at which several papers of interest on the mechanical properties of various alloy steels were presented. In the afternoon another group of sessions covered the subjects of metallographic research and heat-treating equipment.

Research, management and costs, and heat-treating problems were discussed on the last day of the conference.

Of the new officers elected, Frank P. Gilligan, of the Henry Souther Engineering Co., Hartford, Conn. is president; F. C. Lau, Arrow Forging & Tool Works, Chicago, first vice-president; R. J. Allen, Rolls-Royce Co. of America, Springfield, Mass., second vice-president; J. V. Emmons, Cleveland Twist Drill Co., Cleveland, treasurer; and J. J. Crowe, Philadelphia Navy Yard, director.

In conjunction with the meeting of the steel treaters an exhibition was held in which the products of over 60 manufacturers of metallurgical equipment and heat-treating devices were presented.

Argentine National Engineering Congress

The second Argentine National Engineering Congress was held in Buenos Aires, Argentine, S. A., Sept. 23, 1921, under the auspices of the Centro Nacional de Ingenieros. The conference commemorated the centennial of the founding of the University of

ing, transportation, and general.

The hydraulic session included discussion of irrigation by pumping, and drainage systems in Buenos Aires and the interior.

Water supply, purification and transportation of water, and sanitation in unhealthy districts were discussed at the session on sanitary engineering.

One group of papers discussed at the session on industrial engineering dealt with electrotechnical subjects, including electric and hydroelectric plants, distribution of energy, industrial and domestic applications, electric traction, telegraphy and telephony, electric propulsion of ships, and power supply for electrification of suburban railways. Other groups of papers presented at the industrial session were on such subjects as textiles, woods, paper, cement, brick, glass, refrigeration, liquid and pulverized fuel, mining and metallurgy, rural water and power supplies, etc.

Aeronautical, vehicular, and rail transportation were discussed at length at the session of means of communication and the general session included questions of economics and legal engineering.

The invitation to the American National Engineering Societies in Argentina to send delegates to this conference, was a recognition of this organization which was formed early this year as a result of the activities of Local Sections of the A.S.M.E.

American Electrochemical Society

The fortieth general meeting of the American Electrochemical Society was held at Lake Placid, N. Y., Sept. 29, 30 and Oct. 1. The outstanding feature of the technical program was a symposium on non-ferrous metallurgy, at which two papers were presented the Metallurgy of Non-Ferrous Metals, by H. M. St. John, of the Detroit Electric Furnace Co., and Resistance-Type Electric Furnace in the Melting of Brass and other Non-Ferrous Metals by T. F. Baily, of the Electric Furnace Co., Alliance, Ohio. In a paper by N. K. B. Patek, works manager of Lumen Bearing Co., Buffalo, N. Y., electric-furnace practice was compared with fuel-fired-furnace practice. H. A. De Fries, consulting engineer, New York, described an electric silver-melting equipment, and Dr. E. F. Northrup, of the Ajax Electrothermic Corporation, Trenton, N. J., discussed some difficulties met in melting a large quantity of silver. Other papers in the symposium dealt with electric-furnace melting of nickel silver, recent developments in electric furnaces of the muffled-arc type, and modern developments in the British brass industry.

In the general session, a paper on Experiences with Alkaline and Alkaline Earth Metals in Connection with Non-Ferrous Alloys was presented by Charles Vickers, consulting foundry engineer, Buffalo. He stated that sodium was the best of the alkaline metals for use as a deoxidizing agent in making copper castings of superior torsional strength, and that calcium, in combination with an acid element, will produce castings of good electrical conductivity.

The theory that corrosion is started by the formation of colloidal ferrous oxide was discussed in a paper by J. Newton Friend, of Birmingham.

Rust Prevention by Slushing was the title of a paper presented by Haakon Styri, Chief of the S.K.F. Research Laboratory, Philadelphia. This paper emphasized the importance of preventing rust on steel parts which cannot be given a permanent coating of paint or metal.

LIBRARY NOTES AND BOOK REVIEWS

Aeroplane Performance Calculations. By Harris Booth. Dutton & Co., New York, 1921. (The Directly Useful Technical Series.) Cloth, 6 × 9 in., 207 pp., diagrams., $8.

This book, it is hoped, will meet the need of aeronautical engineers and designers for a practical method of calculation; it is in three sections: first, a descriptive and theoretical section explaining the points to be noticed and deriving the necessary formulas; second, an explanation of practical procedure; third, an example of the application of the method described to an actual machine.

Alternating Currents. By Carl Edward Magnusson. Second edition. McGraw-Hill Book Co., Inc., New York, 1921. Cloth, 6 × 9 in., 559 pp., illus., $4.50.

A presentation of the fundamental principles of alternating-current phenomena, with illustrations of their application to industrial problems, intended to aid the student in gaining clear concepts of what actually takes place in alternating-current machinery, to explain the relations between the factors involved and to express the physical facts in mathematical forms in such a manner that he shall understand the equations and be able to use them rationally in the solution of industrial problems.

America's Power Resources. By Chester G. Gilbert and Joseph E. Pogue. The Century Co., New York, 1921. Cloth, 5 × 8 in., 326 pp., illus., $2.50.

An attempt to interpret the importance attaching to the energy resources, coal, oil, natural gas and water power, to point to the shortcomings in the way they are handled, to outline the changes in the administration of energy which are bound to come into play if due social and industrial progress is to be attained, and to indicate the avenues of advance along which constructive efforts should be applied. The material presented is largely the result of investigations by the authors, brought out from time to time as special papers, emanating mostly from the Division of Mineral Technology, United States National Museum, and more popularly presented here in a unified and less technical form.

Automatic Telephony. By Arthur Bessey Smith and Wilson Lee Campbell. Second edition. McGraw-Hill Book Co., Inc., New York, 1921. Cloth, 6 × 9 in., 430 pp., illus., diagrams, $5.

The method adopted is to describe fully the typical circuits and apparatus of the Strowger type, and to outline briefly the other important systems. By this method it has been possible to explain the principles and methods fully enough for their application to other makes of equipment, without attempting to narrate the practice of all manufacturers in detail. This edition is radically changed from the previous one by the elimination of obsolete matter and the introduction of new material.

Electric Furnace. By J. N. Pring. Longmans, Green & Co., New York, 1921. (Monographs on industrial chemistry.) Cloth, 6 × 9 in., 485 pp., plates, illus., $10.50.

Although the most noteworthy branches of the electrochemical and electrometallurgical industries have been described in a number of publications, the present rapid progress of these enterprises demands a frequent revision and extension of the literature. This volume is an additional contribution to the general technical discussion of the position and prospects of high-temperature industrial chemistry. The author reviews the history and principles of the electric furnace and describes the types in use. Current supply, transformers and the measurement of high temperatures are treated and the use of the electric furnace in the metallurgy and chemistry of the important metals is described. Attention is also given to furnace design and to the economic aspects of electrochemical processes. A useful bibliography is appended.

Etude des Mouvements Appliquee. By Frank B. Gilbreth and L. M. Gilbreth. Dunod, Paris, 1921. Paper, 5 × 8 in., 161 pp.

In 1918 Mr. Gilbreth's Motion Study appeared in French. Evidently it attracted interest, for it is now followed by a translation of Applied Motion Study, a collection of papers by Mr. and Mrs. Gilbreth which was published in this country in 1919. The publication of the book is an indication of the keen interest of French engineers and manufacturers in American methods of production.

Grundlagen und Gerate Technischer Langenmessunoen. By G. Berndt and H. Schulz. Julius Springer, Berlin, 1921. Paper, 6 × 10 in., 216 pp. illus., 48 M.

This discussion of the principles upon which our measurements of length rest and the instruments used for measurement is intended for engineers and machinists engaged in manufacturing industries. The book first explains the development of the metric system, the standard meter and the methods of reproducing it. The development of industrial measures and gages is then described fully, their exactness discussed and the physiological errors that occur are explained.

Handbook of Standard Details for Engineers, Draftsmen and Students. By Charles H. Hughes. D. Appleton and Co., New York, 1921. Cloth 5 × 7 in., 312 pp., tables, diagrams, $6.

The book is a compilation, in a volume of convenient size, of drawings, tables and formulas of standard details. Included among these are fastenings of various kinds; shafting, clutches, collars, bearings, gearing and other parts of power transmissions; pipes tubes and fittings; rope and chain fittings; structural and miscellaneous details. Much of the material has been furnished by American machine-tool manufacturers and represents their practice.

Heat Treatment of Soft and Medium Steels. By Federico Giolitti. Translated by E. E. Thum and D. G. Vernaei. First edition. McGraw Hill Book Co., Inc., New York, 1921. Cloth, 6 × 9 in., 374 pp., illus. $5.

Contents: The Phenomena of Diffusion in Primary Solid Solution; Effects of Diffusion upon Secondary Crystallization; Diffusion in Austenite as Applied to Preliminary Heat Treatment of Steels; Preliminary Heat Treatment of Steel Castings; Preliminary Heat Treatment of Forged and Rolled Steels.

Metallurgists and metallographists, according to the translator of this volume, have only recently been impressed by the fact that various impurities and addition agents may affect the properties of finished steel far in excess of that expected by their apparent amount. Precise data along the lines are almost entirely lacking; therefore this book, containing the first systematic discussion of their effect on commercial heat treatment, should prove a stimulus toward their study as it shows the great advantages to be gained by their elimination or suppression.

Heating Systems. By F. W. Raynes. Second edition. Longmans, Green and Co., New York, 1921. Cloth 6 × 9 in., 324 pp., plates, diagrams, tables, $7.50.

This textbook on the design of heating systems presents modern English practice. A special feature is the large number of charts that have been prepared and the method adopted for calculating pipe sizes. The practical rather than the theoretical aspects of the work have been given attention. Consideration is also given to the economical aspect of heating problems, especially in the heating of industrial buildings and plants. The new edition has been brought up to date.

Induction Motor and Other Alternating-Current Motors. By B. A. Behrend. Second edition, revised and enlarged. McGraw-Hill Book Co., Inc., New York, 1921. Cloth, 6 × 9 in., 272 pp., portraits, diagrams, $4.

This work appeared first in 1901 and is based on a series of lectures delivered at the University of Wisconsin during the preceding year. This second edition, twenty years later, has been expanded from 105 to 272 pages and thoroughly revised to represent the author's present opinions on its subject. The book is not meant to be encyclopedic. It is, in the words of the author, "essentially the work of an engineer who has had the good fortune to have been actively associated with the art of electrical engineering through almost three decades and who has had a part in the development of the machines about which he writes."

Traite de Dynamique. By Jean d'Alembert. Gauthier-Villars et Cie, Paris, 1921. (Les maitres de la pensee scientifique.) Paper, 4 × 7 in., 2 vol.

This edition of d'Alembert's work on mechanical philosophy is reprinted from the second edition, which appeared in 1758, and which was enlarged and corrected by the author. It fills the need for an inexpensive, accurate edition of the book.

D'Alembert (1717–1783) was the most prominent student of celestial mechanics between Newton and Laplace. His investigations prepared the way for the Analytical Mechanics of Lagrange.

IMPRESSIONS OF INDUSTRIAL RUSSIA

(Continued from page 751)

man's position was almost unbearably difficult. He was between two fires. On one side was the management committee, made up of a workman from the factory, a former draftsman and an appointee from the central office of the Metal Department. They occupied the elaborately furnished offices of the factory, and gave impractical and impossible orders. The other difficulty was the interference of orders from four automobile departments of the government. The military department gave peremptory orders, saying "Here is an automobile which must be repaired before a certain date or you will be shot."

In addition, the chief engineer was struggling with a thousand untrained, hungry, cold, dejected men; his own family, consisting of wife, two children and a lady relative, were living in two rooms heated by small sheet-iron stoves. He had no automobile and as there was no street-car service he walked to the factory every morning, about 3 or 4 miles. This man went struggling constantly with the personal problem of fuel and food, often dragging supplies home himself on a hand sled. His holidays and evenings were spent in disagreeable, trying physical labor, such as cleaning stoves, sawing and splitting wood, carrying water, etc. On many holidays he went to the factory and joined with labor parties in physical work, removing snow and refuse, and cleaning up the factory.

Education

It is often stated by supporters of the Bolshevik government that while there cannot be very much expected from the present generation of workers trained under capitalistic methods, the generation now being educated will bring about a new industrial day. It is therefore interesting to take a look at this educational system of which they speak.

When one understands the terrible difficulties in the way it is not surprising that there are no results either in education or production. They have quite a beautiful theory of education for all. However, with four years of destruction and no printing except Bolshevik propaganda, there are no schoolbooks and no educational literature. Magazines and books of general educational value are almost entirely lacking. In addition to this, there is not sufficient fuel to heat the school buildings. There is a shortage of teachers, and such simple things as notebooks, slates, lead pencils, pens, ink, etc. are very scarce or entirely lacking.

The universities are open to every one. This makes it extremely difficult for the professors, who try to suit their lectures to the average student body, with the result that they are commonplace for those with preparatory training and unintelligible to the unprepared.

The children are always cold and hungry. There is no adequate provision for taking care of the schoolrooms and keeping them heated and clean, and the students are required to prepare the fuel and clean the buildings.

The main inducement to attend the schools is a noon lunch of a little soup made from cabbage or dried fish, with sometimes a little black bread.

Bolshevik Leaders Hide Economic Failure

The Bolsheviki have been successful in diverting public attention from their economic failure. First they ascribed it to the war and blockade. Following this they lulled the people with much talk of concessions by which they hoped to lure the capitalists of the world into their country and use them as a tool for solving the very difficult situation. The next cry was that of electrification, there were wonderful schemes for electrifying the entire Russian country and an electric train made a trip from Petrograd to Moscow. This was an ordinary storage-battery train, which is, of course, impractical for such service. The latest diversion is feeding the starving. There is no doubt that entire Russia is in danger of starvation, but the Bolsheviki attempt to make it appear that the cause is entirely due to the crop failure. It is true that there has been a crop failure in the lower Volga grain-producing section. In normal times, however, Russia exported large quantities of grain, and had there been a reserve and adequate transport, Russia could have taken care of its population.

It is almost useless to speculate on what the result will be. But everybody, even the Bolshevik leaders themselves, apparently has come to the conclusion that this gigantic centralized organization scheme cannot succeed. Therefore there is the effort to decentralize and denationalize. Small private business is now permitted and there is much talk of the coming decrees which will give back to the former owners their houses and the smaller factories. But it is difficult to understand how they can be given back to private ownership. First the factory organizations have been destroyed, the stock of raw material and products consumed, and the buildings and equipment are in bad repair. To add to the difficulty of the private owner is the lack of financial machinery which he must have to do business. Lastly, all the liquid wealth of Russia has been destroyed.

In general, there seem to be only two suggested solutions for the present difficulty. One is the violent overthrow of the present government, but this seems impossible with opposition party leaders in jail and their followers under constant surveillance. The other is evolution to capitalistic private ownership. With all the talk of concessions I know of not one single effective concession which has been given. It seems almost impossible to establish a basis on which a concession could be given that would be acceptable to an outside capitalist. It also seems equally impossible to think of a plan by which the Bolshevik and capitalistic ideas can be mixed. Therefore the future of Russian industries is not bright. When reconstruction begins, manufactured products must be bought from the outside for the next one or two generations. Russia will be indeed fortunate if she can take care of her own repair and maintenance.

MAKING WORK FASCINATING AS FIRST STEP TOWARD REDUCING WASTE

(Continued from page 734)

rate of wage based on *time and class* of work and a *secondary* rate of wage based on actual *exercise of skill*, knowledge and intelligence.

A method of compensation of this character stimulates the development and exercise of creative power, encourages elimination of waste and does not suppress the desire to serve. In seeking these aims the fascination is readily found, while the interest in improvements and accomplishments is not pushed to the background by financial uncertainties or worries.

Another notable attempt to combat the evils arising from the lack of interest provided by mechanized work, may be observed in the hopes aroused by certain claims that a careful selection of workers to fit the work will eliminate dissatisfaction created by the poor fitting of men to jobs. These hopes wane as rapidly as they spring into prominence because the selection of men for jobs is an error of lowering a dimension. The correct course would be to fit the jobs to the men—in other words, to elevate the work to human dimensions, requiring not mere physical or animal power but an exercise of creative, intelligent faculties as well. The first step along this road is training the worker,[1] as opposed to securing unambitious, discouraged ones of low intelligence and further degrading them by assigning them to perform the lower functions of beasts of burden.

The next step advocated is to organize the work so that the worker's intelligence and his creative or imitative instincts will be brought into play. This requires (I) analysis of jobs and processes to bring out the interrelation of causes and effects and (2) the education of operators in conscious control of these forces and relations so that they can at will influence the results.

In order to eliminate a major part of our industrial losses, the creative, intelligent impulses of men should be given the fullest opportunity of self-expression. As an ideal we may foresee a complete abolition of monotonous, automatic, repetitive operations performed by men. These should be relegated to machines, while men should assume the part of directors and supervisors of processes. Workers by brain and by hand should unite in inducing relations between causes and effects, which are separated by the time elapsed. *Our imperfect machines, inefficient methods, wasteful processes and monotonous operations are the results of the incomplete, restricted use of our creative capacities.*

[1] Training Workmen, etc., H. L. Gantt.

It is now generally recognized in industry that idle equipment is harmful; the greatest source of waste is to be found in the idleness of our available knowledge and creative capacities of men, which are not liberated and applied productively under the mechanistic, formal organization.

The greatness of a new industrial leader will lie in his ability to liberate the creative forces within men, as against relegating them to the level of animals carrying burden and doing machine-like work.

In the author's experience in promoting and increasing industrial efficiency, he has found that the most fundamental, most successful and most enduring way to do it is in the elevation of man to his true dignity as an intelligent, creative agent. To be specific, the monotonous physical labor of a fireman is readily transfigured by special training into a fascinating game based on the exact sciences of physics and chemistry, requiring an exercise of mental capacities. Watching and interpreting a simple array of instruments (Fig. 3) provides men with interest, which is augmented as they intelligently control a process and watch the results attained.[1]

Charting the progress made in elimination of waste of material provides further source of satisfaction in observing one's own improvement in the mastery of processes through the acquisition of knowledge and skill. These charts (Figs. 4, 5, 6 and 7) are plotted on the basis of what is possible of accomplishment with a proper exercise of intelligence, knowledge, and skill, and the short bars indicate the falling short of possibility. Sometimes it is found that a playful spirit of friendly competition or just pride in self-improvement and accomplishment prompts men to draw similar records on the fronts of their boilers (Fig. 8) or elsewhere in the room. When men find themselves thinking about their job it loses its monotony. Moreover, the amount of physical labor is reduced in some inverse proportion to the intelligence applied.[2]

Similar reorganization of jobs and corresponding transformation of workers' attitude have been successfully tried in a variety of establishments—in the glass industry,[3] pulp and paper mills,[4] foundries, power plants,[5] etc.— and the further application of these principles awaits the progressive coöperation of manufacturers and industrial leaders.

---

[1] "The object should surely be to make the workman in the future more of a director of instruments than a laborer, and to unite hand and brain as of necessity implying each other." Viscount Haldane of Cloan in introduction to Lord Leverhulme's Six Hour Day, Henry Holt & Co., N. Y., 1919.

[2] In such purely physical work as passing coal and ashes in power houses, this "bringing mind into labor" reduces amount of manual labor often to one half of former. In many cases work was considered so hard that labor turnover exceeded 300–500 per cent; the personnel remained on payroll unchanged for years after these principles were brought into play.

[3] In a glass and mirror factory the writer was able within a few months to develop such interest in the work that in a strictly unionized shop, the men in roughing department increased production 100 per cent and reduced expenses 34 per cent; in emery department the increase was 125 per cent and in surface polishing department 150 per cent with corresponding economies in production despite the fact that men's earnings at the same time increased by payment of 25 per cent bonus; amount of defective work was also reduced to one-fifth of the former.

[4] "This sort of creative efforts produced great changes in operating conditions." R. Wolf tells that in a pulp mill "we increased our yearly production from 42,000 tons to 111,000 tons without adding to the number of digesters for cooking the pulp, or wet machines for handling the finished product and we changed our quality from the poorest to the very best."

[5] In a typical power house of a large and progressive manufacturing concern, application of the writer's principles produced results thus reported by general superintendent to the president: "When the fact is taken into consideration that in the early part of 1918 we were paying $3.98 per ton delivered for coal, and that today our contract calls for a price of $5.15—and the market price of power-house labor has increased slightly more than 50 per cent,. . .our unit cost of power has gradually been reduced from a high cost of 1.11 in 1918 to an average less than 0.5, it can be seen that the improvement has been marked." In another instance the new spirit created was reflected in the report of an officer of the company stating that: "Not only have the results of the introduction of the new practice been most gratifying from the standpoint of reduction of expenses to the company and improvement in the conditions affecting the workman and his compensation, but it has also increased the mutual respect between management and workman and has developed the ésprit de corps which is so beneficial to both. The workman is as much interested in the success of the methods which have been established as is the management." J. C. Scholl, Pennsylvania Electric Association, 1915.

THE ENGINEERING INDEX

(Registered U. S. Patent Office and Canadian Patent Office.)

THE ENGINEERING INDEX presents each month, in conveniently classified form, items descriptive of the articles appearing in the current issues of the world's engineering and scientific press of particular interest to mechanical engineers. At the end of the year the monthly installments are combined along with items dealing with civil, electrical, mining and other branches of engineering, and published in book form, this annual volume having regularly appeared since 1906. In the preparation of the Index by the engineering staff of The American Society of Mechanical Engineers some 1200 technical publications received by the Engineering Societies Library (New York) are regularly reviewed, thus bringing the great resources of that library to the entire engineering profession.

Photostatic copies (white printing on a black background) of any of the articles listed in the Index may be obtained at a price of 25 cents per page, plus postage. A separate print is required for each page of the larger periodicals, but wherever possible two small or medium-sized pages will be photographed together on the same print. The bill will be mailed with the print. When ordering photostats identify the article by quoting from the Index item: (1) Title of article; (2) Name of periodical in which it appeared; (3) Volume, number, and date of publication of periodical; (4) Page numbers. Orders should be sent to the Engineering Societies Library, 29 West 39th Street, New York.

ACCIDENTS

Industrial. Accidents in Factories and Workshops. Chem. Age, vol. 5, no. 112, August 6, 1921, pp. 156–158. Notes on dangers in machinery and processes from annual report of British chief factory inspector.

Reduction of Waste Through Accident Prevention, L. A. DeBlois. Chem. & Metallurgical Eng., vol. 25, no. 9, Aug. 31, 1921, pp. 403–406, 1 fig. Points out importance of careful analysis of industrial accidents in chemical industry.

AERIAL BOMBARDMENT

Course-Setting Bomb Sight. A Course-setting Bomb Sight. Engineer, vol. 132, no. 3425, Aug. 19, 1921, pp. 186–187, 5 figs. Describes latest type of bomb sight, invented by H. E. Wimperis, which permits attack to be delivered at any angle to the wind.

AERODYNAMICS

Stability. Graphic Investigation of Transverse and Lateral Stability (Untersuchung der Querstabilität und Seitenstabilität auf graphischem Weg), A. Baumann. Zeit. für Flugtechnik u. Motorluftschiffahrt, vol. 12, no. 14, July 30, 1921, pp. 212–220, 7 figs. Graphic method of investigation is developed based on numerical calculations of Reissner, Gehlen, and others. Importance of graphic investigation for soaring flight.

AEROPLANE ENGINES

Fuel Systems. The K L Fuel System. Aerial Age Wkly., vol. 13, no. 22, August 8, 1921, pp. 515–516, 7 figs. Designed to overcome troublesome features common in complex systems now in use and to completely meet the exacting requirements of aeroplane work.

AEROPLANE PROPELLERS

Air Moved by. Approximate Determination of the Quantity of Air Put in Motion by a Propeller Blade (Détermination Approximative de la Masse d'air que met en Mouvement une Aile d'hélice), Drzewiecki. L'Aerophile, vol. 29, no. 11–12, June 1–15, 1921, pp. 170–173, 3 figs.

AEROPLANES

Aerofoils. The Variation of Aerofoil Lift and Drag Coefficients With Changes in Size and Speed, Walter S. Diehl. Aerial Age Wkly., vol. 13, no. 22, August 8, 1921, pp. 518–520, 8 figs. General statement of principle of dynamic similarity as applied to the problem of determining variation of lift and drag of an aerofoil with size and speed.

Berline Spad. The Berline Spad-Herbemont S 33 (La Berline Spad-Herbemont S 33), E.-H. Lémonon. L'Aerophile, vol. 29, no. 11–12, June 1–15, 1921, pp. 167–169, 2 figs. A new type of six-seater aeroplane fitted with Salmson 250-hp. engine.

Bracing, Internal. The Internal Bracing of Aeroplane Wings, A. H. Stuart. Engineering, vol. 112, no. 2904, Aug. 26, 1921, pp. 301–302, 5 figs. Results of experiments for obtaining suitable data regarding initial tension to be put upon internal bracing wires of wings.

Rieseler. The New Rieseler Sport Monoplane (Das neue kleine Rieseler-Sportflugzeug), E. Meyer. Motorwagen, vol. 24, no. 20, July 20, 1921, pp. 411–414, 4 figs. Characteristics: Span, 7 m.; total length, 5.8 m.; weight empty, 150 kg.; engine, 30-hp. Haacke; speed, 110 km. per hr. Discusses requirements of a sport aeroplane.

Soaring Machine. The Construction of the Soaring Machine of the Baden-Baden Soaring Aeroplane Works, Ltd. (Bauart der Segelflugzeugwerke G.m.b.H. Baden-Baden), F. Wenk. Zeit. für Flugtechnik u. Motorluftschiffahrt, vol. 12, no. 14, July 30, 1921, pp. 211–212, 3 figs. Machine is a monoplane with strut and ordinary profile, but with large aspect ration and small surface load. Design is based on achievement of a high inherent stability.

10-Seater Tractor Biplane. Single-Engined Ten-Seater Tractor Biplane. Engineer, vol. 132, no. 3420, July 15, 1921, p. 73, 1 fig. Built by Bristol Aeroplane Co., Ltd., Bristol, England. Span, 54 ft.; length overall, 42, ft.; height, 11 ft.; speed at ground level, 122 mi. per hr.; ceiling, 13,500 ft.

Truss Ribs. Experimental Reinforced Plywood Truss Ribs. Air Service Information Circular, vol. 3, no. 212, April 30, 1921, 17 pp., 17 figs. Description of tests and recommendations.

AIR COMPRESSORS

Explosions. What Causes Explosions in Air Compressors? A. D. Risteen. Can. Machy., vol. 26, no. 6, August 11, 1921, pp. 35–36. Discusses carbonization of oil, ignition of carbon and removal of carbon and oil deposits.

German Types. Compressors (Kompressoren). Schiffbau, vol. 22, no. 42, July 20, 1921, pp. 1040–1043, 5 figs. Notes on Koster's valve gear, single-stage compressors; single-cylinder stage compressor for suction pipes up to 2000 cu.m. output per hr.; tandem compound compressors for suction pipes from 2500 to 5000 output per hr.; and high-speed compressors, built by Frankfort Machine Constr. Corp., Germany.

High-Pressure. A New Design of High-Pressure Compressors. Practical Engr., vol. 64, no. 1795, July 21, 1921, pp. 40–41, 5 figs. Describes Reavell "Axial" single-stage air compressor.

Lubrication. Avoiding Compressor Troubles, A. D. Risteen. Iron Trade Rev., vol. 69, no. 8, Aug. 25, 1921, pp. 489–492 and 495. Lubrication is said to be factor, and oil must have suitable properties. Explosions of external and internal origin can be prevented by cleaning accumulations periodically. Compressors usually over-lubricated.

Reavell Quadruplex. The Reavell Quadruplex Air Compressor and Some Tests Thereon. Engineer, vol. 132, no. 3421, July 22, 1921, pp. 98–100, 9 figs. Report of tests made by H. Riall Sankey on 1920 design.

AIRSHIPS

Inflation. Chart for Inflating Airships (Diagramma dei Lavaggi delle Aereonavi), Angelo Varoli-Piazza Revista Marittima, vol. 54, no. 6, July 1921, pp. 751–756, 2 figs. Discusses two ways of adding daily a certain quantity of gas and charging completely.

PL 27. The PL 27 Dirigible (Das Luftschiff PL 27). Motorwagen, vol. 24, no. 22, Aug. 10, 1921, pp. 455–460, 7 figs. Built in 1916 by the Aircraft Co. in Bitterfeld, Germany. Specifications: Max. length, 157 m.; diam. 19.6 m.; height, 26.5 m; max. circumference, 61.55 m.; volume, 31,300 cu. m.; useful lift, 18,000 kg.; speed, 27.3 m. per sec. Each nacelle is equipped with a 240-hp. Mayhach engine.

ALLOY STEELS

Electric. Three Types of Alloy Sheet Steel—I, Horace C. Kneer. Iron Age, vol. 108, no. 10, Sept. 8, 1921, pp. 594–596, 2 figs. Deals with investigation of three commercial types of high-strength alloy steel in sheet form, carried out at Naval Aircraft Factory, Philadelphia, to determine which was most suitable for manufacture of fittings for large aircraft.

ALUMINUM

Welding. Oxy-Acetylene Welding Cast and Sheet Aluminum. Can. Machy., vol. 26, no. 4, July 28, 1921, pp. 31–32 and 35. Describes various operations involved.

ALUMINUM ALLOYS

See DURALUMIN.

ASH HANDLING

Methods. The Removal of Ashes in Large Boiler Houses (Ueber die Aschenbeseitigung in grossen Kesselhäusern), Ph. Scholtes. Elektrische Kraftbetriebe u. Bahnen, vol. 19, no. 11, June 10, 1921, pp. 129–133, 9 figs. Account of special meeting of the Bavarian Electrical Works Engineers for study of ash-removal methods. Experiences and costs in different plants with various systems.

Plants. Modern Ash- and Slag-Removal Plants in Boiler Rooms in Rhenish-Westphalian Mines (Neuzeitliche Entaschungs- und Entschlackungsanlagen in Kesselhäusern auf rheinisch-westfälischen Zechen), M. Schimpf. Glückauf, vol. 57, no. 32, Aug. 6, 1921, pp. 761–765, 8 figs. Describes various systems in use.

Railroad Ash-Handling Plant Has Buckets and Crane. Eng. News-Rec., vol. 87, no. 8, Aug. 25, 1921, p. 310, 2 figs. Installation on Burlington railroad designed for economical and direct handling from pits to cars.

Pneumatic Removal of Flue Dust (Pneumatische Flugaschenförderung), F. Ohlmüller. Zeit. fur Dampfkessel u. Maschinenbetrieb, vol. 44, no. 3, Jan. 21, 1921, pp. 17–21, 8 figs. Describes a portable ash-removal pump of the Siemens-Schuckert Works with portable vacuum-proof collector in form of a lorry.

AUTOMOBILE ENGINES

Ignition Advance. An Analysis of the Automatic Ignition Advance Mechanism, C. H. Hindl. Automotive Ind., vol. 45, no. 7, August 18, 1921, pp. 312–314, 3 figs. Description and calculation.

Intake Manifolding. Intake Manifolding. Motor Age, vol. 40, no. 7, August 18, 1921, pp. 14–15, 13 figs. Multi-cylinder manifolding as applied to six-cylinder engines.

Lapping Machines for Bearings. Lapping and Running-in Machine, A. B. Bassoff. Machy. (N. Y.), vol. 28, no. 1, Sept. 1921, pp. 5–7, 4 figs. Function of lapping machine. Design of oscillating and of reciprocating mechanism. Types of work lapped.

Starters. Electric Starting Systems for Automobiles (Los Sistemas Eléctricos de Arranque Para Automóviles), F C. Barton. Boletín de la Asociación Argentina de Electrotécnicos, vol. 7, No. 2, January-

bath. (To be concluded.)

Machining Auto Starter Frames, Robert Mawson. Am. Mach., vol. 55, no. 8, Aug. 25, 1921, pp. 296–298, 15 figs. Practice at plant of Gray & Davis, Inc., Boston, Mass. Special fixtures for drilling and tapping; devices for locating and removing work; boring fixture for polepieces.

AUTOMOBILE FUELS

Exhaust-Gas Odors. Street Hygiene and Automobile Exhaust Gases (Strassenhygiene und Automobilauspuff), Georg Wolff. Gesundheits-Ingenieur, vol. 44, no. 23, June 4, 1921, pp. 271–274. Discusses means of rendering exhaust gases as odorless as possible. Deals with properties of principal automobile fuels—gasoline, benzol (C_6H_6), and benzol and alcohol mixtures—and with lubricating oils.

AUTOMOBILES

A.B.C. The A.B.C. 12 H.P. Light Car. Auto, vol. 26, no. 29, July 21, 1921, pp. 621–625, 9 figs. Made by A.B.C. Motors, Ltd., Walton-on-Thames, Surrey. General description of engine, valve gear, clutch, gearbox, etc.

Daimler. A New Daimler. Autocar, vol. 47, no. 1345, July 30, 1921, pp. 205–207, 8 figs. Describes a 20-hp. 4-cylinder model embodying original details of design.

Durant. Technical Features of New Durant Car, P. M. Heldt. Automotive Ind., vol. 45, no. 7, August 18, 1921, pp. 306–308, 6 figs. Engine is of an overhead valve type and cylinders and top half of crankcase are in single castings.

Generator Armatures. Production Methods in Armature Manufacture, Norman G. Shidle. Automotive Ind., vol. 45, no. 7, August 18, 1921, pp. 318–320, 6 figs. Describes generator armature made by Western Electric Company, Springfield.

Grand Prix, 1921. Prize Competition of the Automobile Club of France (Le Grand-Prix de l'Automobile-Club de France en 1921). Le Génie Civil, vol. 79, no. 6, August 6, 1921, pp. 121–124, 7 figs. Data on the course, and motors and motorcycles competing.

Headlights. Motor Car Headlights: Ideal Requirements and Practical Solutions, A. Garrard. Illuminating Engr., vol. 14, no. 4, April 1921, pp. 92–102 and (discussion) pp. 102–107, 5 figs. Discusses effect of dazzling light on eyes and defines in general terms desirable characteristics of a non-dazzle headlight.

Pilain. The 12-HP. S.L.I.M. (Pilain) (La voiture 12 HP. S.L.I.M. (Pilain)), A. Contet. La Vie Automobile, vol. 17, no. 735, August 10, 1921, pp. 279–283, 10 figs. Details of construction of automobile, a new model by the Société lyonnaise d'industrie mécanique.

Schneider. The 16–20 HP. Schneider. Auto, vol. 26, no. 32, August 11, 1921, pp. 687–690, 9 figs. A French 4-cylinder car, produced by Th. Schneider, Besançon.

Shock Absorption. The Shock Absorption of Automobiles (Bemerkungen zur Abfederung der Motorwagen), H. Reissner. Motorwagen, vol. 24, no. 17, June 20, 1921, pp. 339–343, 5 figs. Based on given calculations, writer seeks to show that light cars do not necessarily sustain greater injury or run less smoothly on poor roads than heavy cars, providing the springs are sufficiently flexible and properly placed.

Spyker. The New Six-Cylinder 30/40-HP. Spyker Automobile (Der neue Sechzylinder 30/40 PS-Spyker-Wagen). Motorwagen, vol. 24, no. 22, Aug. 10, 1921, pp. 453–455, 4 figs. Specifications of car built by The Netherlands Automobile and Aeroplane Factory Trompenburg, Amsterdam: Length of body, 2.84 m.; width, 1.04 m.; wheelbase, 3.47 m.; engine, Maybach with 95-mm. bore and 135 mm. stroke.

Transmission Gears. Machining the Wrigley Automobile Transmission Gear—III, I. William Chubb. Am. Mach., vol. 55, no. 9, Sept. 1, 1921, pp. 333–338, 21 figs. Machining operations of gear frame and axle parts. Assembling gear frame. Methods of checking up different parts.

AVIATION

Aeronautic Roads. Aeronautic Roads, Story B. Ladd. Aerial Age Wkly., vol. 13, no. 24, August 22, 1921, pp. 563–564, 5 figs. Discusses question of road signs and explains block system illustrated by a map of U. S.

Civil. Aviation and Transport, F. H. Sykes. Jl. Inst. of Transport, vol. 2, no. 5, March 1921, pp. 208–216 and (discussion) pp. 216–218. Discusses military and commercial importance of developing civil aviation.

High-Altitude Aircraft. The High-Altitude Aircraft of the Future (Das Höhenflugzeug der Zukunft), C. Eberhardt. Motorwagen, vol. 24, no. 20, July 20, 1921, pp. 405–408, 3 figs. Points out chief differences in use of dirigibles and giant aeroplanes for long-distance voyages, and maintains that for long trips only the dirigible is capable of traveling the shortest route without stop.

[See also FLIGHT.]

B

BALANCING

Principles. Four Years of Balancing Practice, N. W. Akimoff. Eng. & Ind. Management, vol. 6, no. 5, August 4, 1921, pp. 116–118, 4 figs. Describes principles of static and dynamic balance.

Hawkesworth. U. S. Naval Inst. Proc., vol. 47, no. 222, August 1921, pp. 1233–1249. Discusses the five points: (1) Corrections of gravity for latitude, (2) curvature of earth, (3) westerly drift of projectile, (4) drift toward equator and (5) alteration in projectile's weight.

BALLOONING

Transatlantic. Historical Study of Attempts to Cross the Atlantic in a Balloon (Étude Historique sur les Projets de Traversée de l'Atlantique en Ballon), Charles Dollfus. L'Aeronautique, vol. 1, no. 9, February 1920, pp. 380–386, 9 figs. Describes attempts of Green, Zeise, Lowe, Wise and Donaldson, Godard, Suchard, Wellman, etc.

BEAMS

Reinforced-Concrete. Reinforced-concrete Beams —III, T. C. Broom. Mech. Wld., vol. 52, no. 1805, August 5, 1921, pp. 108, 1 fig. Discusses chart for concrete T-beam with single reinforcement. (Concluded.)

Unsymmetrical Sections. Calculating the Strength of Unsymmetrical Sections. Machinery (Lond.), vol. 18, no. 463, August 11, 1921, pp. 575–577, 2 figs. Two methods of determining moment of inertia, together with formulas for obtaining section modulus and radius of gyration.

BEARINGS

Spherical. Boring Spherical Bearing Housing, J. Blakey and J. Shankey. Mech. Wld., vol. 52, no. 1805, August 5, 1921, pp. 98, 2 figs. Describes economical method of boring spherical bearing housing for shaft connection between gear box and differential gear of heavy motor transport.

BEARINGS, BALL

Friction. The Ball Bearing: In the Making, Under Test, and On Service, Henry L. Heathcote. Mech. Wld., vol. 70, nos. 1804 and 1807, July 29 and Aug. 19, 1921, pp. 79–81, 4 figs., and 140–141, 2 figs. Discusses questions of friction due to slip, position of non-slip bands, internal stresses due to alternating load. Friction and heat at contact surfaces of ball and race ways of a thrust washer. Paper before Instn. Automobile Engrs. (To be continued.)

BENDING MACHINES

Plate. Plate-Bending Machines (Abkantmaschinen). Schiffbau, vol. 22, no. 41, July 13, 1921, pp. 1000–1001, 6 figs. Details of hand-operated and power-operated machines constructed by L. Schuler Machine Works, Göppingen, Germany, for shaping plates.

BENZOL

Recovery. Present and Future of the Gas Industry. Benzol Recovery (L'Etat Actuel et l'Avenir de l'Industrie Gaziere. La Recuperation du Benzol), A. Grebel. Bulletin de la Societe d'Encouragement pour l'Industrie Nationale, vol. 133, no. 6, June 1921, pp. 602–638, 12 figs. Discusses distillation of coal, and production of by-products, and especially recovery and treatment of benzol.

BLAST FURNACES

Charging Installations. Blast-Furnace Charging Installations (Ueber Hochofenbegichtungsanlagen) Stahl u. Eisen, vol. 41, nos. 28, 29 and 31, July 14, 21 and Aug. 4, 1921, pp. 945–954, 994–999 and 1064–1071, 28 figs. July 14: Practice at the Rhenish Steel Works, Duisburg-Meiderich, by H. Lent July 21: Practice of the Bochum Assn., Bochum. Aug. 4: Blast-furnace department of the Gelsenkirchen Min. Corp. Gelsenkirchen. Report of the blast furnace committee of the Assn. German Iron-Metallurgical Engrs.

Improvement Possibilities. Secure Place of the Iron Blast Furnace, Joseph F. Shagden. Iron Age, vol. 108, no. 8, Aug. 25, 1921, pp. 465–467, 2 figs. Features of superiority not met by processes aiming at producing steel direct from ore. Several possibilities of improvements.

Rating Capacities. Rating Blast Furnace Capacities Charles R. Peebles and R. H. Sweetser. Iron Trade Rev., vol. 69, no. 7, Aug. 18, 1921, pp. 430–432. Southern Ohio Pig Iron and Coke Assn. concludes that furnace should burn 60 lb. of coke in 24 hr. for each cubic foot of working volume. Actual stack data is said to verify this figure.

BLOWERS

Gas-Engine-Driven. Gas Engines and Blowers (Les Moteurs a Gaz et Machines Soufflantes de Grande Puissance, Système Galloway). Le Génie Civil, vol. 79, no. 7, August 13, 1921, pp. 141 145, 11 figs. Discusses the Galloway type of engine (1330 hp.) and blower as applied in metallurgical works.

BOILER EXPLOSIONS

Hydraulic Tests as Safeguard. The Value of Hydraulic Tests as a Safeguard Against Explosions. C. E. Stromeyer. Eng. & Indus. Management, vol. 6, no. 7, Aug. 18, 1921, pp. 170–173. (Abstract.) Annual memorandum of Manchester Steam Users' Assn. Analysis of all reported boiler explosions and conclusions therefrom.

BOILER FEEDWATER

Distilled. Economical Production of Distilled Feedwater for Power Station Boilers (Production économique de l'eau distillée pour l'alimentation des chaudières dans les centrales thermiques), M. Lebard. Chaleur et Industrie, vol. 2, no. 15, July 1921, pp. 402–404 and (discussion) pp. 405. Describes system specially studied. Discusses first cost and saving effected.

Regulators. Scientific Boiler Feed Water Regulation.

30–33, 6 figs. Discusses operation of boiler-feed regulators and their adaptation to demand for steam.

Water Levels and Boiler-Feed Regulators (Neuere Wasserstände und Wasserstandsregler für Dampfkessel), M. Kuhlmann. Glückauf, vol. 57, no. 25, June 18, 1921, pp. 581–584, 7 figs. Describes and recommends use of recently devised water gage located nearer boiler-room flow; improved water-level indicator and feed regulator.

Treatment. Modern Arrangements for the Preparation of Boiler Feedwater (Neuzeitliche Einrichtungen zur Erzeugung von Kesselspeisewasser), R. Klein. Zeit. für Dampfkessel u. Maschinenbetried, vol. 44, nos. 4, 5, 6, 7 and 8, Jan. 28, Feb. 4, 11, 18, and 25, 1921, pp. 25–28, 34–37, 41–43, 51–54 and 57–61, 59 figs. Notes on evaporation process and evaporating plant with vapor compressor; exhaust-heat and cooling-water evaporators; purification process with plate boilers; the thermal-chemical purification process; formation of rust through gaseous feedwater; cold and warm distillation; gas protection.

BOILER FIRING

Draft Systems. Natural v. Mechanical Draught for Boiler Plants—1, J. W. Rogers. Mech. Wld., vol. 70, no. 1804, July 29, 1920, pp. 81–82. Discusses natural-draft, induced-draft and forced-draft systems (To be continued.)

Oil-Fired Boilers. Oil Fuel for Boilers Viewed as a Permanent Institution. Mech. Wld., vol. 52, no. 1806, August 12, 1921, pp. 125–126, 3 figs. Discusses salient features necessary for success of oil-fuel application.

BOILER OPERATION

Control. Boiler Control and Apparatus Therefor (Le Contrôle de la Chauffe. Les Appareils de Mesure Servant a ce Contrôle), Paul Frion. Bulletin de la Societe d'Encouragement pour l'Industrie Nationale, vol. 133, no. 6, June 1921, pp. 553–575. Discusses heat balances and various measuring devices to make best possible use of fuel.

Steam-Jet Draft. Calculating a Steam Jet for the Draft of a Boiler (Calcul d'Une Trompe a Vapeur Pour Tirage de Foyer de Générateur, G. Rollet. Arts et Metiers, vol. 74, no. 7, April 1921, pp. 107–113, 6 figs. Explains principle and shows how to calculate maximum efficiency.

Steam Raising. Steam Raising, David Wilson. Elec. Rev., (Lond.), vol. 89, no. 2280, August 5, 1921, pp. 195–196. Discusses efficiency, liquid fuel, air heaters, etc. (Abstract.) Paper read before Incorporated Mun. Elec. Assn.

BOILERS

Corrosion. The Carbon Dioxide Steam as Cause of Corrosion in Steam Power Engines (Kohlensäure des Dampfes als Ursache der in den Dampfkraftmaschinen auftretenden Korrosionen), Ch. Chorower. Zeit. für Dampfkessel u. Maschinenbetrieb, vol. 44, no. 7, Feb. 18, 1921, pp. 49–50. Methods for determining CO_2 content in steam and means of preventing corrosion therefrom.

Electrically Heated. Electric Steam Generators Automatically Controlled (Générateurs Électriques de Vapeur a Régulateur Automatique de Production), J. Besson-Grange. Arts et Metiers, vol. 74, no. 7, April 1921, pp. 114–116, 3 figs. Description of an electric boiler.

BOILERS, WATER-TUBE

High-Capacity. Tests with High-Capacity Boiler-Tube Nests (Versuche mit Hochleistungs-Wasserrohrbündeln), F. Ebel. Glückauf, vol. 57, no. 29, July 16, 1921, pp. 681–687. Discusses increasing of boiler surface by means of boiler-tube nest. Results of numerous tests and conclusions therefrom.

BRASS

Season Cracking. The Season-Cracking of Brass and Other Copper Alloys, H. Moore, S. Beckinsale and Clarice E. Mallison. Engineering, vol. 112, nos. 2903 and 2904, Aug. 19 and 26, 1921, pp. 297–299 and 327–331, 17 figs. Effects of corrosive and other substances on stressed brass. Action of mercury and ammonia on brass and use of mercury for detection of stress. Influence of composition of copper alloys on season-cracking. (Concluded.) (Abstract.) Paper read before Inst. Metals.

BROACHES

Design. Practical Design of Broaches, C. S. Pettit. Machinery, (Lond.), vol. 18, no. 462, August 4, 1921, pp. 538–541, 5 figs.

Theoretical Design of Broaches, C. S. Pettit. Machinery, (Lond.), vol. 18, no. 464, August 18, 1921, pp. 602–603, 3 figs. Discusses construction of a broach tooth.

BUCKET ELEVATORS

Improvements. New Types of Bucket Elevator Unloaders for Handling Coal (Neue Anwendungsformen des Becherwerkentladers für Kohlengutförderung), Hubert Hermanns. Zeit. fur Dampfkessel u. Maschinenbetrieb, vol. 44, no. 21, May 27, 1921, pp. 161–163, 9 figs. Details of recent developments by Heinzelmann & Sparmberg, Hannover, Germany.

BUILDING CONSTRUCTION

Structural Design. Special Structural Design for Newspaper Building. Eng. News-Rec., vol. 87, no. 10, Sept. 8, 1921, p. 412, 1 fig. Lower chord of steel roof trusses will form future floor reinforcement. Units loads varied on floors. Other details of new reinforced-concrete building for South Bend Tribune.

Wood Construction. Modern Wood Construction Methods (Ueber moderne Holzbauweisen), Hugo

Ritter. Schweizerische Bauzeitung, vol. 78, nos. 5 and 6, July 30 and Aug. 6, 1921, pp. 53–56 and 66–69, 14 figs. Describes various systems and discusses fundamental ideas on which different methods are based.

C

CABLEWAYS

Tension Device. The Tensions in Cableways and Chain-Ropeways with Several Driving Sheaves and Their Regulation by Means of the Ohnesorge Compensator (Die Zugspannungen an Seil- und Kettenbahnen mit mehrern Treibrillen und ihre Reglung durch den Ausgleicher von Ohnesorge), R. Goetze. Glückauf, vol. 57, no. 17, Apr. 23, 1921, pp. 385–391, 16 figs. Construction and operation of the Ohnesorge tension compensator.

CALORIMETERS

Testing Liquid Fuels. The Calorimetry of Liquid Fuel. Eng. & Indus. Management, vol. 6, no. 4, July 28, 1921, pp. 95–96, 1 fig. Results of tests with the Sarco calorimeter constructed on Mahler-Donkin bomb system.

CANVAS

Water Resistance of. The Water Resistance of Treated Canvas during Continuous Exposure to Weather, F. P. Veitch and T. D. Jarrell. Jl. Ind. & Eng. Chem., vol. 13, no. 8, August 1921, pp. 672–676, 2 figs. Results of experiments with 12 oz. U. S. Standard army gray duck.

CAR LIGHTING

Electric. Electric Train Lighting By a Three-Brush Dynamo (Éclairage Electrique des Trains par la Dynamo a Trois Balai), S. Iglesis. Arts et Métiers, vol. 74, no. 7, April 1921, pp. 117–125, 17 figs. Describes Stone-Lilliput and Leitner systems.

CARBURETORS

Asmo. The Asmo Carburetor (Der Asmo-Vergaser), C. Wirsum. Motorwagen, vol. 24, no. 17, June 20, 1921, pp. 346–349, 9 figs. Carburetor invented by Gustav Erikson, Upsala, Sweden, draws up fuel automatically from a lower tank, thereby eliminating use of air pumps, pressure valves, etc. Results of tests demonstrate its economy in comparison with other well-known carburetors.

Developments. The Further Development of Internal-Combustion Engines (Beitrag zur Weiterentwicklung der Verbrennungs-Kraftmaschinen), F. E. Beilefeld. Oel- u. Gasmaschine, vol. 18, no. 7, July 1921, pp. 110–115, 23 figs. Supplementary to article on carburetor problems by Gg. Bergmann in same journal (no. 3, 1921, p. 40).

CARS

Dining. New Dining and Kitchen Carriages for the London-Glasgow Service, Midland and G. & S. W. Railways. Ry. Engr., vol. 42, no. 499, August 1921, pp. 294, 13 figs. Shows improvements in design construction and equipment.

Mine. Loading Machines for Mining Practice (Lastningsmaskiner för underjordisk gruvbrytning), Robert Höök. Jernkontorets Annaler, vol. 105, no. 2, 1921, pp. 97–109, 14 figs. Describes American car loaders, shoveling machines, etc. for underground work.

Motion Recorder. An Automatic Recorder of Vehicular Motion (Indicateur automatique du mouvement des véhicules), E. J. F. Vachet. L'Electricien, vol. 52, no. 1282, August 15, 1921, pp. 367–370, 4 figs. Describes device recording motion of railroad cars and other vehicles, made by Elliot Bros., London.

CASE-HARDENING

Compounds. Carbonizing and Carbonizing Materials, H. B. Knowlton. Trans. Am. Soc. For Steel Treating, vol. 1, no. 11, August 1921, pp. 689–698. Discusses case-hardening and case-hardening compounds.

CEMENT

Bulk. An Investigation into the Use of Bulk Cement. Eng. News-Rec., vol. 87, no. 8, Aug. 25, 1921, pp. 324–326. Discussion of its use on large concrete building jobs, prepared by staff of Turner Constr. Co., New York City.

CEMENT MANUFACTURE

Rotary-Grate Shaft Kilns. The Automatic Rotary-Grate Shaft Kiln, C. F. Hansen. Rock Products, vol. 24, no. 18, Aug. 27, 1921, pp. 33–40, 14 figs. How European portland-cement manufacturers are meeting rapidly increasing fuel and labor costs. Summarizes savings in cement plant with yearly output of 300,000 bbl. in using rotary-grate shaft kilns instead of rotary kiln.

CEMENT MILLS

Hungary. A Cement Mill in Torda, Hungary (Die Zementfabrik in Torda), Hugó Szèkely and Ernst Havas. Beton u. Eisen, vol. 20, nos. 4–5, 6 and 7–8, Mar. 7, Apr. 4 and May 4, 1921, pp. 41–43, 66–69 and 87–90, 35 figs. Description of cement mill operated with natural gas, and manufacturing process. Details of reinforced-concrete structures of plant.

CHUCKS

Magnetic. Electromagnetic Fastening of Large Workpieces on Planing and Surface-Grinding Machines (Elektromagnetische Aufspannung Grösserer Werkstücke auf Hobel- und Flächenschleifmaschinen), A. W. Schultz. Werkstattstechnik, vol. 15, no. 15, Aug. 1, 1921, p. 451, 2 figs. Describes magnetic holding plates of wrought iron having a tensile force of 10 to 12 kg. per sq. cm. as compared to 4 to 5 kg. with use of cast iron or steel casting.

Magnetic Chucks—IX, Ellsworth Sheldon. Am. Mach., vol. 55, no. 10, Sept. 8, 1921, pp. 383–386, 7 figs. Supporting pieces of irregular shape on a magnetic chuck. Testing a chuck to determine its class.

COAL

Carbonization. The Carbonization of Coal at Low Temperature, John Roberts. Iron & Coal Trades Rev., vol. 103, no. 2789, August 12, 1921, pp. 193–196, and Discussion pp. 196. Discusses expansion of coal and its prevention, dealing with swelled coal; essentials of good semi-coke, etc. Paper read before North of Eng. Inst. Min. & Mech. Engrs.

Combustion and Gasification. The Combustion and Gasification of Coal on the Grate (Die Verbrennung und Vergasung von Kohle auf dem Rost), H. Schmolke. Zeit. für Dampfkessel u. Maschinenbetrieb, vol. 44, no. 19, May 13, 1921, pp. 145–147. Notes on development in study of phenomena in connection with combustion or gasification of coal.

Eastern U. S. How Rank of Eastern Coal Changes with Location, R. Dawson Hall. Coal Age, vol. 20, no. 7, August 18, 1921, pp. 257–259, 4 figs. Volatile matter and moisture decrease as East is approached, decline of volatile matter starts not far from Pennsylvania-Ohio line.

Preparation. Advances in Preparation of Anthracite, Dever C. Ashmead. Min. & Metallurgy, no. 177, Sept. 1921, pp. 47–48. History of development. Investigation of five methods of cleaning anthracite. (Abstract.) Paper before Am. Inst. Min. & Metallurgical Engrs.

COAL WASHING

Processes. Modern Coal Washing (La Technique Moderne du Lavage des Charbons), C. Berthelot. Chaleur & Industrie, vol. 2, no. 15, July 1921, pp. 393–401, 8 figs. Discusses importance of coal washing from economical standpoint and describes processes and apparatus for the purpose. (To be continued.)

Notes on Coal Washing By Means of "Rhéolaveurs" (Quelques Notes sur le Procédé de Lavage Par "Rhéolaveurs"), A. France-Focquet. Révue Universelle des Mines, vol. 9, no. 1, S. 6, April 1, 1921, pp. 1–13, 8 figs. Discusses operation of washing fines. (To be continued.)

COKE

Blast-Furnace. Characteristics of Blast Furnace Coke (Sur les Caracteristiques du Coke de Haut-Fourneau), Pierre Kersten. Révue Universelle des Mines, vol. 10, no. 1, Series 6, July 1, 1921, pp. 27–34. Describes physical and chemical properties. (To be continued.)

COKE OVENS

By-Product. New Coke-Oven and By-Product Plant at the Acklam Works of the North-Eastern Steel Company, Limited. Iron & Coal Trades Rev., vol. 103, no. 2788, August 5, 1921, pp. 161–164, 6 figs. Description of new plant, consisting of 60 vertical-flued ovens and recovery equipment.

COLUMNS

Eccentric Loading. Eccentric Loading of Bars and Columns, Edward Ingham. Practical Engr., vol. 64, no. 1795, July 21, 1921, pp. 39–40. Discusses formulas for calculating stresses on eccentrically loaded columns.

Pipe. Strength of Pipes as Columns, John S. Watts. Am. Mach., vol. 55, no. 9, Sept. 1, 1921, p. 341, 1 fig. Presents chart for calculating size of pipe necessary to support a given load as a column of given length.

COMBUSTION

Control. Controlling Combustion on Basis of CO_2 Alone Unsatisfactory. Am. Mar. Engr., vol. 16, no. 11, June 1921, pp. 35–41, 4 figs. Discusses essentials in attainment of maximum economy in combustion control. (To be continued.)

Preheated Air for. The Importance of Heated Combustion Air for Conservation of Coal in Germany (Die Bedeutung der erhitzten Verbrennungsluft für Deutschlands Kohlenwirtschaft), Eugen Haber. Zeit. für Dampfkessel u. Maschinenbetrieb, vol. 44, no. 23, June 10, 1921, pp. 179–181, 3 figs. Discussion of advantages of use of heated air for furnaces.

COMPASSES

Aerial Navigation. Compass for Aerial Navigation (Le Compas de Navigation Aerienne), L. Condroyer. L'Aeronautique, vol. 1, no. 9, February 1920, pp. 387–395, 20 figs. Describes Kelvin, Greach-Osborne and A.M.-1 Compasses.

Gyrostatic. The Anschütz and Sperry Gyrostatic Compasses (Sur les compas gyrostatiques Anschütz et Sperry), H. Beghin. Comptes rendus de l' Académie des Sciences, vol. 173, no. 5, August 1, 1921, pp. 288–290. Discusses equations governing their small oscillations.

CONCRETE

Centrifugally Cast. Centrifugal Machine Casts Solid Concrete Shapes, Leon Cammen. Eng. News-Rec., vol. 87, no. 9, Sept. 1, 1921, p. 366, 1 fig. Describes machine for centrifugal casting of solid concrete shapes, patented by Cammen Laboratories, New York.

Disintegration in Alkali Soils. The Disintegration of Concrete in Alkali Soils, G. M. Williams. Jl. Eng. Inst. Can., vol. 4, no. 8, Aug. 1921, pp. 446–455, 8 figs. Summary of results of laboratory studies together with details of Bur. of Standards field investigations.

Specifications. Tentative Specifications for Concrete and Reinforced Concrete. Proc. Am. Soc. Civ. Engrs., vol. 47, no. 6, Aug. 1921, pp. 60–124, 18 figs. Report of joint committee on standard specifications for concrete and reinforced concrete. Notes on proportioning and mixing, and depositing concrete; forms; details of construction; water-proofing and protective treatment; surface finish; and design.

Strength. Effect of Age on Strength of Concrete, Duff A. Abrams. Mun. & County Eng., vol. 61, no. 2, August 1921, pp. 47–49, 2 figs. Defends view that concrete does not decrease in strength with age.

CONCRETE, REINFORCED

Sea Water, Use in. The Use of Reinforced-Concrete in or Near Sea Water, Arthur S. Tuttle. Mun. Engrs. Jl., vol. 7, 2nd quarterly issue, 1921, pp. 66–84. Suggests rules to ensure reliable results with reinforced concrete in sea water. Reprint of report to Board of Estimate and Apportionment of N. Y. C.

CONDENSERS, STEAM

Leakage Detection. Simplified Chemical Method of Detecting Surface Condenser Leakage, W. E. Caldwell. Power, vol. 54, no. 4, July 26, 1921, pp. 141–142, 1 fig. Tells how to make up solutions for estimating amount of leakage of raw water into condenser.

The Electrical Method of Detecting Surface Condenser Leakage, W. E. Caldwell. Power, vol. 54, no. 6, Aug. 9, 1921, pp. 217–219, 7 figs. Method of obtaining continuous graphic record of leakage by measuring and recording electrical conductivity of condensate.

Surface. Marine Surface Condensers and Condenser Auxiliaries. Am. Mar. Engr., vol. 16, nos. 10 and 11, May and June 1921, pp. 28–33, 6 figs., and 23–27, 17 figs. May: Contains diagrams showing theoretical ratio of injection water of steam for different vacua and water temperatures, also maximum permissible air leakage for different sizes of marine turbine and reciprocating engine condensing plants. June: Discusses live-steam, back-pressure and condensate pumps.

Recent Improvements in Condensers for Steam Engines (Recents perfectionnements des appareils de condensation des machines a vapeur d'eau) L. Jauch. Chaleur et Industrie, vol. 2, no. 15, July 1921, pp. 416–418, 1 fig. Discusses surface condensers, including Brown-Boveri type. (To be continued.)

CONNECTING RODS

Aluminum. Aluminum Connecting Rods (Bielles en Aluminium), A. Dat. Arts et Metiers, vol. 74, no. 8, May 1921, pp. 141–144, 9 figs. Details of construction, alloys suitable, etc.

Machining Automobile. Milling Automobile Connecting-rods, J. M. Henry. Machy. (N. Y.), vol. 27, no. 12, Aug. 1921, pp. 1104–1105, 4 figs. Equipment and methods used in machining Chevrolet, Hinkley and Duesenberg connecting rods.

CONVEYORS

Belt. Belt Conveyor System in Chicago's New Parcel-Post Station. Belting vol. 19, no. 2, August 1921, pp. 17–20, 4 figs. Eighteen conveyors, compactly arranged in tiers, afford quick and efficient separation and distribution to pouches.

Metal Belts. Metal Conveyor Belts with Wide Joint Support (Metallförderbänder mit breiter Gelenkauflage). Fördertechnik u. Frachtverkehr, vol. 14, no. 1, Jan. 7, 1921, pp. 11–12, 6 figs. Describes belt patented by Louis Herrmann, Dresden, with which 95 to 97 per cent of width of link pin is utilized as supporting surface.

COPPER

Sheet. Sheet Copper and Its Sphere of Usefulness, B. Goldsmith. Raw Material, vol. 4, no. 8, August 1921, pp. 268–272, 7 figs. Discusses technical production, prices, and the many uses of sheet copper.

COST ACCOUNTING

Defects in. What is Wrong With Cost Accounting? G. Charter Harrison. Management Eng., vol. 1, no. 1, July 1921, pp. 29–32. Defects of present methods.

Manufacturing Cost. The Elements in Manufacturing Cost, Frederic H. Leland. Management Eng., vol. 1, no. 2, Aug. 1921, pp. 87–88. Discusses three groups of manufacturing costs, namely, general plant expenses, foundry cost and expenses, and manufacturing departments costs and expenses.

COST SYSTEMS

Modern. Disclosing Waste Through Better Cost Methods, Ernest J. Wessen. Chem. & Metallurgical Eng., vol. 25, no. 9, Aug. 31, 1921, pp. 389–393. Claims that many industrial failures are traceable to blind dependence on cost determined by rule-of-thumb methods. Modern cost systems disclose waste in unprofitable products, idle labor and machinery and erroneous methods.

CRANES

Floating. A 60-Ton Self-Propelling Floating Crane. Engineer, vol. 132, no. 3420, July 15, 1921, pp. 72–73, 2 figs. Also in Shipbldg. & Shipg. Rec., vol. 18, no. 6, Aug. 11, 1921, p. 181. Slewing and derricking type of crane built by Werf Gusto (Firma A. F. Smulders), Schiedam, Holland, for Manchester Ship Canal Co.

CRANKCASES

Machining Operations. Machining the Peerless Upper Crankcase, Fred H. Colvin. Am. Mach., vol. 55, no. 10, Sept. 8, 1921, pp. 376–380, 20 figs. Method of handling upper or main crankcase in

CRANKPINS

Machine for Turning. A New Crankpin Turning Machine. Eng. Production, vol. 3, no. 46, Aug. 18, 1921, pp. 155-156, 3 figs. Mechanism of machine designed for economical production, constructed by George Richards & Co., Ltd., Manchester, England.

CUPOLAS

Smelting Process, Regulation of. Cupola Practice (Beiträge zur Kenntnis des Kuppelofenbetriebes), Fritz Braun and Georg Hollender. Stahl u. Eisen, vol. 41, no. 30, July 28, 1921, pp. 1021-1027, 9 figs. Shows how, with aid of diagrams obtained from self-recording blast-capacity measurements, it is possible, with use of blast-furnace-gas investigations, to regulate smelting process of cupola. A graphic method is described for determining maximum CO_2 content of blast-furnace gases.

CYLINDERS

Boring. Cylinder Boring. Eng. Production, vol. 3, no. 45, August 11, 1921, pp. 127-132, 17 figs. Discusses principles and practice.

Calculation of Wall Strength. Graphic Determination of the Strength of Walls in Hollow Bodies (Graphische Bestimmung von Wandstäaken bei Hohlkörpern), Arthur Balog. Zeit. für Dampfkessel u. Maschinenbetrieb, vol. 44, no. 4, Jan. 28, 1921, pp. 28-29. Describes method applicable to hollow cylinders with internal pressure.

Thick. The Thickness of Hydraulic Cylinders, H. S. Cattermole. Mech. Wld., vol. 52, no. 1805, August 5, 1921, pp. 102-103, 1 fig. Discusses well-known fact that thick cylinders are not as strong relatively as thin ones.

D

DIES

Die-Sinking Machines. Keller Automatic Die Sinking Machine. Am. Mach., vol. 55, no. 10, Sept. 8, 1921, pp. 389-390, 6 figs. All movements electrically controlled; inexpensive masters of wood or plaster used; tracer bears lightly on master, while cutter works under pressure.

DIESEL ENGINES

Appraising. Appraising the Diesel Engine Plant, Allen F. Brewer. Indus. Management, vol. 62, no. 3, Sept. 1, 1921, pp. 172-176, 4 figs. Important features that must be considered and analyzed. Calculation and estimation of cost data and depreciation.

Damaged Shafts. Damages to Shafts in Diesel Engines (Wellenbeschädigungen an Dieselmaschinen), Arthur Balog. Zeit. fur Dampfkessel u. Maschinenbetrieb, vol. 44, no. 20, May 20, 1921, pp. 153-154, 9 figs. Discusses examples of breaks in shafts of Diesel engines and their causes.

German Submarine. U-Boat Oil Engines and Recent Developments of the Diesel Engine (U-Boot-Oelmaschinen und neuere Entwicklungsformen der Dieselmaschine), H. Rohwer. Zeit. für Dampfkessel u. Maschinenbetrieb, vol. 44, nos. 9 and 10, Mar. 4 and 11, 1921, pp. 65-67 and 74-77, 14 figs. Discussion of different types and improvements by Körting Bros., Benz, Nürnberg-Augsburg Machine Works, Germania Shipyards, etc.

Marine. Marine Diesel Engine Operation (La Condite des Moteurs Diesel Marins), Le Gallou. Bulletin Technique du Bureau Veritas, vol. 3, no. 6, June 1921, pp. 138-142, 4 figs. Continuation of discussion on causes of bad performances. (To be continued.)

Modern Marine Oil Engines—II-VI. Engineer, vol. 132, nos. 3418, 3420, 3422, 3423, and 3424, July 1, 15 and 29, Aug. 5 and 12, 1921, pp. 2-3, 4 figs., 55-57, 11 figs., 109-111, 6 figs., 136-137, 3 figs. and 174-176, 6 figs. July 1: New type 3200-i.hp. Harland & Wolff Diesel marine engine. July 15: Vickers 1250-b.hp. type. July 29: North British 2330-i.hp. type. Aug. 5: 1400-i.hp. Werkspoor type. Aug. 12: 1250-b.hp. Sulzer 2-cycle engine.

Notes on the Management of Marine Diesels, Homer McCrirrick. Marine Eng. of Can., vol. 11, no. 7, July 1921, pp. 10-14, 6 figs. Compares four-cycle and two-cycle diesels and discusses various features in detail.

Problems in the Manufacture of Marine Diesel Engines. Machinery (Lond.), vol. 18, no. 461, July 28, 1921, pp. 513-514, 4 figs. Choice of material and methods of machining Diesel-engine parts.

DRILLING MACHINES

Portable. Portable Drilling Practice—IX. Mech. Wld., vol. 52, no. 1807, August 19, 1921, pp. 138-139, 2 figs. Discusses vertical- and horizontal-spindle machine made by W. Asquith, Ltd., Halifax. (Concluded.)

DROP FORGING

Dies. Design and Making of Drop-forging Dies. Machy. (N. Y.), vol. 27, no. 12, Aug. 1921, pp. 1141-1144, and vol. 28, no. 1, Sept. 1921, pp. 33-36, 12 figs. Methods employed in modern drop-forging plants.

DRYING PLANTS

Precalculation. The Precalculation of Drying Plants with Special Regard to Duration of Drying Process (Die Vorausberechnung von Trockenanlagen, unter besonderer Berücksichtigung der Trockendauer, M. Hirsch. Gesundheits-Ingenieur, vol. 44, no. 29, July 16, 1921, pp. 357-360, 7 figs. Formulas and curves are derived based on investigations and their application is shown in numerical examples.

d'Aluminium), J. Dyrion. La Houille Blanche, vol. 20, no. 53-54, May-June 1921, pp. 109-113, 5 figs. Discusses properties, composition and manufacture of duralumin. (To be continued.)

E

ECONOMIZERS

Kablitz. The Kablitz Small-Water-Space Economizer (Der Kleinwasseraum-Ekonomiser Bauart Kablitz), Harry Fahrbach. Zeit. für Dampfkessel u. Maschinenbetrieb, vol. 44, no. 12, Mar. 25, 1921, pp. 89-92, 11 figs. Notes on design and uses of the Kablitz economizer, and results of tests carried out by Kirsch in 1910-12 in the boiler laboratory of Mechanical Institute of Moscow Technical Academy.

EDUCATION, ENGINEERING

Improvements in Training. The College Trained Engineer, C. Edward Magnusson. Jl. Am. Inst. Elec. Engrs., vol 40, no. 9, Sept. 1921, pp. 730-736. Suggestions for improvement.

ELECTRIC DRIVE

Food Industry. Electrical Service Aids a Leading Western Food Industry. Jl. Elec. & Western Ind., vol. 47, no. 4, August 15, 1921, pp. 146-147, 5 figs. Shows that introduction of electric driving has improved operating conditions and lowered production costs.

Machine Tools. Electric Motor Drive for Machine Tools, Gordon Fox. Ry. Elec. Engr., vol. 12, no. 8, August 1921, pp. 317-321, 5 figs. Discusses relative advantages of different types of motors.

ELECTRIC FURNACES

Ajax-Wyatt. The Ajax-Wyatt Electric Furnace, John B. C. Kershaw. Engineer, vol. 132, no. 3423, Aug. 5, 1921, pp. 139-140, 4 figs. Details of improved type. For special work of melting yellow brass, on scale which permits continuous operation of furnace, it is said to be most efficient type.

Design. Electric Furnace Operating Experiences, Larry J. Barton. Iron Age, vol. 108, no. 10, Sept. 8, 1921, pp. 581-584, 6 figs. Experiments with three forms of furnace bottom. Methods of building bottoms. Experiments with roof and sidewalls. Metallurgical features.

Non-Ferrous. Melting Steel in a Non-Ferrous Electric Furnace. Iron Age, vol. 108, no. 8, Aug. 25, 1921, p. 472, 1 fig. Successful production of crucible quality steel in small Baily resistance unit.

Tagliaferri. New Italian Electric Furnace (Nuovo forno electrico italiano), Mario Marantonio. Il Forno Electrico, vol. 3, no. 4, April 15, 1921, pp. 41-50, 14 figs. Describes Tagliaferri furnace recently installed at Grandi Acciaiere e Fonderie Gio. Ansaldo.

ELECTRIC LOCOMOTIVES

Development. Possibilities in the Development of Electric Locomotives (Entwicklungsmöglichkeiten der elektrischen Vollbahnlokomotive), Egon E. Seefehlner. Schwerzerische Bauzeitung, vol. 78, nos. 2 and 3, July 9 and 16, 1921, pp. 15-18 and 30-33, 16 figs. Points out advantages and disadvantages of the three types in common use, namely, direct-drive, geared, and underslung motor geared. Discusses possibility of developing a type combining advantages of all three types with elimination of their defects.

Oerlikon. New Single-Phase Locomotives of the Swiss Railways (Les Nouvelles Locomotives Monophasées des Chemins de Fer Féderaus), Lucien Pahin. L'Industrie Electrique, vol. 30, no. 699, August 10, 1921, pp. 285-290, 7 figs. Describes the 2-6+6-2 Oerlikon type of Gothard line, its mechanical and electrical equipment.

Parallel-Crank Drive. Vibratory Phenomena of the Parallel-Crank Drive of Electric Locomotives (Ueber Schüttelerscheinungen des Parallelkurbelgetriebes elektrischer Lokomotiven), Iwan Döry. Schweizerische Bauzeitung, vol. 78, no. 6, Aug. 6, 1921, pp. 63-66, 4 figs. Supplementary remarks to author's article published in Elektrotechnische Zeit. (vol. 41, Apr. 22, 1920, p. 313) in reply to criticisms of work by A. Wichert.

Standardization. The Serialization of Electric Locomotives as a Basis for Their Standardization (Ueber Reihenbildung elektrischer Lokomotiven als Voraussetzung für ihre Vereinheitlichung), A. Wichert. Annalen für Gewerbe u. Bauwesen, vol. 88, nos. 11 and 12, June 1 and 15, 1921, pp. 93-98 and 105-113, 8 figs. It is shown that with proper reduction of frictional weight of a.c. trunk-line locomotives according to a geometrical series with increase of $\sqrt{2}$ and the same reduction of maximum speeds, outputs of from 45 to 127 km. per hr. max. speed and with 2 to six driving axles can be obtained from only 3 motor and 2 transformer basic types for all 14 types of locomotives used in Germany.

Steam vs. Mechanical Advantages of Electric Locomotives Compared With Steam Engines, V. L. R. Raven. Elec. Rev. (Lond.), vol. 89, no. 2280, August 5, 1921, pp. 194 and (discussion) pp. 194-195. (Abstract.) Paper read before Eng. Conference, 1921.

Transmissions. A New Power Transmission System Between Motors and Axles of Electric Locomotives (Norveau Systeme de Transmission de Mouvement entre les Moteurs et les Essieux des Locomotives Electriques), M. Auvert. Révue Générale des Chemins de Fer et des Tramways, vol. 40, no. 8, August 1921, pp. 88-96, 6 figs. Describes system based on connecting rods in which vibrations of locomotive have no deleterious effect.

and Motors, H. D. Wheeler. Electrician, vol. 87, no. 2254, July 29, 1921, pp. 136-138, 9 figs. Indicates briefly some of the main causes of vibration in turbo-generators and similar machines and how to overcome it.

ELECTRIC MOTORS

Overload Protection. Overload Protection of Motors Edgar P. Slack. Power, vol. 54, no. 4, July 26, 1921, pp. 132-133. Use of fuses, circuit breakers and motor starters.

ELECTRIC RAILWAYS

Starting System. New Starting System for Traction by Continuous Current; Inductive Starters (Nouveau Système de Démarrage pour la Traction par Courant Continu: Les Démarreus Inductifs), Armand Givelet. Révue Générale de L'Electricité, vol. 10, no. 4, July 23, 1921, pp. 133-137, 6 figs. Describes new, simple method for which considerable saving in current is claimed.

Three-Wire Distribution. Three-Wire Railway Distribution in Wilmington, A. P. Way. Elec. Ry. Jl., vol. 58, no. 9, August 27, 1921, pp. 307-311, 5 figs. Improves regulation and prevents electrolysis. Trial proves system best adapted to radial city districts.

Trolley Systems. Electric Overhead Line Systems (Note sur les lignes caténaires pour prise de courant aérienne destinées à l'électrification des voies d'intérêt général). Paul Leboucher. Révue Générale de l'Électricite, vol. 10, no. 6, August 6, 1921, pp. 195-201, 16 figs. Discusses pantograph trolley and feeding of current. (To be continued.)

ELECTRIC WELDING

Methods. Electric Welding Apparatus (Les Machines a Souder), Ch. Andry-Bourgeois. L'Electricien, vol. 52, no. 1282, August 15, 1921, pp. 361-367, 8 figs. Discusses various methods of electric welding and uses made of them. (To be continued.)

ELECTRIC WELDING, ARC

Electric-Railway Work. Electric Arc Welding, Henry M. Sayers. Elec. Ry. & Tramway Jl., vol. 45, no. 1091, August 12, 1921, pp. 129-132 and (discussion) pp. 132-133, 7 figs. Deals with failures, welding of lattice masts, covered and bare electrodes, etc. Paper read before Tramways & Light Rys. Assn.

Fillet and Butt Welding. Fillet and Butt Welding by the Electric Arc. Can. Machy., vol. 26, no. 6, August 11, 1921, pp. 33-34 and 53, 2 figs. Discusses welds by spreading, butt welding, double "V" weld.

Machines. A New Electric Arc Welding Machine. Engineer, vol. 132, no. 3418, July 1, 1921, pp. 18-19, 5 figs. Details and working of new machine known as cyc arc, because of regular cycle of operations on which its success depends and which it accurately performs.

ELECTRIC WELDING, RESISTANCE

Spot-Welding Machines. Spot-Welding Machines (Machine a Souder par Points), P. Saurel. Arts et Métiers, vol. 74, no. 9, June 1921, pp. 173-177, 13 figs. Describes principle, apparatus and operation.

Spot Welding Machine for Making Ships' Ventilators. Engineer, vol. 132, no. 3424, Aug. 12, 1921, p. 176, 1 fig. New type of electric machine for manufacture of large ventilating cowls for steamships, and other bulky hollow sheet-metal articles of similar nature.

ELEVATORS

Safety Devices. Electric Elevator Machinery—Car Safeties, M. A. Myers. Power, vol. 54, no. 5, Aug. 2, 1921, pp. 176-177, 6 figs. Describes heavy-duty double-eccentric, compression-type and flexible guide-clamp type safety.

EMBOSSING

Dies. Making Embossing Dies for Emblematic Work, Chas. E. Hall. Can. Mach., vol. 26, no. 7, August 18, 1921, pp. 36-38, 5 figs. Discusses hub method, "cut in" system, and their combination.

EMPLOYEES, TRAINING OF

Economic Advantages. Training as a Factor in Reducing Labor Cost, J. F. Johnson. Management Eng., vol. 1, no. 1, July 1921, pp. 5-9, 5 figs. How instructing the worker enhances his skill, increases production and lowers manufacturing costs.

Training as a Factor in Reducing Waste, J. F. Johnson. Management Eng., vol. 1, no. 2, Aug. 1921, pp. 93-97, 6 figs. How teaching of correct working habits will develop skill, reduce labor turnover and save material.

EMPLOYMENT MANAGEMENT

Personnel, Selection and Placement of. The Personnel Problem: To Eliminate the Waste of Human Effort, L. B. Hopkins. Chem. & Metallurgical Eng., vol. 25, no. 9, Aug. 31, 1921, pp. 385-388. States that many wastes of time and production can be attributed to improper selection and placement of personnel and to management's failure to recognize value of training, transfer and promotion of deserving employees.

Present Need of. Is Personnel Management Essential Now? Earl B. Morgan. Management Eng., vol. 1, no. 2, Aug. 1921, pp. 89-92. Points out that pressing labor problems must be solved in periods of force reductions as well as in times of shortage of workers.

ENGINEERING LITERATURE

Classification and Indexing. Classifying and Indexing the Clipping File, Harrison W. Craver, Management Eng., vol. 1 no. 1, July 1921, pp. 49-50.

Applying use of decimal classification system to engineering literature. Adoption by Engineering Societies library. Plan of Management Engineering.

ENGINEERS

Problems Confronting. The Pioneer Spirit in Engineering, E. S. Carman. Management Eng., vol. 1, no. 1, July 1921, pp. 1–3. As developed in Federated Am. Eng. Societies. Notes on engineers' problem of future; two major influences in engineering elimination of waste in industry.

EXPANSION

Thermal. The Thermal Expansion of Certain Materials (Ueber die Wärmeausdehnung einiger Stoffe), Karl Scheel. Deutsche Optische Wochenschrift, vol. 7, no. 31, July 31, 1921, pp. 562–563. Results of experiments carried out in German National Physical-Technical Inst. with different materials according to the Fizeau and the so-called tube method.

F

FACTORIES

Design. The Design and Construction of Engineering Workshops—XXI, Ernest G. Beck. Mech. Wld., vol. 52, no. 1806, August 12, 1921, pp. 122–123, 5 figs. Continues discussion of construction of roofs. (To be continued.)

Location. Location as a Factor in Eliminating Industrial Waste, Victor V. Kelsey. Chem. & Metallurgical Eng., vol. 25, no. 9, Aug. 31, 1921, pp. 401–402. Main factors to be considered are: Influence which proposed industry will have on community, raw materials, transportation, labor supply and power.

The Scientific Location of Manufacturing Plants, J. George Frederick. Indus. Management, vol. 62, no. 3, Sept. 1, 1921, pp. 153–155, 1 fig. Deals with considerations that govern proper location of manufacturing plant and conditions arising due to shift of population or manufacturing centers.

Layout. Developing an Industrial Plant Layout, A. T. Doud. Indus. Management, vol. 62, no. 3, Sept. 1, 1921, pp. 149–152, 4 figs. Points out that in complete design of new plant, it is necessary to work out together the general production system, department layout and general features of building construction in order to insure well-balanced plant.

FACTORY MANAGEMENT

See INDUSTRIAL MANAGEMENT.

FATIGUE

Testing. Improvements in Methods of Fatigue Testing, H. J. Gough. Engineer, vol. 132, no. 3424, Aug. 12, 1921, pp. 159–162, 13 figs. Report submitted to materials and chemistry committee of Aeronautical Research Committee. Experiments on alternating torsion; forms of test pieces; strain measurements; method of test using strain and calorimetric methods simultaneously, etc.

FIRE HAZARDS

Review of. Some Considerations on Fire Waste, Nicholas Richardson. Chem. & Metallurgical Eng., vol. 25, no. 9, Aug. 31, 1921, pp. 397–400. Industry in general, and chemical industry in particular, is said to be in need of fuller appreciation of fire hazards and appalling waste due to destruction by fire. Review of possible fire hazards.

FIRE PROTECTION

Slow-Burning Buildings. Specifications for "Slow Burning" Office Buildings, Ira H. Woolson. Eng. & Contracting, vol. 56, no. 8, Aug. 24, 1921, pp. 178–179. Report submitted by committee on building construction of Nat. Fire Protection Assn. containing proposed specifications for rendering so-called non-fireproof class of commercial buildings reasonably slow-burning.

FIREPROOFING

Cotton Fabric. The Effect of Certain Fire-Proofing Solutions on Cotton Fabric, R. L. Sibley. Jl. Ind. & Eng. Chem., vol. 13, no. 8, August 1921, pp. 676–677, shows that sodium, tungstate has the least weakening action and recommends it as an excellent fireproofing agent.

FLIGHT

Soaring. Mechanical Models for Soaring Flight (Mechanische Modelle zum Segelflug), Th. v. Karman. Zeit. für Flugtechnik u. Motorluftschiffahrt, vol. 12, no. 14, July 30, 1921, pp. 220–223, 4 figs. Simple mechanical devices for study of energy and speed conditions in connection with soaring flight.

Soaring (Bemerkungen über den Segelflug), L. Prandtl. Zeit. fur Flugtechnik u. Motorluftschiffahrt, vol. 12, no. 14, July 30, 1921, pp. 209–211. Discusses possibilities of soaring; sources and utilization of energy in soaring flight of birds and men. Conditions for minimum descending speed are investigated and numerical example given.

FLOW OF WATER

Chézy Formula. Antoine Chezy. History of an Hydraulic Formula (Antoine Chezy. Histoire d'une Formule d'Hydraulique), G. Mouret. Annales des Ponts et Chaussees, vol. 59, no. 2, 11th Series, March-April 1921, pp. 165–268. His formula $U = C\sqrt{(RI)}$ for flow of water. Bibliography.

Gibson Method. Theoretical Discussion of the Hydrometric Method of N. R. Gibson (Theoretische Erörterungen zur Wassermessmethode von N. R. Gibson). Schweizerische Bauzeitung, vol. 78, no. 4, July 23, 1921, pp. 41–43. Refers to method described in Canadian Engineer (vol. 39, no. 12, Sept. 16, 1920), and points out that it is difficult to fulfill all the conditions required in application of method, which, in author's opinion, represents no progress in hydrometry.

Photographic Measurement. Use of Photography in Hydraulic Measurements in India, S. C. Majumdar Eng. News-Rec., vol. 87, no. 10, Sept. 8, 1921, pp. 414–415, 2 figs. Photographic tests made on large jets are said to check remarkably close with actual gagings by current meter.

Venturi Tubes. Nomograms for Calculating Flow in Venturi Tubes, J. W. Ledoux. Eng. & Contracting, vol. 56, no. 6, Aug. 10, 1921, pp. 138–139, 3 figs. Three nomograms are presented and their uses explained.

FLYING BOATS

Construction. Flying Boat Construction, David Nicolson. Aeronautical Jl., vol. 25, no. 128, August 1921, pp. 385–412 and (discussion) pp. 413–420, 16 figs. Gives details of construction of types F, P and N; concludes that in an aero-engine a high degree of compression is essential and that tests established the possibility of supercompression as a means of power recuperation at high altitude.

Leoning Model. The Leoning Model 23 Flying Yacht. Aviation, 11, no. 9, August 29, 1921, pp. 248–250, 5 figs. Gives data of machine and describes test recently made.

FOUNDRIES

Brass and Aluminum. Features of a Non-ferrous Metal Foundry, F. L. Prentiss. Iron Age, vol. 108, no. 9, Sept. 1, 1921, pp. 511–513, 3 figs. Outstanding features of new jobbing brass and aluminum foundry of National Bronz & Aluminum Foundry Co., Cleveland, Ohio.

Casting Costs. Promoting Economy in Iron Foundries by Means of Uniform Rules and Fundamental Principles for the Production and Evaluation of Castings (Die Erhöhung der Wirtschaftlichkeit un der Eisengiesserei durch einheitliche Leitsätze und Unterlagen für die Herstellung und Bewertung der Gusserzeugnisse), Joh. Mehrtens. Betrieb, vol. 3, no. 20, July 10, 1921, pp. 613–617, 2 figs. Includes report of work being done by expert committee for foundry products of German Industry Committee on Standards (N.D.I.), and points out importance of adopting standard terms and classifications, specially for cast-iron products.

Continuous. Continuous Foundry for Pipe Fittings, Henry M. Lane. Iron Age, vol. 108, no. 9, Sept. 1, 1921, pp. 519–524, 10 figs. Designed for minimum handling of sand, castings, cores, hot metal and flasks. Layout and details.

Electrical Equipment. Electrical Apparatus in the Foundry, F. D. Egan. Foundry, vol. 49, no. 16, August 15, 1921, pp. 646–651, 16 figs. Discusses cupola and air furnaces, transformers and motor equipment, also gives data on operation of foundries.

Mechanical Control. Mechanical Control in Foundry Problems, J. H. Hopp. Iron Age, vol. 108, no. 8, Aug. 25, 1921, pp. 456–458, 5 figs. Discusses several cases showing how application of simple mechanics produced results which chemistry alone did not. (Abstract.) Address delivered before Southern Metal Trades Assn.

FREIGHT HANDLING

Ashley Planes. Ashley Planes for Handling Freight Traffic, C. H. Stein. Min. & Metallurgy, no. 177, Sept. 1921, pp. 45–46. Notes on installation of hoisting engines of large capacity at head of each plane, which, by means of large cables, haul cars to objective point. (Abstract.) Paper read before Am. Inst. Min. & Metallurgical Engrs.

FRICTION

Rolling. Measuring Accelerations and Coefficients of Rolling Friction At the Metropolitan Railway of Paris (Mesures d'accélérations et de coëfficients de roulement au chemin de fer métropolitain de Paris), R. Van Cauwenberghe. Société Belge des Électriciens, vol. 35, May-June 1921, pp. 101–118, 9 figs. Describes level and electric accelerometers and tests made with former.

FUEL CONSERVATION

Power Plants. Elimination of Waste in Industrial Power Plants, David Moffat Myers. Chem. & Metallurgical Eng., vol. 25, no. 9, Aug. 31, 1921, pp. 413–416. Shall an industry own its power plant or buy its power? Determining factor is relation of heating and process steam to power demand. The what and why of fuel economy.

Reducing Coal Consumption from 51 to 27 Tons a Day, H. A. Ward. Power, vol. 54, no. 5, Aug. 2, 1921, pp. 172–174, 4 figs. Describes changes made in steam-generating plant to effect this reduction.

FUELS

Anthracoal. Anthracoal: A New Domestic and Metallurgical Fuel, Donald Markle. Trans. Am. Inst. Min. & Met. Engrs., No. 1086-C, August 1921, 11 pp., 1 fig. Gives comparative results of tests of anthracoal and coke, analysis of anthracoal, process of manufacture and by-products obtained. (Also in Coal Age, vol. 20, no. 8, August 20, 1921, pp. 296–299.)

Bituminous Coal. Utilization Refinement of Fuels, F. P. Coffin. Gas Age-Rec., vol. 48, no. 5, August 20, 1921, pp. 176–178. Discusses processes for conversion of bituminous coal into primary fuel and power.

Recovery from Furnace Residue. The Schilde Process for the Treatment of Furnace Residue (Das Schildesche Aufbereitungsverfahren für Feuerungsrückstände), A. Pradel. Zeit. fur Dampfkessel u. Maschinenbetrieb, vol. 44, no. 10, Mar. 11, 1921, pp. 73–74, 2 figs. Details of the Kolumbus separator.

Utilization. Commission for Utilization of Fuel (Commission D'Utilisation du Combustible), Revue de L'Industric Minérale, no. 14, July 15, 1921, p. 506. (Continuation of serial.)

[See also LIGNITE; PEAT.]

FURNACES, ANNEALING

Gas-Fired. Gas-Fired Annealing Furnace. Iron & Coal Trades Rev., vol. 103, no. 2786, July 22, 1921, pp. 107, 3 figs. Describes tests made with plant consisting of two self-contained twin-pot rotary flame annealing furnaces.

FURNACES, BOILER

Burning Mixed Fuels. The Burning of Fuel Mixtures (Verfeuerung verschiedenartiger Brennstoffe), Karl Schäfer. Zeit. fur Dampfkessel u. Maschinenbetrieb, vol. 44, no. 17, Apr. 29, 1921, pp. 130–133, 2 figs. Results of combustion tests carried out in 1915 in two-header water-tube boiler of the Berlin municipal gas works, in order to obtain desiderata for an expedient burning of coke and coke mixtures with other fuels. Abstracted from report of Soc. for Promotion of Moor Coal Cultivation.

French Types. Furnace Operation and Coal Conservation in France During the War (Feuerungsbetrieb und Kohlewirtschaft in Frankreich während des Krieges), A. Pradel. Feuerungstechnik, vol. 9, no. 21, Aug. 1, 1921, pp. 193–197, 16 figs. Notes on the Ratel underfeed furnaces; the Godillot furnaces for waste wood; the Serret grates for use of low-grade fuel; the Genevet forced-draft furnaces; the Prat induced-draft system; etc.

Nozzle Grate Bars. Progress in Forced-Draft Furnaces (Neues von Unterwindfeuerungen), A. Pradel. Zeit. für Dampfkessel u. Maschinenbetrieb, vol. 44, no. 22, June 3, 1921, pp. 169–172, 9 figs. Describes nozzle grate bars constructed by Berlin-Anhalt Machine Constr. Corp., Dessau; Dr. Hans Cruse & Co., Berlin-Charlottenburg; and Thost, Zwickau.

FURNACES, INDUSTRIAL

Egler. Adapts Blow Torch Idea To Furnace, George L. Prentiss. Foundry, vol. 49, no. 16, August 15, 1921, pp. 639–640, 1 fig. Describes Egler patent applicable to all kinds of liquid gas and fuel and powdered coal.

Efficiency. The Efficiency of Industrial Furnaces, Hugh Chambers. Can. Machy. vol. 26, no. 7, August 18, 1921, pp. 33–35, 5 figs. Increase in efficiency due to modern design.

Gas and Oil. New Gas and Oil Furnaces (Neue Gas- und Oelfeuerungen), A. Pradel. Zeit. für Dampfkessel u. Maschinenbetrieb, vol. 44, nos. 5 and 6, Feb. 4 and 11, 1921, pp. 33–34 and 43–44, 20 figs. Details of recent German patents.

FURNACES, METALLURGICAL

Heat Losses. The Fundamental Principles of Heat Losses of Metallurgical Furnaces (Die Grundlagen der Wärmeverluste metallurgischer Oefen), P. Rosin. Metall u. Erz, vol. 17, no. 21, Nov. 8, 1920, pp. 463–475 and vol. 18, nos. 2, 4 and 5, Jan. 22, Feb. 22 and Mar. 8, 1921, pp. 37–45, 78–88 and 99–104, 14 figs. Nov. 8: The geometrical factor. Jan. 22: The material factor. Feb. 22: The external heat conductivity; the temperature factor. Mar. 8: The time factor.

G

GAGES

Inspection. The Delco Inspection System, Erik Oberg. Machy. (N. Y.), vol. 27, no. 12, Aug. 1921, pp. 1127–1130, and vol. 28, no. 1, Sept. 1921, pp. 43–47, 23 figs. Typical Examples of gaging fixtures used by Dayton Engineering Laboratories Co. in manufacture and inspection of company's product.

Plug and Ring. The Selection of Gages for Cylindrical Allowances (Auswahl der Lehrenarten für Rundpassungen), K. Gottwein. Werkstattstechnik, vol. 15, no. 13, July 1, 1921, pp. 393–400, 20 figs. Suggestions for an economical selection of gages from the two allowance systems in present use.

GAS PRODUCERS

Development. Developments in the Construction of Gas Producers (Die Entwicklung des Gaserzeugerbaues), H. R. Trenkler. Glasers Annalen für Gewerbe u. Bauwesen, vol. 89, no. 1, July 1, 1921, pp. 3–8, 14 figs. Discusses various types. It is claimed that the revolving-grate producer has replaced all older types.

Operation. Gas-Producer Practice, N. R. Rees. Mech. Wld., vol. 70, no. 1804, July 29, 1921, pp. 89–90. Discusses essential features, even distribution of coal, uniform production of good-quality gas, regulation of depth of fuel bed, removal of ashes and clinker, and low cost of operating.

GEAR CUTTING

Stevenson Multiple Shaper. The Stevenson Multiple Shaper. Machinery (Lond.), vol. 18, no. 463, August 11, 1921, pp. 578–581, 8 figs. A new type of gear-cutting machine.

The Stevenson Gear Wheel Shaping Machine. Engineer, vol. 132, no. 3422, July 29, 1921, p. 128, 2 figs. Details of multiple shaping machine for cutting gear wheels, which cuts all or large proportion of teeth simultaneously.

GEARS

Fabroil. Fabroil and Textoil—Textile Fibre Products that Give Good Service In Gears, G. L. Wilder. Raw Material, vol. 4, no. 8, August 1921, pp. 279–280, 1 fig. Discusses fabroil gears and textoil gears.

vol. 132, no. 3422, July 29, 1921, pp. 112–113, 2 figs. Describes specialist work of grinding of tooth profiles to a stated standard of accuracy performed by Gear Grinding Co., Ltd., Birmingham.

Gear Tooth Grinding. Machinery, (Lond.), vol. 18, no. 462, August 4, 1921, pp. 542–545, 8 figs. Describes system of Gear Grinding Co., Ltd.

Involute. Inspection of Involute Spur and Helical Gear Hobs—I, Carl G. Olson. Machy. (N. Y.), vol. 28, no. 1, Sept. 1921, pp. 11–13, 12 figs. Testing accuracy of hob and tooth parts; hobbing tests.

The Evolution of the Involute Gear Tooth—VII and VIII, A. Fisher. Machinery (Lond.), vol. 18, nos. 461 and 462, July 28 and Aug. 4, 1921, pp. 507–510, 4 figs., and 547–551, 14 figs. Discusses conditions of contact, lengths of contact paths and numbers of teeth.

Maag. Principles of Maag Gearing. Machy. (N. Y.), vol. 28, no. 1, Sept. 1, 1921, pp. 48–52, 9 figs. Analysis of Maag system of gearing, advantages claimed for this type of gears, and machines for their production.

Rolling-Mill Driving. Cutting Rolling Mill Driving Gears, Fred R. Daniels. Machy. (N. Y.), vol. 28, no. 1, Sept. 1921, pp. 1–4, 5 figs. Producing large herringbone gears by end-milling process at Woodard Machine Co.'s plant in Wooster, Ohio.

GIRDERS

Reinforced-Concrete. Construction Joints in Concrete Girders of 62½ Ft. Span. Eng. News-Rec., vol. 87, no. 9, Sept. 1921, pp. 348–350, 4 figs. Unique design is said to safeguard reinforced-concrete garage under Williamsburg bridge against cracking in event of uneven pier settlement.

GLASS MANUFACTURE

Sheet, Drawing. The Drawing of Sheet Glass. Glass Ind., vol. 2, no. 8, August 1921, pp. 190–193, 3 figs. Describes invention of Emile Gobbe developed by Emile Fourcault, and results obtained leaving no doubt as to ultimate success of process. (Abstract, Le Verre.)

GRAIN ELEVATORS

Floating Pneumatic. The Floating Pneumatic Grain Elevator at Avonmouth Dock, George F. Zimmer. Eng. & Indus. Management, vol. 6, no. 8, Aug. 25, 1921, pp. 221–225, 4 figs. Details of pneumatic plant known as the Alpha, which is mounted on pontoon of reinforced concrete divided by concrete bulkheads into separate compartments for accommodation of boiler, engine, elevators, and crew.

GRAIN HANDLING

Pneumatic Plant. Pneumatic Grain-Discharging and Sack-Handling Plant at Bordeaux. Engineering, vol. 112, no. 2904, Aug. 26, 1921, pp. 312–314, 19 figs., partly on p. 316 and supp. plate. Two traveling pneumatic grain-discharging installations, delivering on to elevated belt conveyors running length of wharf; these conveyors deliver in turn to others running at right angles to them, back to silos of 7500 tons capacity, whence grain may be stacked off and stored in warehouses. (To be continued.)

GRINDING

Automobile Parts. Grinding in the Automotive Industry—II, P. M. Heldt. Automotive Ind., vol. 45, no. 7, August 18, 1921, pp. 315–317, 3 figs. Development of specialized forms of grinding. (To be continued.)

Fixtures. Grinding Practice—Variety of Fixtures Used, F. Scriber. Can. Machy., vol. 26, no. 6, August 11, 1921, pp. 28–31, 14 figs. Discusses principles and shows how grinding wheel comes into contact with work.

Some Novel Grinding Fixtures, Andrew Macnab. Am. Mach., vol. 55, no. 8, Aug. 25, 1921, pp. 309–312, 9 figs. Grinding blocks with ends parallel. A fixture that failed and how trouble was remedied.

GRINDING MACHINES

Manufacture. Building Grinding Machines. Eng. Production, vol. 3, no. 45, August 11, 1921, pp. 133–139, 19 figs. Description of products of Churchill Machine Tool Co., Ltd., Manchester, Eng.

H

HANDLING MATERIALS

Automobile Plant. Handling Materials in an Automobile Plant, Fred H. Colvin. Am. Mach., vol. 55, no. 8, Aug. 25, 1921, pp. 292–296, 12 figs. Utilizing elevators and floors openings for carrying material from one floor to next. Continuous assembly and modern devices for facilitating work.

Methods. Moving Parts from Operation to Operation, J. M. Macrae. Management Eng., vol. 1, no. 3, Sept. 1921, pp. 167–169, 4 figs. Discusses four methods: Moving by trucks, rolling down chutes, sliding on gravity conveyors, handling by power conveyors.

HARDNESS

Testing. Hardness Testing (Beitrag zur Härteprüfung), F. Waizenegger. Zeit. des Vereines deutscher Ingenieure, vol. 65, no. 31, July 30, 1921, pp. 824–827, 5 figs. Describes method making use of ball test and exemplifies its practicability.

HEALTH

Chemical Industry. Occupational Diseases in Chemical Industries, Frederic Dannerth. Indus. Management, vol. 62, no. 3, Sept. 1, 1921, pp. 145–147, 4 figs. How workers in chemical plants are safeguarded.

E. Mock. Chem. & Metallurgical Eng., vol. 25, no. 9, Aug. 31, 1921, pp. 369–374, 2 figs. Strong emphasis is placed on role of physician in industrial plants, with outline of preventive and curative medical services which can be rendered to working forces in industry.

HEAT

Conservation. Premiums for the Saving of Heat (Ersparnisprämien in der Wärmewirtschaft), Friedrich Münzinger. Zeit. für Dampfkessel u. Maschinenbetrieb, vol. 44, nos. 1 and 2, Jan. 7 and 14, 1921, pp. 1–3 and 9–12, 3 figs. Means and methods of calculating utilization of heat in boiler room, and instruments required for measuring consumption of coal, feedwater and condensation quantities of large turbines, amount of electric energy produced, etc. Curves showing performance of boiler system of the Golpa power station, Germany.

HEAT TRANSMISSION

Liquid to Liquid. Law of Heat Transmission Between Liquids in Heat Exchangers (Lois numériques de la Transmission de la Chaleur entre les fluides dans les Echangeurs industriels) H. Dieterlen. Chaleur et Industrie, vol. 2, no. 15, July 1921, pp. 406–409, 1 fig. Mathematical discussion of speed of transmission, review of previous work on this subject. (To be continued.)

Pipe Lines. Investigations of Heat Transmission in Pipe Lines (Die bisherigen Untersuchungen des Wärmeübergangs in Rohrleitungen mit besonderer Berücksichtigung der Forschungen von Professor Nusselt), H. Schmolke. Zeit. für Dampfkessel u. Maschinenbetrieb, vol. 44, no. 11, Mar. 18, 1921, pp. 81–84. Special consideration of research work of Professor Nusselt.

HEATING

Gas and Electric. Gas and Electric Heating (Chauffage au gaz et chauffage à l'électricité), A. Grebel. Chaleur et Industrie, vol. 2, no. 15, July 1921, pp. 426–432. Comparative analysis concerning domestic heating.

HEATING, ELECTRIC

Granular Metal. Using Granular Metal in Electric Heating (Sur l'emploi des métaux granulaires pour le chauffage électrique), Oct. Douy-Hénault. Académie Royale de Belgique—Mémoires, vol. 6, March 1921, 57 pp., 15 figs. Discusses granular resistances; comparison of carbon resistances with granular metal ones; electric properties of granular metallic masses; granular conductivity; melting point of granular metal etc. in connection with electric furnaces.

HEATING, HOT-WATER

Pipe Resistance. Calculation of the Resistance in Piping for Hot-Water Heating (Die Widerstandsberechnung der Rohrleitungen von Warmwasserheizungen), Otto Ginsber. Gesundheits-Ingenieur, vol. 44, nos. 24 and 28, June 11 and July 9, 1921, pp. 281–293 and 345–350, 9 figs. Tables giving friction values obtained from the Brabbée and other calculating methods. The Brabbée tests are said to prove that small errors in construction of pipe lines can have great influence on result, the magnitude of which however, has not yet been determined; hence the Brabbée investigations do not represent final solution of problem. Writer claims that it is possible, by deviating from theoretical accuracy, to simplify calculations, thereby effecting a great saving in time and in cost of installation, without risk of building inferior or too costly installations.

HEATING, STEAM

Methods. Methods and Basic Principles of Heating with Steam (Arten und rechnerische Grundlagen der Erhitzung mit Dampf), Rudolf Kaesbohrer. Chemiker-Zeitung, vol. 45, no. 9, Jan. 20, 1921, pp. 69–73, 1 fig. Includes table showing relations between pressure, temperature and heat content of saturated steam. Notes on direct and indirect steam heating; heating of air or gas.

HOUSING

Dense Tenement Populations, Eliminating. Population Density as a Basis for Housing Regulations, Frank B. Cartwright. Eng. News-Rec., vol. 87, no. 8, Aug. 25, 1921, pp. 318–322, 3 figs. Intensive Rochester study indicates that improved transit, industrial decentralization, zoning and other current changes render dense tenement populations unnecessary in most cities.

Traffic and. Traffic and Housing in Large Cities, Arthur Ertel. Elec. Ry. Jl., vol. 58, no. 6, August 6, 1921, pp. 199–201, 5 figs. Finds that there exists a definite relation between track and building development within different areas equidistant from a city center. (Abstract from Verkehrstechnik.)

HYDRAULIC PRESSES

Single-Acting. Pressing Stator Plates into Motor Casings, and Rotor Plates on Squirrel Cage Rotors on a Single-Acting Hydraulic Press, J. Blakey and J. Shankley. Eng. & Indus. Management, vol. 6, no. 4, July 28, 1921, pp. 86–87, 13 figs. Equipment designed for use in connection with single-acting hydraulic press.

HYDRAULIC TURBINES

Draft Tubes. Hydro-Electric Practice—Draft Tubes, C. Voetsch. Power, vol. 54, no. 5, Aug. 2, 1921, pp. 164–167, 10 figs. Discussion and comparison of various types of draft tubes.

High-Head Reaction. Important Features in the Design of High-Head Reaction Turbines, F. H. Rogers. Power, vol. 54, no. 7, Aug. 16, 1921, pp. 244–248, 9 figs. A 30,000-hp. unit for Big Creek, no. 8 development of Southern California Edison Co.

Draft tube, casing and relief-valve design. Lubricating of internal parts. Governor control.

Kaplan. The Economic Utilization of Water Energy by Means of the Kaplan Turbine (Die wirschaftliche Ausnutzung der Wasserenergie durch die Kaplan-Turbine), H. Donath. Elektrotechnischer Anzeiger, vol. 38, nos. 95, 96 and 97, June 16, 18 and 21, 1921, pp. 641–644, 649–650 and 659–660, 23 figs. Details and advantages of the Kaplan turbines.

Norway. The Turbines of the Vammua Hydroelectric Works, Norway (Vamma kraftanlægs turbiner), Ch. Woxholt. Teknisk Ukeblad, vol. 68, no. 18, May 6, 1921, pp. 209–212, 8 figs. Deals especially with sixth turbine which differs from older ones. With 214 r.p.m. and 27 m. head, it has output of 14,330 hp.; maximum diameter of casing is 5.7 m. Account of trial run.

Wear. Wear of Hydraulic Turbines (L'Usure des Turbines Hydrauliques)—IV, Henri Dufour. La Houille Blanche, vol. 20, no. 53–54, May-June 1921, pp. 97–104, 13 figs. Description of sand removers used at Ackersand Works.

HYDRAULICS

Eddy Flow. Eddy Flow and Hydrodynamical Conceptions in Connection Therewith (Wirbel und im Zusammenhang damit stehende Begriffe der Hydrodynamik), A. Betz. Zeit. für Flugtechnik u. Motorluftschiffahrt, vol. 12, no. 13, July 15, 1921, pp. 193–198, 19 figs. Based on typical examples, conception of rotation in two-directional motion of liquid is discussed and it is shown that through the pure forces of pressure without friction no rotational motion can be produced. In general, frictional forces are only noticeable in vicinity of solid walls. Discusses law stating that circulation along eddy is constant. Examples of the most frequently occurring forms of eddy.

Recent Progress. New Results in Hydromechanics (Neue Ergebnisse der Hydromechanik), H. v. Sanden. Glückauf, vol. 57, no. 27, July 2, 1921, pp. 629–636, 12 figs. Review of progress in recent years. Notes on Newton's theory on resistance of bodies in agitated liquid; the Euler streamline theory of frictionless liquid; friction of liquids; limit-stream theory of Prandtl; resistance formula, the Reynolds coefficient.

Theory. Contribution to the Theory of Hydraulic Motion (Nuovo Contributo alla Teoria dei Moti Idraulici), P. Alibrandi. Il Nuovo Cimento, vol. 22, Series 6, July-August 1921, pp. 94–113. Navier's hydrodynamic equations are valid for instantaneous velocity and pressure, but not for "hydraulic" velocity and pressure, which author develops mathematically.

HYDROELECTRIC PLANTS

Spain. Hydroelectric Plants of Guadiaro River, Spain (Les usines hydro-électriques du Guadiaro), Adolphe Weber. Schweizerische Bauzeitung, vol. 77, no. 26, June 25, 1921, pp. 299–301, 12 figs. (Concluded.)

Waterwheel Design and Setting. Advances in the Art of Waterwheel Designs and Settings, W. M. White. Jl. Am. Inst. Elec. Engrs., vol. 40, no. 8, Aug. 1921, pp. 668–682, 23 figs. Notes on speed regulation; runners and runner materials; draft tubes; shaft and bearings; guide vanes; governors; turbine casing; vertical vs. horizontal units; control valves; and power house setting.

I

IGNITION

Adjustments. Different Ignition Adjustments and Their Effect on Performance of Engine and Consumption of Fuel (Verschiedene Zündeinstellungen und ihre Wirkung in bezug auf die Motorleistung und den Kraftstoffverbrauch), C. Wirsum. Motorwagen, vol. 24, no. 16, June 10, 1921, pp. 323–327, 21 figs. Discusses various adjustments of spark plugs, and gives chart showing output curves and fuel consumption with different ignitions.

INDUSTRIAL MANAGEMENT

Administrative Planning. Planning Applied to Administration. Eng. & Indus. Management, vol. 6, no. 7, Aug. 18, 1921, pp. 174–177. Indicates to what extent field of industrial administration has been entered by scientific management. Notes on planning of sales, relationship between stock and finished products, and finances.

Budgets and Production. The Expense and Finance Budgets, Park Mathewson. Indus. Management, vol. 62, no. 2, Aug. 1, 1921, pp. 109–113, 3 figs. How they concern production.

Charts. Managing an Industry by Graphic Charts, Arthur T. Burnet. Management Eng., vol. 1, no. 2, Aug. 1921, pp. 83–87, 2 figs. Typical charts and their use. How current facts are quickly and economically supplied to executive.

Standardizing the "Z" Chart, Arthur R. Burnet. Management Eng., vol. 1, no. 3, Sept. 1921, pp. 153–158, 4 figs. Discusses standardizing type of management engineering chart known as the "Z" chart to permit of its production in quantity.

The Ratio Chart and Its Application—II and III, Percy A. Bivins. Indus. Management, vol. 62, nos. 2 and 3, Aug. 1 and Sept. 1, 1921, pp. 99–104 and 166–171, 19 figs. Based on memo notes of an office manual for guidance of draftsmen unfamiliar with ratio plotting. Advantages and disadvantages of ratio charts compared with charts on arithmetic basis.

[See also GANTT CHARTS.]

Efficiency. The Final Measure of Industrial Efficiency, A. L. DeLeeuw. Management Eng., vol. 1, no. 3, Sept. 1921, pp. 141–146, 1 fig. Notes on how to obtain maximum efficiency. Consideration of equipment and plant efficiency. Influence of capital charges. An application of index numbers.

Engineering Students, Training in. Existing Courses in Management Engineering, Collins P. Bliss. Management Eng., vol. 1, no. 1, July 1921, pp. 43–48, 1 fig. Gives make-up of eight courses and time allotted to each general group of subjects and to each study. Summary and chart showing number of hours devoted to individual subjects.

Gantt Charts. The Gantt Chart, Wallace Clark. Management Eng., vol. 1, nos. 2 and 3, Aug. and Sept., 1921, pp. 77–82, 9 figs., and 161–166, 6 figs. Advantages, principle, technique and application to man records and layouts.

Inspection. Inspection. Mech. Wld., vol. 52, 1806, August 12, 1921, pp. 118–119, 5 figs. Discusses necessity for inspection and the tact required by an inspector.

Marketing. The Elimination of Waste in Marketing, William R. Basset. Chem. & Metallurgical Eng., vol. 25, no. 9, Aug. 31, 1921, pp. 420–422. States that marketing from point of view of manufacturer can be made more profitable by application of better methods of distribution and by establishment of improved selling policies.

Material Specifications. Material Specifications, E. A. Allcut. Eng. & Ind. Management, vol. 6, no. 5, August 4, 1921, pp. 114–115. Emphasizes necessity for complete specifications of materials in case of small users.

Overtime, Influence of. The Influence of Overtime on Costs, B. C. Sloat. Management Eng., vol. 1, no. 1, July 1921, pp. 9–10. Wage costs and shop maintenance as influenced by overtime; effect on shop morale and on workmanship.

Planning. Precalculation in the Factory (Aufgaben einer Betriebsvorkalkulation), Paul Bischoff. Werkstattstechnik, vol. 15, no. 15, Aug. 1, 1921, pp. 448–450, 5 figs. Points out advantages of predetermination of time required for finishing a workpiece.

Production Control. Production Control. P. J. Darlington. Indus. Management, vol. 62, no. 2, Aug. 1, 1921, pp. 95–98, 2 figs. Its strong and weak points. Author sets forth purposes and requirements and emphasizes permanent management's vital relationship to system.

Production, Economics of. The Economics of Production—III, D. A. McCabe. Am. Mach., vol. 55, no. 10, Sept. 8, 1921, pp. 381–382. Costs and price and production.

Production Increase. Accumulative Skill As a Factor in Production, Hugo Diemer. Management Eng., vol. 1, no. 2, Aug. 1921, pp. 111–112. Proof that group experience and pride in work increase output.

Scientific Management—XXIX, Henry Atkinson. Eng. & Indus. Management, vol. 6, no. 4, July 28, 1921, pp. 97–98. Incentives to economical production.

Six Ways of Increasing Production, G. D. Halsey. Management Eng., vol. 1, no. 2, Aug. 1921, pp. 97–98. (1) Introduction of labor-saving machinery; (2) specialization; (3) aggregation (combination with any other department); (4) standardization of parts; (5) elimination of wastes of materials; and (6) increasing individual efficiency.

Program for. What is Management in Industry? C. E. Knoeppel. Management Eng., vol. 1, no. 1, July 1921, pp. 23–28, 1 fig. Placing blame and fixing responsibility. A program for management.

Routing. Cutting Out Waste in the Shop. Elec. Ry. Jl., vol. 58, no. 6, August 6, 1921, pp. 193–198, 24 figs. Discusses minimizing of lifting operations, effective routing of machine jobs and permanent repair of defective parts.

The Group System of Process Planning, W. J. Hiscox. Machinery, (Lond.), vol. 18, no. 464, August 18, 1921, pp. 600–601. Discusses routing of jobs through the shop.

Small Factories. Management Problems of the Small Factory, Ernest Cordeal. Indus. Management, vol. 62, nos. 2 and 3, Aug. 1 and Sept. 1, 1921, pp. 114–119 and 182–187, 4 figs. Aug.: Costs and their use. Sept.: Supervision and inspection.

Storeskeeping. The Essentials of Storeskeeping, Wallace Clark and C. E. Davies. Management Eng., vol. 1, no. 1, July 1921, pp. 11–16, 9 figs. Notes on storeskeeper's responsibilities; marking the order points; keeping records of stock; safeguarding stores; disposing of unneeded material; and selection and training of personnel.

Production and the Stores Department, H. G. Harley. Eng. Production, vol. 3, no. 46, Aug. 18, 1921, pp. 150–154, 12 figs. Describes combined production and stock-recording system.

Woodworking Shops. Production Control in Wood-Working Shops, F. B. Sampson. Wood-Worker, vol. 40, no. 6, August 1921, pp. 30–32, 8 figs. Outline of fundamentals of production control. Gives time allowance and operations layout charts.

[See also FATIGUE; TIME STUDY.]

INDUSTRIAL ORGANIZATION

Large Contract Plants. Organization of Large Contract Plants, George H. Shepard. Machy. (N. Y.), vol. 27, no. 12, Aug. 1921, pp. 1100–1103, 3 figs. Deals with organization of plants making variety of products, and establishment of planning, dispatching, and recording systems.

Small Shops. Organization and Management of the Small Shop—IV, E. W. Leach. Am. Mach., vol. 55, no. 9, Sept. 1, 1921, pp. 338–341. Financing company; coöperating with investor; advantages and disadvantages of partnerships and corporations.

INDUSTRIAL RELATIONS.

Americanization. Industrial Americanization, Luther D. Burlingame. Machy. (N. Y.), vol. 28, no. 1, Sept. 1921, pp. 30–32. Policy of Brown & Sharpe Mfg. Co. in assisting alien employees to become American citizens.

Human Elements in. Human Elements in Engineering, J. J. Flather. Bul. Minn. Federation Architectural & Eng. Societies, vol. 6, no. 7, July 1921, pp. 21–32. Discusses hours of work, pleasant surroundings, etc. and their influence on production. Lays stress on the point that philanthropy has no part in industrial management.

INDUSTRIAL TRUCKS

Lifting. The Edgar Brandt Elevator-Truck (Le Chariot élévateur Edgar Brandt), M. d'About. La Vie Automobile, vol. 17, no. 735, August 10, 1921, pp. 285–286, 2 figs. Description of hand-operated truck for loading and unloading boxes up to 400 kg. into and from delivery wagons.

INDUSTRY

Arbitration Courts. Wastes in Litigation, Wellington Gustin. Chem. & Metallurgical Eng., vol. 25, no. 9, Aug. 31, 1921, pp. 423–427. Losses arising from litigation said to be potential factor in success or failure of any industry or business. Lack of knowledge of technical terms and standards on part of courts a strong argument for establishment of arbitration courts within industry.

INTERNAL-COMBUSTION ENGINES

Adapting to Rarefied Atmospheres. Adapting Explosion Engines to Rarefied Atmospheres (Le Problème de l'Adaptation des Moteurs a Explosions aux Atmosphères Raréfiées). L'Aeronautique, vol. 1, no. 9, February 1920, pp. 399–402, 6 figs. Reduces all methods to form fundamental ones and discusses these.

Cycle Evaluating Chart. A Nomographic Chart for Gases, T. B. Morley. Engineering, vol. 112, no. 2904, Aug. 26, 1921, pp. 302–304, 5 figs. Chart developed by author for evaluating with ease and rapidity internal-combustion-engine cycles, which yields approximate results, claimed to be preferable to "air standard" values.

Exhaust-Gas Analysis. A Further Application of Diagrams to the Analysis of Exhaust Gases (Eine weitere Anwendung von Schaubildern zur Abgasanalyse), K. Kutzner. Zeit. des Vereines deutscher Ingenieure, vol. 65, no. 33, Aug. 13, 1921, pp. 871–873, 1 fig. Chart is developed for simple determination of that part of carbon content of coal which is not consumed in combustion. Use of chart, employed by Neufeldt & Kuhnke, Kiel, for testing hot-bulb motors, is described with aid of examples.

Installation. Practical Notes on the Installation and Running of Petrol, Petrol-Paraffin, and Semi-Diesel Engines, D. P. Lamb. Mech. Wld., vol. 70, no. 1804, July 29, 1921, pp. 91–92. Discusses reverse gear, exhaust pipe, circulating pumps, gear pumps and fuel-supply system. (To be continued.)

Large-Cylinder. Internal Combustion Engines with Large Cylinders, James McKechnie. Gas & Oil Power, vol. 16, no. 191, August 4, 1921, pp. 173–174. Discusses requirements of mercantile ships, electric drive, two-stroke design, and gives table of test data of 1000-b.hp. single-cylinder engine. From paper read before Instn. Civil Engrs.

Operation. Practical Notes on the Installation and Running of Petrol, Petrol-Paraffin, and Semi-Diesel Engines, D. P. Lamb. Mech. Wld., vol. 52, no. 1805, August 5, 1921, pp. 112–115. Discusses carbureters, lubrication, magnetos, water circulation.

Vegetable Oils for. Vegetable Oils for Internal Combustion Engines, R. E. Mathot. Engineer, vol. 132, no. 3423, Aug. 5, 1921, pp. 138–139. Author gives results of his investigations and makes suggestions for improvements in design of engines to fill requirements of colonial service.

[See also AEROPLANE ENGINES; AUTOMOBILE ENGINES; DIESEL ENGINES; OIL ENGINES; SEMI-DIESEL ENGINES.]

IRON

Foundry. Foundry Irons for Particular Uses, Y. A. Dyer. Iron Age, vol. 108, no. 10, Sept. 8, 1921, pp. 585–588. Differentiating characteristics of gray iron, mottled, chilled or white. Analyses of certain castings.

IRON ALLOYS

Iron-Nickel. Making a 5-per cent. Nickel-cast-iron Alloy in an Electric Furnace, D. N. Witman. Trans. Am. Inst. Min. & Met. Engrs., no. 1087-S, August 1921, 4 pp., 1 fig. Discusses different alloys used for production of electrical-resistance grids.

Iron-Silicon System. On the Equilibrium Diagram of Iron-Silicon System, Takejiro Murakami. Science Reports Tôhoku Imperial Univ., vol. 10, no. 2, June 1921, pp. 79–92, 26 figs. Description of experiments carried out resulting in a revision of the equilibrium diagram by Guertler and Tammann.

IRON CASTINGS

Chill Castings. Chill Castings (Le Moulage en Coquille), A. Dat. Arts et Métiers, vol. 74, no. 9, June 1921, pp. 167–170, 11 figs. Discusses making of mold, pouring under pressure, etc.

Nickel and Cobalt in. Nickel and Cobalt in Iron, O. Bauer and E. Piwowarsky. Iron Age, vol. 108, no. 9, Sept. 1, 1921, p. 513. German experiments on iron castings; nickel improves physical properties. Translated from Stahl u. Eisen, Sept. 30, 1920.

IRON INDUSTRY

Brazil. Historical Data on the Brazilian Iron Industry (Några blad ur den brasilianska järnhandteringens historia), Harald Carlborg. Jerkontorets Annaler, vol. 105, no. 3, 1921, pp. 125–143. Contains also data on recent smelting practice.

L

LABOR

Hours of Work and Output. Hours of Work and Output. Eng. & Ind. Management, vol. 6, no. 5, August 4, 1921, pp. 122–124. Annual report of British Chief Inspector of factories and workshops.

Loss, Sources of. The Sources of Labor Loss, J. Burk LeClere. Indus. Management, vol. 62, no. 3. Sept. 1, 1921, pp. 177–181. How they affect production through man power.

LABOR TURNOVER

Accidents In Relation to. The Unexpected Trend in Accident Prevention, C. B. Auel. Management Eng., vol. 1, no. 1, July 1921, pp. 35–41, 2 figs. Long service, good health, contentment, cleanliness, and carefulness are said to be more important than mechanical devices.

LATHES

Automatic. The Barker Two Period Alternating Automatic. Eng. Production, vol. 3, no. 45, August 11, 1921, pp. 124–125, 4 figs. Description of four spindle automatic lathe for bar work constructed by The Victor Engineering Co., Ltd., Glasgow, Eng.

LIGHTING

Canneries. Solving Special Lighting Problems in the Modern Cannery, Warren Alden. Jl. Elec. & Western Ind., vol. 47, no. 4, August 15, 1921, pp. 145, 1 fig. Describes illumination in plant of Pratt-Low Preserving Co., Santa Clara, Cal.

Industrial. Elimination of Waste in Industry Due to Poor Lighting, Ward Harrison. Chem. & Metallurgical Eng., vol. 25, no. 9, Aug. 31, 1921, pp. 407–409, 6 figs. Points out importance of installation and proper maintenance of adequate illumination in avoidance of industrial accidents and resulting wastes of man power, losses of time, materials and production.

LIGNITE

Briquetting. The Economy of Briquetting (Die Wirtschaftlichkeit der Briketterzeugung), Otto Schöne. Braunkohle, vol. 19, nos. 50 and 51, Mar. 22 and 29, 1921, pp. 632–638 and 651–652, 2 figs. Writer demonstrates that in a properly equipped lignite briquet factory the actual loss through briquetting amounts to only 7.7 per cent.

The Loss of Fuel Through the Briquetting of Lignite (Der Brennstoffverlust durch die Brikettierung der Braunkohle), H. Berner. Zeit. für Dampfkessel u. Maschinenbetrieb, vol. 44, nos. 14 and 16, Apr. 8 and 15, 1921, pp. 108–110 and 116–117. Report of the expert committee of the Lignite Syndicate, showing that the original consumption of fuel in briquet factories amounting to 17 to 31 per cent represents an actual loss of only 8 per cent.

LOCOMOBILES

Robey. A 500-Horse-power Combined Engine and Boiler. Engineer, vol. 132, no. 3421, July 22, 1921, p. 88, 9 figs. on supp. plate and p. 94. Plant built by Robey & Co., Ltd., London, consists of compound engine mounted over circular boiler, having circular furnace and tubes which are withdrawable, and is provided with a superheater in smoke-box and a feedwater heater.

LOCOMOTIVE BOILERS

Tubes. Steel vs. Brass Locomotive Boiler Tubes. (Le Tube de Chaudière de Locomotive acier ou laiton?), O. Hock. Revue Universelle des Mines. vol. 10, no. 3, August 1, 1921, pp. 261–269. Discusses experiences in various countries and shows that steel tubes are more economical.

LOCOMOTIVES

4-8-0. New 4-8-0 Type Locomotives for the Jamaica Government Railways. Ry. Gaz., vol. 35, no. 6, August 5, 1921, pp. 249–250, 3 figs. These engines were specially designed to work various classes of traffic on hilly sections of main line where heavy and long grades occur, with many curves of small radius.

Oil-Burning. Liquid-Fuel Burning Locomotives on British Railways—I. Ry. Engr., vol. 42, no. 499, August 1921, pp. 304–310, 11 figs. Describes recent developments with various companies. (To be concluded.)

Poppet-Valve Gear. A New Type of Poppet-Valve Gear in the Consolidation Locomotive no. 740. 324 F.S. (Su di un nuovo tipo di distribuzione a valvole applicato sulla locomotiva "Consolidation" no. 740.324 F.S.), Guido Corbellini. Rivista Tecnica delle Ferrovie Italiane, vol. 19, no. 6, June 15, 1921, pp. 152–170, 13 figs. Description of Caprotti type, and theoretical results expected from it. (To be continued.)

Shop Practice. Methods Employed in the Locomotive Shops of the Great Western Railway Co., Swindon—VII. Machinery (Lond.), vol. 18, no. 461, July 28, 1921, pp. 497–502, 16 figs. Discusses piston rings, piston crossheads, slippers, guidebars, etc.

Superheater, Oil-Fired. New Baldwin Locomotives For Cuba. Ry. Gaz., vol. 35, no. 8, August 19, 1921, pp. 315–316, 3 figs. Describes 0-8-0 shunting tank engine, 2-8-0 freight engine and 4-6-2 passenger locomotive, with superheater boilers and liquid-fuel-burning apparatus.

Western Railway. Ry. Engr., vol. 12, no. [illegible] August 1921, pp. 285–288, 7 figs. Capable of exerting a tractive force of 34,000 lb., at 85 per cent of boiler pressure.

Tires, Machining. Tools for Boring and Turning Locomotive Tires—II, Fred H. Colvin. Am. Mach., vol. 55, no. 8, Aug. 25, 1921, pp. 313–317, 21 figs. Rough and finish turning tools. Solid tools and tools in holders. Angles of rake and clearance are said to vary greatly in different shops.

Winterthur Type. The New Locomotive of the Sumatra State Railway [Die neue Lokomotiven der Staatsbahnen auf Sumatra (Westküste)]. Siegfried Abt. Schweizerische Bauzeitung, vol. 77, no. 7, Aug. 13, 1921, pp. 75–77, 5 figs. Specifications of Winterthur-type 0-D-1 wet-steam and 0-E-0 superheated-steam compound locomotives: Gage, 1067 mm.; cylinder bore, 450 mm.; piston stroke, 480 and 520 mm. respectively; wheelbase, 6.4 and 5 m. respectively; total heating surface, 103.2 and 102.36 sq.m. respectively; coal supply, 1200 kg.; weight empty, 38.54 and 41.92 tons respectively.

LUBRICANTS

Friction. The Theory of the Friction of Lubricants (Zur Theorie der Schmiermittelreibung), A. Sommerfeld. Zeit. für technische Physik, vol. 2, nos. 3 and 4, 1921, pp. 58–63 and 89–93, 6 figs. No. 3: Notes on dry and liquid friction; tests of the law of similarity. No. 4: Fundamental principles and quantitative results of the hydrodynamic theory of lubricants. Report of work by Lord Rayleigh.

LUBRICATING OILS

Specifications. Lubricating Oil Temperature Charts. Gas Age-Rec., vol. 48, no. 5, August 20, 1921, pp. 201–202, 2 figs. Show effect of viscosity on lubricating oils; gives specifications for selecting oils.

M

MACHINE DESIGN

Errors, Causes of. Common Causes of Errors in Machine Design, R. H. McMinn. Machy. (N. Y.), vol. 28, no. 1, Sept. 1921, pp. 38–39. Instructions and standards. Convenient form for data. Attitude toward errors. (Concluded.)

MACHINE GUNS

Barrels, Life of. Some Factors Affecting the Life of Machine-Gun Barrels, W. W. Sveshnikoff. Dept. Commerce, Technologic Papers Bur. Stand. no. 191, June 4, 1921, 27 pp., 19 figs. Results of experiments show that deterioration is due to combination of abrasive action of bullet and abrasion by hot gases.

MACHINE SHOPS

British. The Works of Messrs. Edgar Allen and Co., Limited, Sheffield. Engineering, vol. 112, nos. 2903, 2904 and 2905, Aug. 19, 26 and Sept. 2, 1921, pp. 272–274, 304–307 and 335–338, 32 figs. partly on supp. plates. Describes plant for making of manganese steel, tool steel, files, circular saws, twist drills, steel castings, railway and tramway special track work, crushing and grinding machinery, cement and powdered fuel plant, etc.

Famous British Works. Eng. Production, vol. 3, no. 45, August 11, 1921, pp. 122–123, 1 fig. Description of Rolls-Royce, plant at Derby, Automobile manufacturers.

Famous British Works. Eng. Production, vol. 3, no. 46, Aug. 18, 1921, pp. 146–149, 5 figs. Details of machine-tool works of Alfred Herbert, Ltd., Coventry.

Famous British Works. Eng. Production, vol. 3, no. 47, Aug. 25, 1921, pp. 170–172, 4 figs. Details of works of Robey & Co., Ltd., Lincoln, for manufacture of agricultural machinery, steam wagons, and all kinds of engines, including uniflow and semi-Diesel engines, air compressors, etc.

MACHINE TOOLS

Manufacture. Well House Foundry, Leeds. Engineer, vol. 132, no. 3424, Aug. 12, 1921, pp. 166–168, 11 figs. partly on pp. 164 and 170. Plant for construction of heavy machine tools and testing machines. Details of the different shops and some of machines constructed.

MACHINERY

Vibration. Elimination of Machine Vibration. Indian Industry & Power, vol. 18, no. 10, June 1921, pp. 529–531, 5 figs. Explains origin of vibrations and shows how to overcome them.

MALLEABLE IRON

American Foundry Practice. American Malleable Cast Iron—XIV–XVIII, H. A. Schwartz. Iron Trade Rev., vol. 69, nos. 2, 4, 6, 8 and 10, July 14, 28, Aug. 11, 25 and Sept. 8, 1921, pp. 98–101, 2 figs., 233–238, 8 figs., 354–359, 4 figs., 496–499, 3 figs., and 611–616, 9 figs. July 14: Cupola and open-hearth melting. July 28: Annealing practice. Aug. 11: Metallurgy of annealing. Aug. 25: Pattern-making and molding. Sept. 8: Cleaning and finishing.

MANUFACTURING

Special Tools vs. Standard Equipment. Manufacturing With Special Machines vs. Standard Equipment—IV, F. Jenks and M. H. Christopherson. Am. Mach., vol. 55, no. 9, Sept. 1, 1921, pp. 349–353, 13 figs. Portable devices for plain and thread milling. An angular drilling fixture. Special machine for milling sinuous oil grooves.

MARINE STEAM TURBINES

Geared. Geared Marine Turbines, C. R. Waller. Am. Mar. Engr., vol. 16, no. 10, May 1921, pp. 11–13, Steam Turbine Co.

MATERIAL HANDLING

Modern Methods. The Moving of Materials in Industry, R. M. Gates. Management Eng., vol. 1, no. 2, Aug. 1921, pp. 65–70, 9 figs. Suggestions for better and greater application of mechanical material-moving devices.

MATERIALS

Testing. Material Testing in the German Material-Testing Bureau (Materialprüfung im Staatlichen Materialprüfungsamt). Zeit. für Dampfkessel u. Maschinenbetrieb, vol. 44, nos. 12, 13 and 16, Mar. 25, Apr. 1 and 22, 1921, pp. 93–94, 101 and 124–125. (Abstract.) Report of State Material-Testing Bureau, Berlin-Lichterfelde, on work carried out in 1919–20.

MATTER

Changes of Form. Crystals, Solids and Vitreous Matter, A. Portevin. Sci. Am. Monthly, vol. 4, no. 2, Aug. 1921, pp. 137–141, 6 figs. Basic principles and general phenomena relating to changes of form in matter. Translated from La Revue de l'Ingénieur, April 1921.

MEASURING INSTRUMENTS

Electric Sensitive. Sensitive Measuring Apparatus, J. B. Moran. Machy. (N. Y.), vol. 28, no. 1, Sept. 1921, pp. 36–37, 2 figs. Describes electrical measuring device which is sensitive to one two-hundred millionths of an inch.

METAL SPRAYING

Meurer-Hopfelt Process. Metal-Spraying Machines (Die Metallspritzmaschine), M. Meurer. Autogene Metallbearbeitung, vol. 14, no. 11, June 1, 1921, pp. 159–166, 6 figs. Describes two types of the Meurer-Hopfelt machines, the one, used for cleaning as well as metallization, operates without heating of parts; the other, for metallization only, requires heating of metallizing drum and preheating of workpieces.

METALS

Calorizing. Protection of Metals by Calorizing (La Protection des Metaux Par la Calorisation). Le Génie Civil, vol. 79, no. 6, August 6, 1921, pp. 131–132, 3 figs. Discusses principles, advantages and difficulties of process.

MILLING MACHINES

Pressures Exerted by Cutters. Determining Pressures Exerted by Cutters. Can. Machy., vol. 26, no. 4, July 28, 1921, pp. 33 and 35, 3 figs. Describes device indicating pressures exerted on various parts of milling machine.

MINE HAULAGE

Rope Testing. Testing Rope and Driving Pulleys During Inspection Journey on the Volkenroda and Pöthen Potash Mines (Prüfung von Seil- und Treibscheibe während der Betriebsfahrt auf den Kalizechen Volkenroda und Pöthen), E. Jahnke and W. Heilmann. Kali, vol. 15, no. 14, July 15, 1921, pp. 229–231, 8 figs. Results of measurements made in March 1921, are shown in diagrams.

MINE HOISTING

Electric. Determination of Electrical Equipment for a Mine Hoist, Graham Bright. Min. & Metallurgy, no. 177, Sept. 1921, pp. 49–50. Discusses hoist calculation methods and selection of proper type of electrical equipment. (Abstract.) Paper read before Am. Inst. Min. & Metallurgical Engrs.

Electric Winding: Its Advantages and Economy A. B. MacLean. Mech. Wld., vol. 52, no. 1807, August 19, 1921, pp. 149–150. Discusses two cases in which cost of steam winding has been accurately obtained and wherein the steam conditions are typical of the locality. Abstract paper read before Assn. Min. Elec. Engrs.

Koepe Sheave. A Special Method of Replacing the Rope on a Koepe Sheave (Ein besonderes Verfahren des Auswechselns eines Koepe-Seils), A. Noack. Berghau, vol. 34, no. 23, June 9, 1921, pp. 651–654, 2 figs. Describes method which can be employed with aid of steam cable and friction-gear winches, the only machine equipment required being the hauling engine and a small hand winch.

Rope Joints and Clamps. Rope Joints and Clamps (Seilverbindungen und Seilklammern), Karl Micksch. Bergbau, vol. 34, no. 24, June 16, 1921, pp. 685–688, 14 figs. Discusses various types.

MOLYBDENUM STEEL

Uses. Molybdenum Steel Uses Increase, M. H. Schmid. Iron Trade Rev., vol. 69, no. 9, Sept. 1, 1921, pp. 559–561. Use in manufacture of automobiles and other applications. Tests show properties of various alloys. (Abstract.) Paper presented before Am. Soc. for Steel Treating.

MONEL METAL

Impact Tests. Note on Notched Bar Impact Tests and Toughness of Monel Metal, R. G. Waltenberg, Chem. & Met. Eng., vol. 25, no. 8, August 24, 1921, pp. 322–323. Gives details of Charpy and Izod tests.

MOTOR BUSES

Railway-Track. Motor Omnibus For Railway Service. Tramway & Ry. Wld., vol. 50, no. 9, August 18, 1921, pp. 70–71, 4 figs. Built by J. G. Brill Co. for Chesapeake Western R. R. Is a one-man bus.

MOTOR-TRUCK TRANSPORTATION

Comparison with Railways. The Motor Truck and the Railroad, Rollin W. Hutchinson. Indus. Management, vol. 62, no. 3, Sept. 1, 1921, pp. 131– [illegible]

MOTOR TRUCKS

English. A Remarkable New Transport Vehicle. Motor Transport, vol. 33, no. 860, August 22, 1921, pp. 200–201, 2 figs. Describes a transport truck made by Haulage Improvements & Constructions, Ltd., Lond.

Steam. The Clarkson Steam Lorry. Engineering, vol. 112, no. 2903, Aug. 19, 1921, pp. 275–278, 12 figs. New type of vehicle which burns coke. Details of engine, boiler, etc.

N

NITROGEN

Fixation. Commercial Production of Atmospheric Nitrogen, by the Flaming Electric Arc (Lo Sfruttamento Industriale dell'Azoto Atmosferico, per Mezzo dell'Arco Elettrico a Fiamma). Il Forno Elettrico, vol. 3, no. 4, April 15, 1921, pp. 51–56, 3 figs. Describes arrangement using high-tension a.c. and d.c. electromagnet. (Concluded.)

Supplementary Report on Nitrogen Products. Chem. Age, vol. 5, no. 112, August 6, 1921, pp. 148–151. Discusses progress of fixation of nitrogen in various countries.

Recovery by Activated Sludge Process. Nitrogen—with Special Reference to Activated Sludge, Gilbert J. Fowler. Eng. News-Rec., vol. 87, no. 8, Aug. 25, 1921, p. 311. (Abstract.) Monograph entitled The Conservation of Nitrogen with Special Reference to Activated Sludge, comprising Dec. issue of Jl. Inst. of Sci., Bangalore, India.

O

OIL ENGINES

Double-Acting Two-Stroke Marine. The First Motor Ship with Double-Acting Two-Stroke Engines, R. Dreves. Engineer, vol. 132, no. 3425, Aug. 19, 1921, pp. 191–192, 1 fig. Describes engines installed on twin-screw cargo vessel, Fritz, having three working cylinders of 480 mm. diam. and 710 mm. stroke, and developing 830 brake hp. at 120 r.p.m. Account of trial trips with ship which was delivered to England in November 1919, according to terms of Peace Treaty.

Marine. Some Observations on Marine Oil Engines, D. M. Shannon. Mech. Wld., vol. 52, no. 1807, August 19, 1921, pp. 143–144, 11 figs. Discusses Diesel and hot-bulb engines. (To be continued.) From paper read before Inst. Mar. Engrs.

Opportunity of. Waste of Coal and Oil Fuel. Gas & Oil Power, vol. 16, no. 191, August 4, 1921, pp. 165–167, 2 figs. Discusses opportunity of the small oil and the Diesel engine.

OIL FIELDS

Mexico. Mexican Oil Fields, L. G. Huntley and Stirling Huntley. Min. & Metallurgy, no. 177, Sept. 1921, pp. 27–32, 3 figs. Survey of producing, areas, known reserves, and geological factors which point to important development.

OIL SHALES

Esthonia. The Oil Shales in Esthonia (Ueber die Oelschiefer in Estland), C. Gäbert. Braunkohle, vol. 19, nos. 48 and 49, Mar. 12 and 17, 1921, pp. 597–610 and 613–625, 26 figs. partly on supp. plate. Large stretches of bituminous shales occur in slight depths in the rock foundations of Esthonia. Bibliography. General geological and topographical conditions. Chemical and technical conditions.

Rocky Mountains. Notes on the Oil-Shale Industry With Particular Reference to the Rocky Mountain District, M. J. Gavin, H. H. Hill and W. E. Perdew. Reports of Investigations Dept. of Interior Bur. of Mines, Serial no. 2256, June 1921, 36 pp., 2 figs. Discusses mining, retorting, refining in Scotland and in U. S.

Thermal Decomposition. The Thermal Decomposition of Oil Shales—II, Ralph H. McKee and E. E. Lyder. Jl. Ind. & Eng. Chem., vol. 13, no. 8, August 1921, pp. 678–684, 3 figs. Determination of heat of reaction involved in their thermal decomposition. Results of experiments show that decomposition takes place between 400 and 410 deg. cent.

OIL WELLS

Production. Some Principles Governing the Production of Oil Wells, Carl H. Beal and J. O. Lewis. Petroleum Times, vol. 6, no. 135, August 6, 1921, pp. 183–185. Discusses natural and artificial influences in yield of wells. (To be continued.)

OILS

Soy-Bean. Soy-Bean Oil: Factors Which Influence Its Production and Composition, Carl R. Fellers. Jl. Ind. & Eng. Chem., vol. 13, no. 8, August 1921, pp. 689–691. Discusses physical and chemical properties, oil and protein content, and effect of planting date on composition.

OPEN-HEARTH FURNACES

Gas-Fired. The Heating of Open-Hearth Furnaces with a Mixture of Lignite-Briquet and Blast-Furnace Gas (Die Beheizung von Martinöfen mit einem Gemisch von Braunkohlenbrikett- und Hochofengas), Fritz Boettcher. Stahl u. Eisen, vol. 41, no. 30, July 28, 1921, pp. 1027–1030, 4 figs. It is shown that smelting with such mixture is possible under given conditions. The producer must be operated

as slowly and as cold as possible, and the furnaces must permit of transmission of larger quantities of gas through furnace space with greater speed.

OXY-ACETYLENE CUTTING

Radiograph and Oxygraph Machines. Oxy-Acetylene Cutting Machines. Engineering, vol. 112, nos. 2903, 2904 and 2905, Aug. 19, 26 and Sept. 2, 1921, pp. 274–275, 307–311 and 356–357, 30 figs. Constructed by Davis-Bournonville Co., Jersey City N. J. Aug. 19: Details of the radiograph machine for cutting metal up to 20 or 22 in. thick in straight lines or to circular profiles. Aug. 26 and Sept. 2: The oxygraph machines nos. 1A and 2A.

P

PAINTS

White Lead. White Lead in Painting. Engineering, vol. 112, no. 2904, Aug. 26, 1921, pp. 323–324. Outline of statement issued by London Chamber of Commerce entitled Case Against Prohibition, in connection with subject to be discussed at Int. Labor Conference at Geneva, Oct. 25 on the prohibition of use of white lead in painting.

PATENT LAWS

Needed Improvements. The Patent Situation, Edwin J. Prindle. Chem. & Metallurgical Eng., vol. 25, no. 9, Aug. 31, 1921, pp. 417–419. Claims that inadequate salaries and insufficient personnel are causes of waste in patent office for which industry must pay in costly delays and burdensome litigation. Analysis of legislation designed to remedy situation.

PEAT

Production and Refinement. New Methods and Future Problems in the Peat Industry (Neue Wege und Zukunftsaufgaben der Torfindustrie), H. R. Trenkler. Feuerungstechnik, vol. 9, no. 20, July 15, 1921, pp. 185–186. Discussion of modern processes for recovery and refinement of peat, based on papers by Karl Birk presented before Soc. for Promotion of Moor Coal Cultivation.

PETROLEUM

Distillation. Mineral Oil Distillation. Petroleum Wld., vol. 18, no. 251, August 1921, pp. 313–320, 4 figs. Discusses questions of dephlegmation and preheating. (To be continued.)

Galicia. Galician Oil (Il Petrolio Galiziano), L. Maddalena. Revista Tecnica delle Ferrovie Italiane, vol. 19, no. 6, June 15, 1921, pp. 171–180, 2 figs. Discusses geology and resources, conditions of industry, and Italian interests in Galician oil.

Refining. Minimizing Heat Losses in Oil Refining. Min. & Oil Bul., vol. 7, no. 9, August 1921, pp. 537–539 and 563, 4 figs. Discusses high-temperature heat insulators as applied to various stills.

The Refining of Petroleum, C. K. Francis. Min. & Oil Bul., vol. 7, no. 9, August 1921, pp. 524–528 and 563, 2 figs. Discusses fractional distillation, gasoline, naphtha, lubricating oils, wax, petrolatum, etc.

PHOTOMETERS

Reflectometers. The Ball Photometer as Reflectometer (Das Kugelphotometer als Reflektometer), R. Ulbricht. Zeit. für Beleuchtungswesen, vol. 27, no. 13–14, July 15–31, 1921, pp. 51–54, 3 figs. Notes on Taylor's portable reflectometer described in Elec. World (Sept. 4, 1920, p. 467), and author's own work, entitled the ball photometer, published by R. Oldenbourg, Münich and Berlin.

PIPE

Flange Joints. Jointing Material for Pipe Flanges (Etwas über Flanschen-Dichtungsmaterial). Elektrotechnischer Anzeiger, vol. 38, no. 93, June 14, 1921, pp. 627–630. Deals with different kinds of jointings for pipe flanges for steam and gases of high and low pressure and different temperatures, as well as for such liquids as water, oil, tar, acids, alkalis, etc.

PIPE LINES

Wood-Stave. Wood Pipe Lines in New England Hydroelectric Development. Elec. Rev. (Chicago), vol. 79, no. 8, August 20, 1921, pp. 265–268, 8 figs. Also in Eng. Wld., vol. 19, no. 2, Aug. 1921, pp. 77–80, 8 figs. Some data on recent wood-stave construction.

PISTONS

Light-Metal. Light Metal Pistons for Engines (Leichtmetallkolben für Motoren), R. Krüger. Oel- u. Gasmaschine, vol. 18, no. 7, July 1921, pp. 105–110, 7 figs. Notes on material, manufacture and life of aluminum pistons; pressing and casting processes; Dow-metal pistons.

Machining. Machining One Hundred Engine Pistons per Hour, J. H. Moore. Can. Machy., vol. 26, no. 6, August 11, 1921, pp. 25–27, 12 figs. Examples of work produced including valve stem guide, engine valve cage, etc.

PLANERS

Mechanical Reversing Drive. A Mechanical Reversing Drive for Planing Machines. Engineer, vol. 132, no. 3422, July 29, 1921, pp. 124–125, 3 figs. Details of the Newton-Derby patented reversing drive.

Newton Planer Reversing Drive. Machinery (Lond.), vol. 18, no. 461, July 28, 1921, pp. 515–517, 4 figs. Application of epicyclic reduction gearing.

POWER PLANTS

Developments. Developments in Power Station Design—V. Engineer, vol. 132, no. 3425, Aug. 19, 1921, pp. 190–191, 4 figs. Details of the Bettington boiler arranged for burning pulverized coal, constructed by Fraser & Chalmers, Ltd.

Hershey Chocolate Co. Hershey Chocolate Company's New Power Plant. Power, vol. 54, no. 4, July 26, 1921, pp. 124–131, 8 figs. Plant laid out for 7500 kw. at 80 per cent power factor, in four 2300-volt units, and ten water-tube boilers each having 7444 sq. ft. of heating service. Two 1250-kw. 80-per cent power-factor turbo generators and four boilers installed. Bleeder-type turbines are used and equipped with surface condensers.

Industrial. Industrial Power-Plant Data. Power, vol. 54, no. 4, July 26, 1921, pp. 139–140. Census figures from 26 states covering primary power in manufacturing establishments.

Seward, Pa. Power Plant Designed to Meet Conditions in Coal-Mining District, W. P. Gavit. Power, vol. 54, no 8, Aug. 23, 1921, pp. 278–286, 12 figs. Seward power station of Penn Public Service Corp. designed for 100,000 kw.; 40,000-kw. installed in two 20,000-kw. units. Boilers contain 16,000 sq. ft. of heat surface each. Automatic control of boiler operation.

PRECIPITATION

Electrical. Eliminating Waste and Nuisance in Smoke, Fume and Gas, P. E. Landolt. Chem. & Metallurgical Eng., vol. 25, no. 9, Aug. 31, 1921, pp. 428–432, 6 figs. Notes on electrical-precipitation methods in metallurgical, and chemical industries, and in other fields. Costs. Bibliography.

Extracting Flue Dust Electrically, N. H. Gellert. Iron Trade Rev., vol. 69, no. 2, July 14, 1921, pp. 102–105, 3 figs. Describes principle involved in precipitating dust by Cottrell process and method of operating an electrolytic cleaner. Comparison of various types of gas-cleaning equipment. (Abstract.) Paper presented before Assn. Iron & Steel Elec. Engrs.

PRESSES

Safeguarding. Safety Devices for Power Presses. Machy. (N. Y.), vol. 27, no. 12, Aug. 1921, pp. 1106–1109, and vol. 28, no. 1, Sept. 1921, pp. 40–42, 16 figs. Guards and safety measures provided for power-press equipment in Cleveland Metal Products Co.'s plant, Cleveland, Ohio.

PRESSWORK

Tools. An Interesting Press Job. Eng. Production, vol. 3, no. 47, Aug. 25, 1921, pp. 173–174, 10 figs. Tools for producing curtain holders.

PROFIT SHARING

British Plan. British Plan of Profit Sharing, T. Sington. Am. Gas Jl., vol. 115, no. 8, August 20, 1921, pp. 165–166. Discusses method adopted by gas companies.

PULVERIZED COAL

Advantages and Disadvantages. Pulverized Coal Firing (Allgemeines über Staubkohlenfeuerung), H. Richarz. Zeit. für Dampfkessel u. Maschinenbetrieb, vol. 44, no. 15, Apr. 15, 1921, pp. 113–116. Nature and useful scope, advantages and disadvantages. Bibliography. (Abstract.) Address before Soc. German Engrs.

Boiler Firing. Firing With Pulverized Coal (Le Chauffage au Charbon Pulvérisé), Paul Frion. Chaleur et Industrie, vol. 2, no. 15, July 1921, pp. 433–439. Discusses application of pulverized coal for furnaces and steam generator, also its drawbacks and dangers. (Concluded.)

Use of Pulverized Coal in Steam Power Plants, H. A. Reichenbach. Elec. Rev. (Chicago), vol. 79, no. 8, August 20, 1921, pp. 261–264, 5 figs. Method employed in handling and preparing fuel for delivery to furnace. Pipe line used to convey pulverized coal 1000 ft. Some tests results with anthracite silt and bituminous coal.

Work of the Commission For Fuel Utilization (Travaux de la Commission d'Utilisation des Combustibles), Paul Frion. Bulletin de la Société d'Encouragement pour L'Industrie Nationale, vol. 133, no. 5, May 1921, pp. 477–507. Report of third sub-committee. Firing with powdered coal. Report on investigation for and against use of powdered coal, recommending its use where suitable.

Gasification. A New Method for the Gasification of Pulverized Coal (Ein neues Verfahren zur Staubkohlenvergasung), K. M. Balley. Chemiker-Zeitung vol. 45, no. 99, Aug. 18, 1921, pp. 789–790, 2 figs. Describes method, its application and operation of plant.

Power Stations. Developments in Power Station Design. Engineer, vol. 132, nos. 3420, 3421, 3423 and 3424, July 15, 22, Aug. 5 and 12, 1921, pp. 70–71, 90–91, 142–144 and 162–163, 11 figs. Notes on by-products and waste heat, and pulverized coal. Different types of pulverized fuel plants, installed in English and American power plants.

Pulverizing Machine. The "Atritor" Coal Drying and Pulverizing Machine. Engineer, vol. 132, no. 3423, Aug. 5, 1921, p. 150, 1 fig. Details of new machine recently installed in cement works in Midlands, England. Advantages.

PUMPS, CENTRIFUGAL

Electrically Driven. Recent Installation of Centrifugal Pumps in Brockton Sewage Pumping Station, E. F. Leger. Am. City, vol. 25, no. 3, Sept. 1921, pp. 185–190, 2 figs. Transition from original pumping equipment of triple-expansion, steam-driven reciprocating pumps to electrically driven centrifugal pumps for pumping city sewage.

PYROMETERS

Optical. A Simple Optical Pyrometer (Ein einfaches optisches Pyrometer), H. Lux. Glasers Annalen für Gewerbe u. Bauwesen, vol. 89, no. 1, July 1, 1921, pp. 13–14, 2 figs. The Lummer-Kurlbaum pyrometer.

R

RAILS

Rerolling Discarded Steel. Rerolling Discarded Steel Rails, John D. Knox. Iron Trade Rev., vol. 69, no. 4, July 28, 1921, pp. 226–231, 10 figs. Practice as followed by Sweet's Steel Co. in preparing broken sections for mills. Description of plant.

RAILWAY ELECTRIFICATION

Advantages. The Electrification of Main Line Railways in Relation to Traffic Working, Philip Nash. Jl. Inst. of Transport, vol. 2, no. 5, March 1921, pp. 194–202 and (discussion) pp. 202–207. Discusses pros and cons of electricity and steam for freight haulage.

Germany. History of the Electrification of the Former Prussian-Hessian State Railways (Geschichte der elektrischen Zugförderung auf den ehemaligen preussisch-hessischen Staatseisenbahnen), Karl Trautvetter. Archiv für Eisenbahnwesen, nos. 3 and 4, May-June and July-Aug., 1921, pp. 582–595 and 793–812, 10 figs. History of development and progress since 1896.

RAILWAY MOTOR CARS

Gasoline. Petrol Rail Cars for India. Engineer, vol. 132, no. 3419, July 8, 1921, pp. 44–45, 5 figs. Describes 2-ft. 6-in.-gage 50-hp. petrol cars built for Kalka-Simla Railway by Drewry Car Co., Ltd., London.

RAILWAY OPERATION

Automatic Train Control. Problems of Automatic Train Control. Ry. Engr., vol. 42, no. 499, August 1921, pp. 311–315. Discusses various problems and cost of installation, principles of communication, etc.

Ceylon. The Ceylon Government Railways—II. Ry. Gaz., vol. 35, no. 6, August 5, 1921, pp. 257–258. Abstract from British government report on administration and working of railroad. (To be concluded.)

Economics. Economics of Railway Transport, and Methods of Raising Revenue, J. George Beharrell. Jl. Inst. of Transport, vol. 2, no. 5, March 1921, pp. 218–232, 7 figs. Discusses density of traffic, revenue and costs, rate-fixing machinery, commodity ton miles, etc.

Slow-Freight Traffic. On the Question of Slow Freight Traffic, U. Lamalle. Bul. International Ry. Assn., vol. 3, no. 7, July 1921, pp. 857–884, 10 figs. Discusses freight wagons, organization of train services, influence of rating on working capacity of rolling stock.

Trains over One-Way Divisions. The Operation of Trains over One-Way Divisions (Der Zuglauf bei Bahnen mit nur in einer Fahrrichtung benutzten Streckengleisen), H. Gaede. Archiv für Eisenbahnwesen, nos. 1, 2, 3 and 4, Jan-Feb., Mar-Apr., May-June and July-Aug., 1921, pp. 52–95, 358–386, 535–563, and 765–792, 38 figs. Author seeks to formulate the most important laws governing operation of trains on one-way divisions. Bibliography.

RAILWAY REPAIR SHOPS

Methods. Railway Machine Shop Practice. Machy. (N. Y.), vol. 27, no. 12, Aug. 1921, pp. 1098–1099, 5 figs. Methods of procedure in making common types of repairs that are required on passenger and freight cars.

Tools. Forge Shop and Other Railroad Shop Tools, Frank A. Stanley. Am. Mach., vol. 55, no. 9, Sept. 1, 1921, pp. 354–356, 11 figs. Tools and methods in use in western railroad shop. Special equipment to utilize air. Modern method of cleaning castings.

RAILWAY SHOPS

Lincoln, England. The Works of Clayton Wagons Limited, at Lincoln. Ry. Gaz., vol. 35, no. 6, August 5, 1921, pp. 251–255, 7 figs. Describes new works laid out for economical construction of railway rolling stock.

RAILWAY SIGNALING

Automatic. The Automatic Signaling Installation of the Berlin Electric Underground Railway and Certain Types of Pilots (Die selbsttätige Signalanlage der Berliner Hoch- und Untergrundbahn nebst einigen Vorläufern), G. Kemmann. Zeit. für Kleinbahnen, vol. 27, nos. 11 and 12, Nov. and Dec. 1920, pp. 392–402 and 438–457, 24 figs. partly on supp. plates. Nov.: Details of the separate parts of interlocking plant (Westinghouse system): illuminated signal boards; the d.c. relay; and the d.c. lamp signal box. Dec.: Safety installations in the Spittelmarkt station.

RAILWAY TRACK

Maintenance. Note on Mechanical Permanent Way Repairing Plant, M. Cartault. Engineering, vol. 112, no. 2903, Aug. 19, 1921, pp. 281–282. Describes use and mechanical equipment of the Collet system, in use since 1901 on Paris, Lyons & Mediterranean Ry. permanent way. Reprinted from Bul. Int. Ry. Assn.

Roadbed. On the Question of the Construction of the Road Bed and of the Track, Charles H. Ewing. Bul. International Ry. Assn., vol. 3, no. 7, July 1921, pp. 835–856, 11 figs. Discusses questions of ballasts, rails, tie plates, etc. and gives list of replies received from railway companies to a question blank

ENGINEERING INDEX (Continued)

RAILWAY YARDS

Illumination. Correct Illumination of Railway Freight Yards, J. H. Kurlander. Ry. Elec. Engr., vol. 12, no. 8, August 1921, pp. 299–306, 13 figs. Also in Ry. Age, vol. 71. no. 8, Aug. 20, 1921, pp. 337–340, 9 figs. Mounting height of lighting units is of prime importance in eliminating glare and obtaining best results. Bibliography.

REDUCTION GEARS

Heliocentric. The Heliocentric Reduction Gear. Machinery, (Lond.), vol. 18, no. 464, August 18, 1921, pp. 598–599, 3 figs. Describes new type of speed-reducing gear invented by W. C. Pitter and manufactured by Central Gear Co., Lond.

REFRACTORIES

Jointing Materials for. Notes on Jointing Materials for Refractories, L. Bradshaw and W. Emery. Gas Jl., vol. 155, no. 3036, July 20, 1921, pp. 157–159, 1 fig. Discusses jointing materials for refractories and influence of oxidizing and reducing atmospheres on refractory materials.

REFRIGERATING PLANTS

Electric-Motor Drive. Electric Motors for Driving Refrigeration Plants—Their Types, Characteristics, and Selection. W. H. Motz. Power, vol. 54, no. 6, Aug. 9, 1921, pp. 208–211, 5 figs. Discusses use of compound and synchronous motors.

Fish Refrigeration. New and Convenient Arrangement for Refrigerating Large Quantities of Fish (Un Dispositif Pratique et Nouveau Pour la Congélation de Grandes Masses de Poissons), Georges Delhoste. L'Outillage, vol. 219, no. 31, August 4, 1921, pp. 841–843, 7 figs. Describes unique installation, property of British Government.

REFRIGERATING MACHINES

Carbon-Dioxide. Refrigerating Machines (Machines Frigorifiques), A. Rullier. Arts et Métiers, vol. 74, no. 8, May 1921, pp. 150–153, 5 figs. Describes recent improvements in CO_2 machines.

ROLLING

Non-Metallic Products. The Rolling of Non-Metallic Products, Morris A. Hall. Raw Material, vol. 4, no. 8, August 1921, pp. 273–278, 9 figs. Discusses kinds of rolls in use in paper, textile and other non-metallic industries.

ROLLING MILLS

Homecourt, France. Completes French Rolling Mills. Iron Trade Rev., vol. 69, no. 8, Aug. 25, 1921, pp. 480–483, 5 figs. Pittsburgh company builds 44-in. reversing blooming mill, 48-in. universal plate mill and auxiliary machinery to be installed in plant at Homecourt. Description and layout of equipment.

Roll Making. How Steel Mill Rolls Are Made—II, H. E. Diller. Foundry, vol. 49, no. 16, August 15, 1921, pp. 631–638, 15 figs. Discusses metallurgy, melting and casting practice.

Making Rolls for Steel Mills, H. E. Diller. Iron Trade Rev., vol. 69, nos. 7 and 9, Aug. 18 and Sept. 1, 1921, pp. 419–424 and 432 and 547–554, 25 figs. Aug. 18: Different types of melting furnaces preferred for steel, chilled-iron hot, and chilled cold rolls. Sept. 1: Methods of molding steel and sand-cast rolls. How proper allowance for shrinkage is made in determining size and shape of chills.

Sheet Mills. Builds New Sheet Mill in East, E. C. Kreutzberg. Iron Trade Rev., vol. 69, no. 2, July 14, 1921, pp. 89–91, 5 figs. Plant in Baltimore designed for annual output of 70,000 tons of full finished stock. Labor-saving devices.

ROOFS

Tile. The Neupert Cantilever Tile Roof (Das Neupertsche freitragende Ziegeldach), H. Nitzsche. Beton u. Eisen, vol. 20, nos. 9–10 and 11, June 4 and July 4, 1921, pp. 108–111 and 127–128, 14 figs. Brief description of construction system with hollow brick, supporting capacity of which was confirmed by test load carried out by author in 1919. Static calculation of roof.

RUBBER

Technology. Rubber—From the Sap to the Finished Product, W. H. Holmes. Raw Material, vol. 4, no. 8, August 1921, pp. 281–289, 8 figs. Discusses principal rubber products: washing, drying and grinding machines; rubberized cloth; waterproofing, etc.

Vulcanization. Accelerators for Vulcanizing (Les Accélérateurs de la Vulcanisation), A. Neef. Révue Universelle des Mines, vol. 9, no. 1, S. 6, April 1, 1921, pp. 51–56. Discusses variety of organic accelerators in vulcanizing of rubber, their action, and future of process.

Vulcanized, Hardness of. The Modulus of Hardness of Vulcanized Rubber, H. P. Gurney. Jl. Ind. & Eng. Chem., vol. 13, no. 8, August 1921, pp. 707–712, 11 figs. Describes spring type and dead weight type of instruments for determining hardness.

S

SAFES

Reinforced-Concrete. The Thörig Reinforced-Concrete Safes Without Iron or Steel Casing (Kassenschränke aus bewehrtem Beton ohne Eisen- oder Stahlummantelungen nach "Bauweise Thörig"). Beton u. Eisen, vol. 20, no. 7–8, May 4, 1921, pp. 81–84, 14 figs. Describes patented system, according to which body of safe and door are made in iron forms as a monolithic whole, whereby outside and inside iron or steel linings are entirely eliminated and use of iron is otherwise reduced to a minimum. Use of reinforced concrete in place of iron is said to greatly increase safety against burglary.

SAND BLAST

Automobile Construction. The Use of Sand Blasts in the Construction of Automobiles and Engines (Die Verwendung von Sandstrahlgebläsen im Kraftwagen- und Motorenbau), W. Kaempfer. Motorwagen, vol. 24, no. 15, May 31, 1921, pp. 297–302, 13 figs. Enumerates purposes for which sand-blasting can be used in construction of automobiles and engines; and describes three different systems, the suction, gravity and pressure system.

SCIENTIFIC MANAGEMENT

See INDUSTRIAL MANAGEMENT.

SCRAP

Losses, Regulating. Regulating Losses from Scrap, Herbert R. Simonds. Iron Trade Rev., vol. 69, no. 3, July 21, 1921, pp. 157–161, 10 figs. Distinguishing between avoidable and unavoidable waste. Change in design often reduces scrap loss. Proper marketing.

SEAPLANES

Fairey Type III D. The Fairey Type IIID Seaplane. Flight, vol. 13, no. 33, August 18, 1921, pp. 552–557, 27 figs. Describes 360 hp. Rolls-Royce "Eagle" engine.

[See also FLYING BOATS.]

SEARCHLIGHTS

Anti-Aircraft. Tactical Organization and Employment of Anti-Aircraft Searchlights, John S. Pratt. Jl. U. S. Artillery, vol. 55, no. 2, August 1921, pp. 102–170, 24 figs. Discusses desirable characteristics, protection and concealment, night bombing flights, anti-aircraft defense, etc.

SEMI-DIESEL ENGINES

Operation. Semi-Diesel Engines (Les Moteurs Semi-Diesel). La Nature, no. 2463, June 18, 1921, pp. 395–398, 2 figs. Describes method of working generally and combustion chamber in particular.

SLAG

Blast-Furnace. Methods of Preparing Blast Furnace Slag. Iron Age, vol. 108, no. 8, Aug. 25, 1921, pp. 461–463, 4 figs. Divided into four classes by Carnegie Steel Co. according to specific use to which it is to be put.

SLOTTING

Machines for. Slotting Operations on Production Work. Machinery, (Lond.), vol. 18, no. 464, August 18, 1921, pp. 604–609, 12 figs. Discusses vertical planing, shaping, slotting and keyseating operations.

Slotting Operations on Production Work, Edward K. Hammond. Machy. (N. Y.), vol. 27, no. 12, Aug. 1921, pp. 1117–1122, 11 figs. Tooling up slotters and keyseaters for performance of vertical planing, shaping, slotting, and keyseating operations.

SPRINGS

Leaf. Formulas for Calculating Leaf Springs (Détermination de Formules Pratiques Pour le Calcul des Ressorts a Lames), H. Chaullet. Arts et Métiers, vol. 74, no. 8, May 1921, pp. 145–149, 7 figs. Works out formulas for various kinds.

STANDARDIZATION

German N. D. I. Report. Report of the German Industry Committee on Standards (Mitteilungen des Normenausschusses der Deutschen Industrie). Betrieb, vol. 3, no. 20, July 10, 1921, pp. 299–315, 23 figs. Proposals of Board of Directors for cotters; round threads; hexagonal and square-head bolts and nuts, carriage and countersunk bolts, lag screws, etc. Proposed standards for double anchor plates for T-head anchor bolts; wall anchor plates; T-head bolts; square nuts for anchor bolts, paper sizes, etc.

STANDARDS

Limit Dimensions. Determination of the Required Allowance Dimensions for Various Cylindrical Machine Parts (Feststellung der erforderlichen Passmasse für die verschiedenen Fabrikate), W. Kühn. Werkstattstechnik, vol. 15, no. 14, July 15, 1921, pp. 421–426, 7 figs. Notes on practical application of limit dimensions established by German Industry Committee on Standards (NDI).

STEAM

Dissociation. Steam Dissociation and Steam Jet Blowers in Theory and Practice (Wasserdampfzerfall und Dampfstrahlgebläse in Lehre und Anwendung), Hch. Doevenspeck. Zeit. für Dampfkessel u. Maschinenbetrieb, vol. 44, no. 14, Apr. 8, 1921, pp. 105–108, 2 figs. Points out that from practical standpoint the problem of turbo-blowers has not yet been solved, whereas the electric motor in boiler-room operation has proved to be both safe and economical.

Flow in Pipes. Convenient Tables for Steam Flow in Pipes, V. F. Davis. Power, vol. 54, no. 4, July 26, 1921, pp. 144–145. Table giving steam flow in pounds per minute for 100-ft. pipe and 1-lb. pressure drop; and factors to be applied to table for various lengths and pressure drops.

Specific Heat. Measurements of the Specific Heat of Steam and Its Technical Importance (Die bisherigen Messungen der spezifischen Wärme des Wasserdampfes und ihre technische Bedeutung), H. Schmolke. Zeit. für Dampfkessel u. Maschinenbetrieb, vol. 44, nos. 1 and 2, Jan. 7 and 14, 1921, pp. 3–4 and 12–13. History of development of investigations culminating in work of G. Eichelberg published in 1920.

STEAM ENGINES

Still Steam-Gas Type. The Still Engine (Der Still-Motor), H. Schuster. Zeit. für Dampfkessel u. Maschinenbetrieb, vol. 44, no. 16, Apr. 22, 1921, pp. 121–123, 3 figs. Discusses the Still combination internal-combustion and steam engine and prospects of its use for locomotive drive.

Uniflow. A Uniflow Engine Set at Slough. Elec. Times, vol. 60, no. 1556, August 11, 1921, pp. 123–124, 2 figs. Consists of Sulzer horizontal single-cylinder Uniflow direct-coupled to Oerlikon three-phase a.c. generator.

STEAM PIPING

Flange Blanks. Safety Flange Blanks (Sicherheitsflanschstücke). Der praktische Maschinen Konstrukteur, vol. 54, no. 23, June 9, 1921, p. 181, 3 figs. According to arrangement devised by Eisenberg & Schmöger, Dortmund, Germany, the cleaning or repairing of a battery can be effected without removing connecting pipe between boiler and collector, by adjusting between boiler and collector a pipe section as valve casing.

Reducing Costs of. Saving Effected Through Use of Valves with Low Resistance (Ersparnisse durch Verwendung von Absperrvorrichtungen mit geringem Einzelwiderstand), Karl Schmidt. Zeit, für Dampfkessel u. Maschinenbetrieb, vol. 44, no. 13, Apr. 1, 1921, pp. 97–101. It is shown how, under otherwise uniform conditions, installation and operating costs of pipe lines can be reduced when the separate resistance of the installed construction parts (especially the valves) are diminished.

STEAM TURBINES

Heating Steam from. Non-Condensing Turbine Operation on Heating Load, R. D. DeWolf. Power, vol. 54, no. 6, Aug. 9, 1921, pp. 220–221, 2 figs. Decentralized plants or units to recover electrical energy from heating steam. It is proposed to limit attendance for these machines to periodic inspection. Paper presented before Nat. Dist. Heating Assn.

STEEL

Alloy. See ALLOY STEELS.

Classification Code. Universal Steel Classification Code, Horace C. Knerr and Arthur L. Collins. Iron Age, vol. 108, no. 9, Sept. 1, 1921, pp. 515–517. Proposed new code to supplant present S.A.E. system. Claimed to be simpler, more elastic and easily expanded.

Drill. Manufacture of Drill Steel from Hollow Ingots. P. A. E. Armstrong. Iron Age, vol. 108, no. 10. Sept. 8, 1921, pp. 596–598, 2 figs. Process used by Ludlum Steel Co. and its advantages. Abstract of paper read before Am. Inst. Min. & Metallurgical, Engrs., with additional details and illustrations.

Endurance. Relations Between The Physical Properties of Steels and Their Endurance of Service Stresses, James E. Howard. Trans. Am. Soc. for Steel Treating, vol. 1, no. 11, August 1921, pp. 673–682. Discusses state in which steel best meets the conditions of service.

Ingots, Welding Defective. Welding Defective Steel Ingots, H. Brearley. Iron Trade Rev., vol. 69, no. 5, Aug. 4, 1921, pp. 289–292. Discusses blow-holes and segregate effect. Explains test method for determining extent of interior influences. Method of casting ingot is said to regulate imperfections. Paper read before Iron & Steel Inst.

Molybdenum. See MOLYBDENUM STEEL.

Silicon Additions. Silicon Additions to Steel. Iron Age, vol. 108, no. 8, Aug. 25, 1921, p. 458l. Effect of early and late introduction on gas content and rolling discard. Translated from article by Piwowarsky in Stahl u. Eisen, June 10, 1920.

Tool. See TOOL STEEL.

STEEL CASTINGS

Electric vs. Open-Hearth Furnaces. Compares Costs of Melting Steel. Iron Trade Rev., vol. 69, no. 3, July 21, 1921, pp. 167–170, 3 figs. Producer of steel castings operating both an electric and an open-hearth furnace gives data covering the two processes from which estimated costs are calculated.

STEEL FOUNDING

Converter Flame Examination. Spectroscopic Examination of Converter Flame, W. J. Campbell. Engineer, vol. 132, no. 3423, Aug. 5, 1921, pp. 137–138. Notes on the spectroscope and advantage of its use for many classes of small foundry work. Table giving outline of average blow and its spectroscopic examination.

STEEL, HEAT TREATMENT OF

Effect on Fatigue Strength. Effect of Heat Treatment on the Fatigue-Strength of Steel, E. P. Stenger and B. H. Stenger. Trans. Am. Soc. Steel Treating, vol. 1, no. 11, August 1921, pp. 617–635 and (discussion) pp. 635–638, 15 figs. Discusses effect of cold rolling and cold drawing, also effect of carbon content.

Temperature and Quality. The Carbonizing Process—Relation of Temperature to Quality of Cast and Core, Theodore G. Selleck. Trans. Am. Soc. Steel Treating, vol. 1, no. 11, August 1921, pp. 655–666, 9 figs. Gives a number of heat-treatment curves.

STEEL MANUFACTURE

American vs. English Practice. British View of American Steel Making, R. Percival Smith. Iron Age, vol. 108, no. 10, Sept. 8, 1921, pp. 589–591. Blast-furnace and open-hearth practice compared. Coke-oven gas as a fuel. Rolling mills in United States and England. (Abstract.) Paper read before West of Scotland Iron & Steel Inst.

ENGINEERING INDEX (Continued)

Making Steel, Arthur P. R. Wadlund. Trans. Am. Soc. for Steel Treating, vol. 1, no. 11, August 1921, pp. 682–689, 1 fig. Shows that the basic process is much more expensive than the acid process.

STEEL WORKS

Economic Location. Chicago's Relation to the Future American Steel Industry, Gerard de Geer. Chem. & Met. Eng., vol. 25, no. 8, August 24, 1921, pp. 325–328. Analysis of economic location of a steel industry in view of modern practice in coal economy, diminishing ore territory, increasing amount of scrap used, and greater influence of freight on finished product.

SUPERHEATERS

Performance. Steam Superheaters, Arthur D. Pratt. Jl. Engrs. Club of Phil., vol. 38, no. 200, August 1921, pp. 291–299 and Discussion pp. 299–308. Discusses construction and performances.

SWAGING

Cold. Methods Employed in Making Swaging Dies. Machinery (Lond.), vol. 18, no. 461, July 28, 1921, pp. 503–505, 8 figs. Subject of cold swaging.

T

TANKS

Collapse of Boston Molasses Tank. Eng. News-Rec. vol. 87, no. 9, Sept. 1, 1921, pp. 372–373. It is claimed that collapse was due to great overstress of tank shell.

TEMPERATURE CONTROL

Apparatus. The "Samson" Automatic Temperature Regulator. Engineering, vol. 112, no. 2904, Aug. 26, 1921, p. 307, 1 fig. Applied for operating, steam, gas, oil or water valves, or for controlling electric switches, and for regulation of room temperatures.

TESTING MACHINES

Alternating-Stress. The Haigh Alternating Stress Testing Machine. Engineer, vol. 132, no. 3422, July 29, 1921, pp. 116–117, 6 figs. Details of improved form.

TEXTILES

Microscopy of. The Microscopy of Textiles, Frederick J. Hoxie. Mech. Eng., vol. 43, no. 9, Sept. 1921, pp. 592–593, 3 figs. Notes on imbedding, sectioning and photographing. Points out that many irregularities in textile spinning, weaving and finishing, now a matter of mystery, can by photomicrographic records, be brought into realm of fact.

TIME STUDY

Drop-Forge Shop. Eliminating Unproductive Time in Industry. Eng. & Indus. Management vol. 6, no. 8, Aug. 25, 1921, pp. 205–207, 2 figs. Possible increase in production is emphasized by example of the drop-forge shop at Mare Island Navy Yard.

Human and Mechanical Elements of Work. Measuring the Human and Mechanical Elements in Manual Work, L. Arthur Sylvester. Indus. Management, vol. 62, no. 3, Sept. 1, 1921, pp. 141–144. Discusses natural relation between time and human labor.

Organization. How to Conduct a Time Study Organization, Chester D. Buoy. Indus. Management, vol. 62, no. 2, Aug. 1, 1921, pp. 104–105. Notes on purpose of time-study department, and qualifications for a time-study man.

Standard Time. "Standard Time" in Planning and Production, Waldo Lyon. Management Engrg. vol. 1, no. 2, Aug. 1921, pp. 105–108, 5 figs. How it is used to eliminate delays, estimate output and compare results of machine and department operation.

Wooden Knife Handles. Time Studies on Wooden Knife Handles, Philip Bernstein. Indus. Management, vol. 62, no. 2, Aug. 1, 1921, pp. 76–82, 11 figs. Author analyzes in detail operations on knife handles of various woods, data and conclusions being derived from actual experience.

TOOL STEEL

Specifications. Standardizing Specifications For Tool Steel, Charles M. Brown. Trans. Am. Soc. for Steel Treating, vol. 1, no. 11, August 1921, pp. 666–672. Discusses specifications in use, also content of tungsten, vanadium, phosphorus, sulphur, etc.

TRACTORS, FARM

Types. Mechanical Power in Agriculture (La Motoculture) F. Mirès. La Vie Technique & Industrielle, vol. 2, no. 23, Aug. 1921, pp. 401–409, 14 figs. Describes various types of tractors.

TRAIN HEATING

Electric Trains. Steam-Heating Electric Trains in Switzerland, William A. Rosenberger. Elec. Ry. Jl., vol. 58, no. 6, August 6, 1921, pp. 206–207, 2 figs. Single-phase current at 15,000 volts is applied directly to water in specially designed boiler.

TRANSPORTATION

Interdependence of Various Forms. Interdependence of the Various Forms of Transport, Philip Burtt. Jl. Inst. of Transport, vol. 2, no. 5, March 1921, pp. 233–247, 2 figs. Discusses ocean transport and railway traffic, light and heavy railways, inland waterways and other forms of transport.

TYPE-CASTING MACHINERY

Monotype. Building Type Casting Machinery. Eng. Production, vol. 3, nos. 46 and 47, Aug. 18 and 25, 1921, pp. 157–162 and 181–186, 27 figs. Methods in monotype factory of the Lanston Monotype Corp., Ltd.

V

VALVES

Gate, Electrically Operated. Electrical Operation of Gate Valves, Payne Dean. Fire & Water Eng., vol. 70, no. 8, Aug. 24, 1921, pp. 343–344, 4 figs. Value of quick electrical control through special devices. Description of control system.

Pump, Automatic. Investigation of Automatic Pump Valves and Their Effect on Performance of Pump (Untersuchung selbsttätiger Pumpenventile und deren Einwirkung auf den Pumpengang), Ludwig Krauss. Forschungsarbeiten auf dem Gebiete des Ingenieurwesens, no. 233, 1921, 112 pp., 172 figs. Deals will all conditions occurring in practice in different types of valves, based on experiments on six different kinds, carried out in machine laboratory of Dresden Technical Acad. Bibliography.

VENTILATION

Duct Systems. The Meier Chart, A. C. Pallot. Domestic Eng., vol. 41, no. 32, August 1921, pp. 115–120, 3 figs. Describes method of designing ventilation duct systems.

Nozzle or Air-Duct. Comparative Tests with a Nozzle and Air-Duct Ventilators (Vergleichende Versuche mit einer Düse und Luttenventilatoren), O. Leidenroth. Gluckauf, vol. 57, no. 17, Apr. 23, 1921, pp. 391–393, 2 figs. Results of experiments with a jet blower and air-duct ventilator demonstrate superiority of former. Advantages of the described Höing nozzle.

VISCOSIMETERS

Gümbel. Determination of Absolute Viscosity with the Gümbel Viscosimeter (Zur Bestimmung der absoluten Zähigkeit mit dem Gümbelschen Zähigkeitsmesser), Ludwig Schiller. Zeit. für technische Physik, vol. 2, no. 2, 1921, pp. 50–52. Deals with apparatus developed by Gümbel and described in same journal (vol. 1, 1920, p. 72), and method of calculating absolute viscosity from velocity of flow through apparatus. Comparison with the Engler viscosimeter.

W

WAGES

Incentive vs. Production Basis. Incentive or Production Basis of Wage Payment—III, Henry H. Farquhar. Am. Mach., vol. 55, no. 9, Sept. 1, 1921, pp. 344–348, 3 figs. Assignment and recording of production; coöperation with workman; fitting system to conditions; coöperation of executives.

Premium System. The Premium Wage Payment, System, C. B. Lord. Management Eng., vol. 1, no. 2, Aug. 1921, pp. 108–110. Principles and advantages of Halsey premium system.

Rate Determination. An Analytic Method for Determing Wage Rates, Edward Peterson. Management Eng., vol. 1, no. 3, Sept. 1921, pp. 146–148. Notes on determination of day-work and piecework rates.

WARFARE

Incendiary. Incendiaries in Modern Warfare, Part II, Arthur B. Ray. Jl. Indus. & Eng. Chem., vol. 13, no. 8, August 1921, pp. 714–722, 27 figs. Description of shells, bombs, flame projectors, etc.

WASTE ELIMINATION

Automatic Machinery, Use of. Eliminating Manufacturing Waste With Machinery, J. E. Hires. Chem. & Metallurgical Eng., vol. 25, no. 9, Aug. 31, 1921, pp. 410–412. Recognition of importance of engineering research and extensive use of automatic machinery as means of eliminating wastes in labor, time and materials.

Industrial. The Elimination of Construction Wastes, George W. Burpee. Chem. & Metallurgical Eng., vol. 25, no. 9, Aug. 31, 1921, pp. 394–396. Comprehensive dollars-and-cents analysis of preventable wastes in construction industries and thorough understanding of responsibility imposed upon contractor, owner, architect, engineer and workman.

Waste due to Poor Engineering and Management, Dexter S. Kimball. Chem. & Metallurgical Eng., vol. 25, no. 9, Aug. 31, 1921, pp. 375–377. Sound engineering practice and competent management are said to be most effective methods of eliminating waste. Accurate cost records of what has been done should make possible prediction of improved results.

Metal Trades Industry. Waste in the Metal Trades Industry, Fred J. Miller. Management Eng., vol. 1, no. 3, Sept. 1921, pp. 135–140, 4 figs. Abstract of field report on elimination of waste in industry based on studies in sixteen representative plants.

Research, Benefit of. The Role of Research in Waste Elimination, Harrison E. Howe. Chem. & Metallurgical Eng., vol. 25, no. 9, Aug. 31, 1921, pp. 379–382. Encouragement of fundamental research in America said to be more urgently needed than stimulation of industrial research. Fallacy of curtailing research and disrupting organization in times of Industrial depression. Examples of waste eliminated by research.

WASTES

Industrial. Waste and Inefficiency in the Industries. Chem. & Metallurgical Eng., vol. 25, no. 9, Aug. 31, 1921, pp. 433–448. Series of short articles by industrial leaders featuring outstanding causes of waste in various industries. Frank confessions of inefficiency due to wide variety of causes.

WATCH MANUFACTURE

Machines for. Automatic Machines in a Watch Factory, Fred R. Daniels. Machy. (N.Y.), vol. 27, no. 12, Aug. 1921, pp. 1093–1097, and vol. 28, no. 1, Sept. 1921, pp. 25–29, 14 figs. Machines, devices and methods employed in plant of Waltham Watch Co., Waltham, Mass.

WATER POWER

Canada. Canada's Fuel and Water Power Problems. Engineer, vol. 132, no. 3418, July 1, 1921, pp. 4–6, 4 figs. (Abstract.) Statements respecting relation of water power to Canada's fuel problems, published by Dominion Water Power Branch of Can. Dept. of Interior. Examples of waste eliminated by research.

Water Powers of the Prairie Provinces, C. H. Attwood. Jl. Eng. Inst. Can., vol. 4, no. 8, Aug. 1921, pp. 437–440. Resources, administration and market.

Geology and. Geology and the Hydroelectric Utilization of Water Falls (La Géologie et l'Aménagement Hydroélectrique des Chutes d'Eau), W. Kilian. La Houille Blanche, vol. 20, no. 53–54, May-June 1921, pp. 81–90, 9 figs. Discusses cement work along the rivers. (Concluded.)

WEIGHTS AND MEASURES

Accurate Equipment. The Essentials of Weighing in Industry, Herbert T. Wade. Management Eng., vol. 1, no. 3, Sept. 1921, pp. 129–134, 8 figs. Points out dependence of industry upon weighing, and advantages of good weighing practice and equipment. An example of routine weighing.

WELDING

Processes, Comparison of. The Present Status of Modern Welding Processes and Their Economy (Zum heutigen Stand der neueren Schweissverfahren und ihrer Wirtschaftlicheit), Paul Schimpke. Betrieb, vol. 3, no. 20, July 10, 1921, pp. 620–626, 11 figs. Review and comparison of different processes, their useful scope, efficiency and cost.

[See also ELECTRIC WELDING; ELECTRIC WELDING, ARC; ELECTRIC WELDING, RESISTANCE.]

WELFARE WORK

Coöperative Stores. Food as a Factor in Industrial Morale, John T. Bartlett. Indus. Management, vol. 62, no. 2, Aug. 1, 1921, pp. 83–88, 3 figs. It is claimed that the savings a coöperative store or farmers' market accomplish are equivalent to a wage increase.

Savings Plans. Thrift Encouragement by Employers—II and III, Leonhard Felix Fuld. Indus. Management, vol. 62, nos. 2 and 3, Aug. 1 and Sept. 1, 1921, pp. 93–94, and 139–140, Aug.: Discusses advantages of having employee authorize regular deductions from his pay, these deductions to be put into his savings account. Sept.: Bonus systems; savings and loan associations; the employer's position.

WIRE DRAWING

Dies for. Wire Drawing Dies With Connected Guides (Filières d'Étirage a Touches Rapportées), A. Catherine. L'Outillage, vol. 219, nos. 29 and 31, July 21 and Aug. 4, 1921, pp. 795–797, 12 figs., and 839–840, 8 figs. Describes improved methods of wire drawing and construction of guides.

Nail-Making Factory. Wire Drawing and Nail Manufacture. Eng. Production, vol. 3, no. 47, Aug. 25, 1921, pp. 175–177, 7 figs. Plan and methods of a Belgian Factory.

WIRE ROPE

Care of. Instruction in the Care, Uses, and Inspection of Flexible Steel Ropes, H. C. Boynton and W. Voigtlander. Jl. Engrs'. Club of Phila., vol. 38–7, no. 199, July 1921, pp. 274–279. Discusses production and treatment of steel, manufacture of wire rope lubrication and inspection.

WOMEN WORKERS

New Avenues of Employment. The New Place of Women in Industry—VI, Ida M. Tarbell. Indus. Management, vol. 62, no. 2, Aug. 1, 1921, pp. 106–108. Discusses new professions which have opened for women as outgrowth of expanding interest in personnel work.

WOOD

Drying. The Artificial Drying of Timber (Die künstliche Trocknung von Nutzhölzern), Otto Brandt. Der praktische Maschinen-Konstrukteur, vol. 54, no. 24, June 16, 1921, pp. 185–200, 23 figs. Notes on composition of wood and nature of wood drying; steaming; construction and equipment of dry kilns with forced hot-air circulation; plants for drying lumber loaded on cars; heat and air requirements for wood-drying plants; stacking of timber; artificial drying methods with electricity, by chemical means, and through cooling with aid of refrigerating plant.

WOOD PRESERVATION

Mine Timbers. Comparative Tests with Preservation Processes for Mine Timbers (Vergleichsversuche mit Imprägnierungsverfahren für Grubenholz), O. Dobbelstein. Glückauf, vol. 57, no. 26, June 25, 1921, pp. 601–607, 18 figs. Final report of special testing committee on investigation of wood impregnated in 1913 and 1914 and installed in two mines, which was examined annually for the five succeeding years.

WOODWORKING INDUSTRIES

Yield Values. "Yield Value" Variations in Woodworking, W. L. Churchill. Management Eng., vol. 1, no. 1, July 1921, pp. 17–21, 6 figs. How they affect profits due to sliding scale of lumber values.

Mechanical Engineering

The Monthly Journal Published by

The American Society of Mechanical Engineers

Publication Office, 207 Church Street, Easton, Pa. Editorial and Advertising Departments at the Headquarters of the Society, 29 West Thirty-ninth Street, New York

Volume 43 December, 1921 Number 12

TABLE OF CONTENTS

Price 50 Cents a Copy, $4.00 a Year: to Members and Affiliates, 40 Cents a Copy, $3.00 a Year. Postage to Canada, 50 Cents Additional; to Foreign Countries, $1.00 Additional. Changes of address should be sent to the Society Headquarters.

Entered as second-class matter at the Post Office at Easton, Pa., under the Act of March 3, 1879.
Acceptance for mailing at special rate of postage provided for in section 1103, Act of October 3, 1917, authorized on January 17, 1921.

Contributors and Contributions

Boiler and Furnace Economy

D. S. Jacobus

Dr. David S. Jacobus, who writes on Boiler and Furnace Economy in this issue, at the present time acts as advisory engineer for The Babcock and Wilcox Company. Graduating from Stevens Institute in 1884 he was appointed assistant professor of experimental mechanics. The full professorship of experimental mechanics and engineering physics was conferred upon him in 1897 and he served in this capacity until 1906, when his relationship with The Babcock and Wilcox Company began. He received the honorary degree of Doctor of Engineering from Stevens Institute in 1906. Dr. Jacobus has written many scientific papers on engineering subjects and has been exceedingly active in engineering societies, especially in The American Society of Mechanical Engineers, which he served as president in 1915–16 and previously as manager and vice-president.

Heat Balance in Steam Power Plants

Four papers giving valuable data on steam power plant heat balance are published in this issue of Mechanical Engineering.

Ernest L. Hopping, who writes of the Delaware Station, is engineer of station mechanical design and construction for the Philadelphia Electric Company, having served with the company since 1911. His previous experience was gained mainly with various machine and engine constructors in Philadelphia where he worked on the design of locomotive parts, electric cranes, and stationary engines.

Charles W. E. Clarke, of the Dwight P. Robinson Company, presents data from Colfax Station. Mr. Clark received his early experience in Chicago. He designed several power and refrigerating plants for Armour and Company, and as chief draftsman for Sargent and Lundy was in charge of design, specification and construction work for installations aggregating 100,000 kw. in and near Chicago. From 1907 to 1910 he was in charge of mechanical engineering in the New York electrical zone for the New York Central Lines, and thereafter was associated with Stone and Webster in charge of a large number of power developments. Since 1919 Mr. Clarke has been associated with the Dwight P. Robinson Company.

John H. Lawrence, one of the co-authors of the Hell Gate Station paper, is a 1909 Cornell graduate and was in the service of the New York Edison Company in design and installation capacities until 1918. Since late in 1918 he has been in the employ of the Thomas E. Murray Co., at present holding the position of engineering manager.

Walter H. Keenan, Mr. Lawrence's collaborator, was graduated from Cornell in 1911 and was employed in laboratory research and design work by the New York Edison Company until 1919. He is a present assistant engineering manager for Thomas E. Murray Co.

Wastes in Handling Material

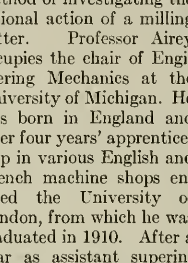
Harold V. Coes, who presents a timely paper on the principles involved in handling material economically, is manager for Ford, Bacon and Davis at Philadelphia. Mr. Coes, a graduate of Massachusetts Institute of Technology in 1906, has had broad experience in design and operation. He has been with Ford, Bacon and Davis since 1917.

On the Art of Milling

John Airey

Prof. John Airey and Carl J. Oxford present an exceedingly interesting method of investigating the rational action of a milling cutter. Professor Airey occupies the chair of Engineering Mechanics at the University of Michigan. He was born in England and after four years' apprenticeship in various English and French machine shops entered the University of London, from which he was graduated in 1910. After a year as assistant superintendent of a Swiss machine shop he came to America as instructor in engineering mechanics at Michigan, later acting as assistant professor and receiving the full professorship in 1919. During the war for nine months Professor Airey served as assistant inspector of munitions for the British Government and for two years was in charge of the engineering and mechanical department for the R. and V. Wagner Ordnance Company. He has made many contributions to the technical press.

Mr. Oxford was born in Norway and came to the United States in 1909. After two years in the engineering department at the University of Michigan, he served as tool draftsman with the Packard Motor Car Company, Dodge Brothers, and Nordyke and Marmon until 1916, when he became designing engineer for the Wilt Twist Drill Company. He entered the service of the National Twist Drill and Tool Company of Detroit in 1917 and is now chief engineer.



Carl J. Oxford

Wastes in the Machine Shop

James A. Smith, who contributes a paper on Salvaging Industrial Wastes, printed in this issue and to be presented at the Machine Shop Session of the A.S.M.E. Annual Meeting, is general superintendent of the Schenectady Works of the General Electric Company, with which concern he has been associated since January 1910. Previous to that he had eleven years' experience with the Pratt and Whitney Company and six years' service as superintendent of the Dutchess Tool Works at Fishkill-on-the Hudson.

MECHANICAL ENGINEERING

Boiler and Furnace Economy

By D. S. JACOBUS,[1] NEW YORK, N. Y.

That it is possible to effect material savings in power plants is evident, according to the author, when it is considered that fifty or even a hundred per cent more fuel is burned in some cases than would be required by plants of the best economy. It does not follow, however, that it would pay to replace all plants of low efficiency by those having a higher efficiency. There are many factors which must be taken into consideration before deciding that a new investment is warranted, and each case must be considered individually in order to determine whether or not it will pay to replace an existing plant by one of more economical type, or to add apparatus to increase the efficiency.

The present paper accordingly deals with such questions as when it will pay to use economizers in a new plant; the most economical rating at which to operate a boiler; limitations imposed on efficiency by inability of furnace brickwork to withstand temperatures available with many classes of fuel; furnace volume and length of flame travel; where air heaters are of especial advantage; importance of employing properly trained men for boiler operation: information afforded by flue-gas analysis, etc., etc.

The author points out in closing that furnace and boiler design must be coordinated in order to secure the best results. It is impossible to separate the boiler efficiency from the efficiency of the stoker and furnace in such a way that the value obtained for the former will depend solely on the construction of the boiler and not be influenced through the construction of the stoker and furnace The stoker and furnace efficiency is influenced by the delayed or secondary combustion between the boiler tubes and this cannot be included in any analysis, neither can the loss due to excess air be correctly divided between the boiler and furnace.

THERE has been a steady improvement in the economy of power plants, on account of the increase in fuel costs and to keep pace with the advance in the art. Particular attention is now being given to savings in view of the economic struggle which appears to be before us. That material savings can be effected in power plants is plain when it is considered that 50 or even 100 per cent more fuel is burned in some cases than would be required by plants of the best economy. It does not follow, however, that it would pay to replace all plants of low efficiency by those having a higher efficiency. There are many factors which must be taken into account before deciding that a new investment is warranted and each case must be considered by itself in order to determine whether or not it will pay to replace an existing plant by one of more economical type, or to add apparatus to increase the efficiency. Adding an economizer will ordinarily add to the thermal efficiency; the same applies to an air heater, but in considering all features it may be found that the character of the load, the class of operation, and the fuel conditions are such that it will not pay to install an economizer or an air heater.

When It Will Pay to Use Economizers in a New Plant

In determining whether it will pay to use economizers in a new plant the problem should not be approached by comparing the efficiency of a boiler with that of the same boiler with an economizer added to it. The proper way is to compare the results to be expected from boilers best suited for the service without the addition of economizers, with the results to be expected from the best combination of boilers and economizers. It will sometimes be found for certain load conditions that a larger boiler properly designed and baffled will give better commercial returns, all features considered, than a smaller boiler with an economizer, or for that matter, than any boiler that can be selected with an economizer. In the case of an old plant, the question of whether or not it will pay to add economizers to the boiler is a simpler one to answer than for a new plant, as the added efficiency due to the economizers may be readily computed on the basis of the known flue-gas temperatures, gas weights, etc., but here again the load conditions must be taken into account, as well as the fact that there will be an increased cost of upkeep and added complication through the necessity of installing an induced-draft apparatus. For peak-load service where the peaks are of short duration, say an hour or so a day, it does not in most cases pay to install economizers on all of the boilers. A good arrangement may be secured for some classes of service by adding economizers to some of the boilers and operating them at a more nearly uniform load than the rest of the boilers, the boilers that have no economizers being held in reserve and cut in during the peak-load periods. Another case where it does not pay to apply economizers is where boilers are used for stand-by service. Where the operation is more or less continuous it pays in most cases to use economizers. The cost of fuel is a governing factor. The increase in fuel costs during the last few years has caused economizers to be used more generally than formerly and we are approaching more closely to European practice in the number of boilers fitted with economizers.

Increasing the Efficiency by Adding to Height of Boiler

In designing a boiler for use without an economizer additional efficiency may be secured by adding to the height of the boiler. Adding to the height of the boiler so as to increase it from, say, 14 tubes high to 20 tubes high, will result in a considerable increase in efficiency with but little increase in the draft loss. In many instances the higher boilers may be operated with natural draft at the desired capacity, thereby eliminating the added complication of the induced-draft apparatus that would be required for economizers. Of course, it would be impossible to operate a high boiler of the sort with natural draft at as high a percentage of rating as a lower boiler, as the flue-gas temperature at a given rating would be considerably lower than with the lower boiler, and this would reduce the amount of draft available from the stack.

Wrought-steel economizers are coming into use to a greater extent than formerly. We have learned how to prevent interior corrosion in a wrought-steel economizer by reducing the oxygen content of the feedwater with as low a temperature of feedwater as can be enployed in a cast-iron economizer. To avoid exterior corrosion through the condensation of moisture from the flue gases, the temperature of the feedwater to the economizer must be kept above a temperature of about 120 deg. fahr., and for most work 140 deg. fahr. is preferable, as this allows for some leeway in case the water is fed intermittently. There is more difficulty through exterior corrosion in intermittent service than where the service is more or less continuous, as soot which collects on the outside of the economizer is apt to become moist during the time that the economizers are down or are being started up, and the presence of moisture makes the soot from certain fuels highly corrosive. Coals having a high sulphur content give the most trouble through exterior corrosion, and with such coals the temperature at which the water is fed to the economizers should be somewhat higher than for coals having but little sulphur.

An Individual Economizer for Each Boiler

It is becoming more general practice to use an individual economizer for each boiler and not to install connections for by-pass-

depositing moisture and acid on the colder portions, and all of these features should be considered before deciding to use an air heater.

Importance of Employing Well-Trained Men for Operation of Boilers

Irrespective of how well a boiler plant may be designed, it will not give the best results unless it is properly operated. The man in charge of the boiler room is the "man behind the gun" when it comes to securing the best obtainable efficiency. The old idea that a man should graduate from the boiler room to the engine room is a mistake, as a good man in the boiler room can increase the efficiency through good operation far more than one in the engine room. Happily more attention is now being paid to this feature, with correspondingly good results.

All of those who have had much to do with increasing the efficiency of power plants know that often the simplest requirements of good practice are disregarded in the operation of boilers, the boilers often being dirty and run with leaky baffles and settings. Even where the boilers and settings are kept in good condition there may be a loss through improper firing. The fireman is often blamed as a factor of fuel waste. The difficulty is seldom with the fireman, but in having nothing to guide the fireman except what might be called his intuition. It is certainly a mistake not to provide proper instruments. This is well appreciated in the larger and best-run power plants, but there is often a lack of instruments that makes it impossible to operate the plant to the best advantage. There is no reason why operating results should not be as good as test results, and this can only be accomplished through installing high-grade indicating and recording apparatus for the guidance of the fireman and operators. The plants of today are of a more complex character than in the past and the success in operating these plants depends in a great measure on the use of the proper instruments and a proper training of the man.

Information Afforded by Flue-Gas Analyses

In the operation of a plant much is shown by the flue-gas analyses. The flue-gas analyses are not all that govern the efficiency, as much depends on whether or not there is delayed combustion between the tubes of the boiler. It is all wrong to assume that if two boilers are operated with the same average flue-gas analysis and percentage of carbon in the ash that the furnace efficiency is the same in each, as actually there may be a wide difference due to the fact that all of the combustible gases may be consumed in the furnace in one case and not in the other.

A small amount of CO is often present when a high percentage of CO_2 is carried. An analysis with coal firing which indicates 13 per cent of CO_2 and no CO is about equivalent from a heat-loss standpoint, where the flue gases leave boiler and economizer at 500 deg. fahr., to one which gives 15 per cent CO_2 and $^1/_4$ per cent of CO. Again, carrying a high percentage of CO_2 sometimes leads to secondary or delayed combustion between the boiler tubes, thereby involving an additional loss through increasing the temperature of the flue gases. It is important, therefore, in boiler-room practice to make accurate analyses to determine whether or not CO is present in the flue gases and also to avoid too great an amount of delayed combustion between the boiler tubes.

Automatic systems for combustion control are often used to advantage. The supply of fuel is regulated in some cases to meet the demand for steam as well as the amount of air supplied for combustion. Systems where the amount of fuel is automatically regulated are in more general use in oil burning than for coal. In most cases the air supply is regulated to correspond to the fuel burned and to give a proper amount of draft within the furnace, and the fuel supply is hand-adjusted. Such systems quickly regulate the air and draft, and in some cases the fuel as well, to meet changing load conditions, and are especially useful where there is a variable load.

High-class instruments and apparatus for guiding the firemen or controlling the combustion will not of themselves insure good results. Many such devices that would give highly satisfactory results in the hands of a capable man that believes in them would be a failure in the hands of one less capable or one prejudiced against them. Here again all depends on the man in charge, and as the art advances and more complicated apparatus is used in obtaining higher efficiencies, more competent men are required.

Necessity of Coordinating Boiler and Furnace Design to Secure Best Results

Furnace and boiler design must be coördinated in order to secure the best results. It is impossible to separate the boiler efficiency from the efficiency of the stoker and furnace in such a way that the value obtained for the efficiency of the boiler will depend solely on the construction of the boiler and not be influenced through the construction of the stoker and furnace. Many have worked on this problem and the ground has probably been gone over more thoroughly than any other feature in boiler-testing codes. The stoker and furnace efficiency is influenced by the delayed secondary combustion between the boiler tubes and this element can not be included in any analysis, neither can the loss due to excess air be correctly divided between the boiler and furnace. The element of delayed combustion may influence the overall boiler and furnace efficiency, say, 5 or 10 per cent with the same flue-gas analyses. In most proposed methods the stoker and furnace efficiency is based on the analyses of the flue gases and on the amount of unconsumed carbon in the ash, and it can be readily seen that such a basis cannot give reliable results. Should it be possible to accurately express the furnace and stoker efficiency, a purchaser should obtain the same overall economy from his boilers with any arrangement of stokers and furnaces having a given efficiency. There is no method, however, whereby this result could be insured and whereby the purchaser would be protected should he assume that the boiler and furnace efficiency would be an exact measure of the relative advantages of using one or another of the various stokers and furnaces in connection with his boilers.

Stainless steel is an alloy steel containing about 12 to 14 per cent of chromium. It may be hardened in air, oil, or water, and tempered to various degrees of hardness as required for the different purposes for which it is intended. Ordinary carbon tool steel is hardened from a temperature of 760 to 780 deg. cent. for the maximum hardness to be obtained; with stainless steel, however, the temperature for effective hardening is higher, and it is recommended that temperatures between 950 and 1000 deg. cent. be used. This is due to the fact that the phase changes take place at a much higher temperature than in ordinary carbon steels. The difference in hardening temperature can be illustrated by stating that ordinary tool steel may be hardened from a red heat, while stainless steel should be taken to an orange-yellow heat.

Stainless steel may be supplied either in, or to be put in, the hard condition as for cutlery; in the machinable condition as for pump rods, turbine blades, etc., and in the malleable state required for presswork, etc.

Hence it is desirable that engineers should definitely state the purpose for which they desire to employ the material. For the manufacture of cutlery it is supplied in the annealed condition, since the final processes of manufacture include the hardening of the blades. For use in the machined condition it is available in the specially heat-treated condition, complying with the mechanical properties required for specific engineering purposes, thus obviating any necessity for further treatment by the user. For presswork it is produced within such limits of composition and treatment as to insure a satisfactory malleable stainless steel as required for articles as are manufactured from sheet steel, etc.

The most common of corrosive influences—i.e., weathering agents—have little effect on stainless steel. Samples have been exposed to the weather, wet and dry, frost and snow, for many months, and at the end of the time have been perfectly bright and unaffected in any way. Samples have been placed in streams, and after twelve months have still maintained their pristine brightness. Nitric acid, oleic acid, stearic acid, benzol, and petrol are without effect; phosphoric acid in concentrated form has no effect, but 75 per cent solutions give a slight general attack. Citric acid and formic acid cause corrosion to some extent, but for the great majority of liquids tested the steel was unaffected.—*Mechanical World*, Oct. 28, 1921.

This paper gives particulars of an investigation undertaken at the University of Michigan for the purpose of finding a rational basis for the action of a milling cutter.

It is shown that metal is removed more efficiently with thick chips than with thin chips. It follows from this that, other conditions being equal, including speed and feed per minute, the cutter with the fewest teeth gives the greatest efficiency. However, it is evident that the efficiencies of two cutters with different numbers of teeth are equal provided the table feeds be adjusted so that the same feed per tooth is effected. This gives a definite working theory on the influence of spacing.

It is definitely established that for a given material, tooth shape and sharpness, thickness of chip is the sole criterion of the efficiency with which metal is removed in milling and that increase of spacing over that required for free cutting is a handicap. Present-day high-powered cutters have several times the chip space needed. Limitation of machine power has doubtlessly been the chief factor in giving a false bias to the influence of spacing.

Formulas for determining the number of teeth for a known diameter of cutter and for determining the depth are included in the paper, as well as a geometrical construction for obtaining the best shape of tooth.

THE practice of milling has, during the present century and the last decade of the nineteenth century, encroached decidedly on the field occupied by the shaper and planer. The action of milling possesses advantages over shaping; it also has its drawbacks. Much work must be done before we can state the relative merits or potentialities.

In the art of milling, the only published investigations have been handled by machine-tool builders. Attention has in consequence been focused more on the machine than on the cutter. Further, in the investigations already made, the objects sought have usually had the defect of being too immediate. This paper describes an

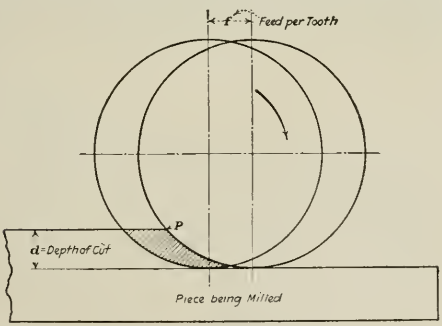

Fig. 1 Shape of Milling Chip

attempt to investigate the fundamental principles underlying the action of milling.

It is shown in the present investigation that metal is removed more efficiently with thick chips than with thin chips. It follows from this that, other conditions being equal, including speed and feed per minute, the cutter with the fewest teeth gives the greatest efficiency. However, it is evident that the efficiencies of two cutters with different numbers of teeth are equal provided the table feeds be adjusted so that the same feed per tooth is effected. This gives a definite working theory on the influence of spacing.

In addition to the present investigation, experiments published in substantiation of the advantage of wide spacing agree in confirming this theory. It is definitely established that for a given material, tooth shape and sharpness, thickness of chip is the sole criterion of the efficiency with which metal is removed in milling and that increase of spacing over that required for free cutting is a handicap. Present-day high-powered cutters have several times the chip space needed. Limitation of machine power has doubtlessly been the chief factor in giving a false bias to the influence of spacing.

The work described in this paper started in May, 1920, through a desire of the National Twist Drill and Tool Company of Detroit to find a rational basis for the action of a milling cutter, so far as this could be removed from the region of empiricism. This com-

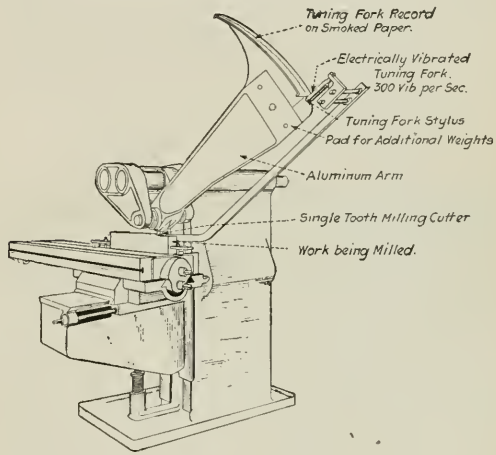

Fig. 2 Chip Investigator

pany furnished the financial support throughout. The experiments have been conducted in the Engineering Shops of the University of Michigan, and at the works of the National Twist Drill and Tool Company, the Lincoln Motor Company and the Hudson Motor Car Company. The greater part of the work was done at the University of Michigan, but the tests on machineability were run at the works of the National Twist Drill and Tool Company and those on endurance at the two automobile plants.

A Dynamical Study of Single-Tooth Action

The chip taken by a plain slab mill is very different from the chip taken by a lathe or shaper tool. A milling chip is shown exaggerated in the shaded portion of Fig. 1. The two circles show the outline of the cutter at the beginning and at the end of the interval taken for the cutter to revolve through the angle subtended by one tooth. The shaded portion will therefore represent the material removed by one tooth and will have an area $f \times d$.

The chip starts infinitely thin and its thickness gradually increases to a maximum just before the finish, from which point it quickly decreases. This decrease is practically instantaneous in an unexaggerated chip. The question arises, how does the force vary throughout the cutting of this chip?

The first problem is to find how the tangential force varies in relation to chip thickness. For measuring this force while the chip is being formed under reasonable commercial velocity conditions, a dynamical measuring method is the only solution, as a chip is completely cut in about one-tenth of a second.

Description of Chip Investigator. Fig. 2 is a diagrammatic representation of the apparatus here known as the Chip Investigator. A block of material is shown bolted to a milling-machine table

[1] Professor of Engineering Mechanics, University of Michigan. Mem. Am.Soc.M.E.

[2] Chief Engineer, National Twist Drill and Tool Co. Assoc-Mem. Am. Soc.M.E.

For presentation at the Annual Meeting, New York, Dec. 5 to 9, 1921, of The American Society of Mechanical Engineers. The paper is here printed in abstract form. All papers are subject to revision.

and a single-tooth cutter in place, the latter being rigidly attached to the sector-shaped arm. This arm can partially rotate about an axis at its lower end, and in so doing it carries the cutter through an arc long enough to make a chip of the desired length.

If the arm be allowed to fall freely, the angular velocity will increase throughout the fall. If this be repeated after the table is adjusted so as to cause a cut to be taken, then the next fall of the arm will be retarded, because it must give up sufficient energy

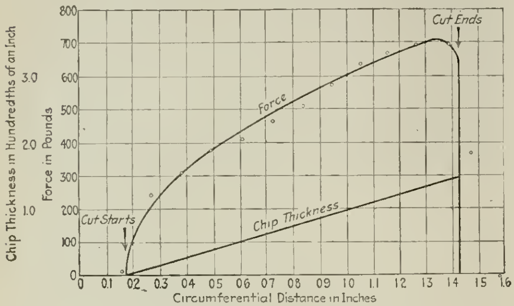

Fig. 3 Force-Space Curve of Chip Formation

to do the cutting. Weights can be placed on the Pad for Additional Weights (see Fig. 2) sufficient to secure a roughly uniform speed during cutting.

The investigation of the velocity at each instant is made by means of a tuning fork, which gives a record on smoked paper. The outer surface of the arm, remote from the axis of oscillation, is concentric: to this a glazed paper ribbon is attached and then smoked by a gas flame.

An angle iron bolted to the front face of the machine carries at its upper end a Koenig electrically driven tuning fork making 500 vibrations per second. As the arm falls, a wavy line is traced on the smoked paper by a stylus attached to one leg of the tuning fork. Each wave represents a definite interval of time, viz., two one-thousandths of a second. The smoked-paper record is immediately dipped in thin shellac varnish and hung up to dry.

An example of a chip study is given in Fig. 3, where it is very clearly shown that the force employed is not proportional to the chip thickness. In other words, material is removed more efficiently as the chip becomes thicker. This is confirmed later by experiments on varying feeds and furnishes the true explanation of the supposed advantages of coarse-tooth cutters.

Over twelve hundred chips were cut and the energy computed. These were taken at three different cutting speeds, viz., 17.5, 32 and 44 ft. per min., respectively. The average of the energy required at different speeds was remarkably equal. If the energy used at lowest speed be taken at 100, the results are:

Speed in ft. per min......	17.5	32	44
Energy..................	100	101.8	97.4

As there appears to be no law in this and the variation is slight, presumably due to experimental error, the conclusion was reached that speed does not influence energy required.

Influence of Rake and Feed on Cast Iron. The results of the analysis of sixteen sets of chip formations in cast iron are given in Figs. 4 and 5. Each set consists of three chips formed at the different speeds as stated in a previous paragraph.

The area under each curve gives a numerical representation of the average production of each tool over a certain region of chip weight. Taking the 0-deg. rake tool as 100, we have:

Production of 0-deg. rake tool = 100
Production of 10-deg. rake tool = 133
Production of 20-deg. rake tool = 138.4
Production of 30-deg. rake tool = 142.1

Influence of Rake and Feed on Bronze, Machine Steel and Carbon Tool Steel. The results of the analysis of sixteen sets of chip formations each in bronze, machine steel and carbon tool steel are given in the following table. As in the case of cast iron, the consistent superior economy of heavy feed is observed. This information is condensed as before and results in:

	Bronze	Machine Steel	Carbon Tool Steel
Production of 0-deg. rake tool	= 100	100	100
Production of 10-deg. rake tool	= 113.2	118.7	106
Production of 20-deg. rake tool	= 123	157.2	112.2
Production of 30-deg. rake tool	= 118	172	112

Effect of Lubrication. Various experiments were run with lubricants. The results must be taken qualitatively rather than quantitatively. This topic offers an important field of investigation for future experiments.

In milling there is a decided influence entirely apart from heat-conducting properties. If the surface exposed by the last chip was very slightly smeared with an oiled finger (the oil film was

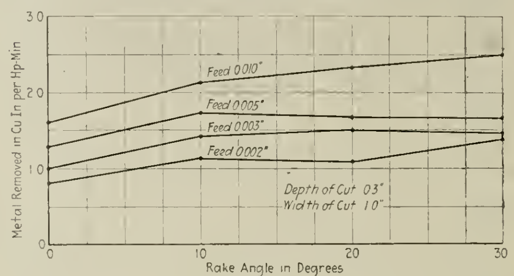

Fig. 4 Milling Tests on Cast Iron: Metal Removed as a Function of the Rake

scarcely discernible), the energy consumed in taking the next chip was from 10 to 25 per cent lower in nearly all cases.

On plotting batches of results, however, the surprising situation was found of oil proving advantageous with low rakes in bronze and detrimental with high rakes. The existence of some unknown varying factor was suspected and the results would have been

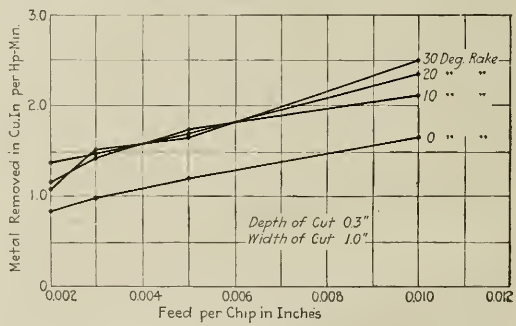

Fig. 5 Milling Tests on Cast Iron: Metal Removed as a Function of the Feed

rejected and forgotten but for the fact that the same effect showed up in experiments with machine steel made at a different time. The metal removed per horsepower-minute is shown plotted against rake for the two materials in Fig 6.

The authors hesitate to accept the foregoing unreservedly until further investigation sheds some light on its rationality. A study of the resultant force during the formation of a chip with reference to its changing magnitude and direction would give the needed explanation. This has not yet been undertaken.

Effect of Chatter. When chatter occurs, a violent fluctuation of energy results. The energy consumed was usually greater than with smooth cutting. The authors believe that, due to chatter alone, increase of energy invariably results and that where a decrease appeared it was caused by the cut being lighter than supposed to be. This can be brought about by the chatter causing

the work or cutter. A detailed study of chatter was not made, but probably will be at a later date.

Effect of Clearance. Clearance was found not to affect energy consumed. Chatter, wear of tool and liability of tool to snip are affected by clearance.

Effect of Spiral. Experiments were carried out on the effect of spirals. The results were not sufficiently uniform to justify a conclusion on the influence of spiral angle on energy, beyond the fact that cutters with spiral angles of over 25 deg. certainly require more energy.

Method of Determining Machineability. The word "machineability" is suggested to indicate the ease with which a given material can be machined. This, of course, presupposes standardized conditions of tool and size and shape of chip. If all conditions be

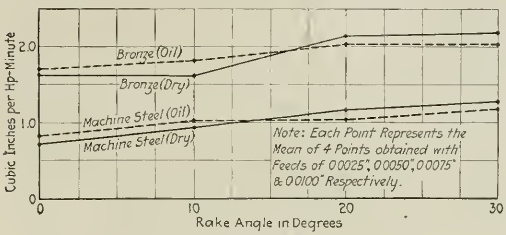

Fig. 6 Effect of Oil on Milling Machine Steel and Bronze

standardized except the quality of the material being cut, then the machineability can be expressed in foot-pounds of energy required to remove one cubic inch of the material under investigation.

It is well known that machineability is a continual bone of contention in machining departments and that no accepted satisfactory way has yet been devised for its measurement. It is generally admitted that even though chemical analysis, tensile strength, elongation, Brinell hardness number and scleroscope hardness number are known, yet the machineability is an unknown factor. In fact, the War Department gave to the American

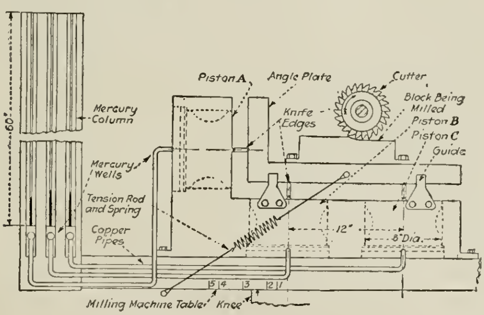

Fig. 7 Thrust and Torque Measurer

Research Council as their major topic the development of some definite means of determining machineability.

A machine has been developed along these lines and is described later in the paper. For identification purposes it is referred to as the "Machineability Tester." Experiments with this machine are presented at the end of the paper rather than here, because they were the last experiments to be performed.

To summarize: The authors had, at this stage of development, no definite idea leading to a rational structure which would connect up the results. They regard the work already described as useful in opening up territory, thereby enabling them to formulate more definite layouts for subsequent work and believe that broadly the following conclusions are justified:

1 As a chip thickens, metal is removed more easily per unit volume

2 ... per unit volume. Also this improvement is continuous but not uniform

3 The advantage of rake depends on the material and is more pronounced with ductile materials

4 The effect of lubrication proper (apart from cooling action) is decided, but the information available is inadequate to formulate it.

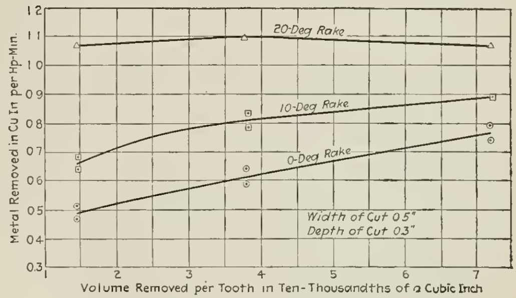

Fig. 8 Influence of Rake in Cutting Machine Steel

Force Analysis of Cutter in Action

It was thought desirable to measure both the vertical and horizontal components of the force exerted by the cutter. This necessitated developing an instrument that would measure both force and location, i.e., in all, three quantities: magnitude, direction and location. Or, which amounts to the same thing, the two components and the location may be measured.

Description of Equipment Employed. The apparatus developed for force and power analysis is shown diagrammatically in Fig. 7, and is designated the "Thrust and Torque Measurer."

The angle plate to which is bolted the material being cut is carried on three knife edges, through which the forces are transmitted to pistons *A*, *B* and *C*. The double-knife-edge principle used transmits only a horizontal force to piston *A* and only vertical forces to pistons *B* and *C*.

The fluid pressure under the pistons is transmitted through pipes and measured by means of mercury columns shown at the left of Fig. 7. As the table travels in feeding, the location of the downward thrust of the cutter in relation to cylinders *B* and *C* changes continuously. The table traveling from left to right results in the pressure decreasing on *C* and increasing on *B*. The readings of mercury columns must therefore be taken for known definite locations of table. Five marks were made in the table, and as these successively came into alignment with a zero mark on the saddle, the readings were taken.

Influence of Rake on Machine Steel. The results of fourteen experiments are shown graphically in Fig. 8. The noticeable consistency in the spacing of the pairs of values given as results of the zero rake cutter is due to the second three having been taken in a different part of the block from the first three. The results show the decided advantage of rake. The advantage of heavy chips is also clearly shown except in the case of the 20-deg. tool.

The authors do not draw any conclusion regarding this exceptional case as the experiments available are too few. In general, there is conclusive evidence that heavy chips are more economical of power than small chips, within the practical limits of present-day milling practice. The exact extent of this economy cannot be stated at the present state of the art. It is certain, however, that this condition is a function both of the material and of the rake. The influence of rake appears to depend largely on ductility.

The area under each curve gives a numerical representation of the average production of each tool over a certain region of chip weight. Taking the 0-deg. rake tool as 100, we have:

Production of 0-deg. rake tool = 100
Production of 10-deg. rake tool = 130
Production of 20-deg. rake tool = 176

Influence of Rake on S.A.E. 3240 Alloy Steel. The results of

twelve experiments are shown in Fig. 9. Again taking the area under the curve to represent the productivity, we obtain:

Production of 0-deg. rake tool = 100
Production of 10-deg. rake tool = 130.5
Production of 20-deg. rake tool = 137.5

In this case the advantage of rake is not so decided as with the more ductile machine steel, particularly above 10 deg. In addition, the same tendency is observed to reduce the advantage of thicker chips with a high rake.

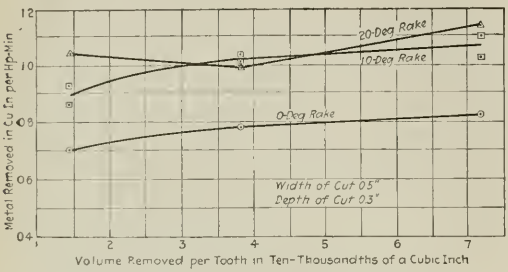

Fig. 9 Influence of Rake in Cutting Alloy Steel

Influence of Depth of Cut. Thirty-five experiments were run with various depths of cut, various feeds, and two different rakes. Analysis of these results gave rise to a belief that the block of material used was far from homogeneous. These experiments are not recorded in detail for this reason. It is advisable, however, to record certain impressions obtained and tentative conclusions.

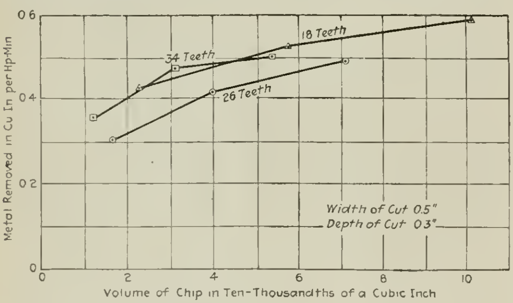

Fig. 10 Effect of Varying Spacing: Alloy Steel

If the material removed per hp-min. be plotted on a chip-volume base, then a shallow cut gives a curve higher than a deeper cut. This is not surprising. It has been shown that, as a chip thickens, the material is removed with less energy per unit volume. If two chips of equal volume but of different depths of cut be taken, then the chip of the shallow cut is shorter and thicker.

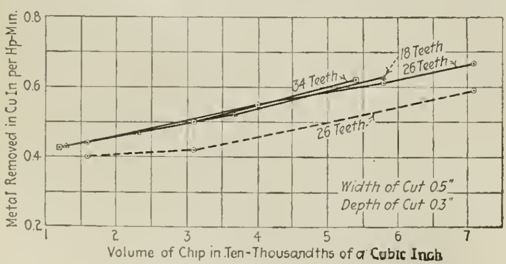

Fig. 11 Effect of Varying Spacing: Machine Steel

It appeared probable that, with a given cutter and uniform material, if the feed per tooth and depth of cut were varied, the number of cubic inches per hp-min. would prove to be a definite function of maximum chip thickness. Experimental verification of this is given later in the paper.

TABLE 1 EFFECT OF LUBRICATION

Milling Cutter: Clearance angle, 5 deg.; rake angle, 10 deg.; spiral angle, 0 deg.; diameter, 6 in.; number of teeth, 34; depth of cut 0.3 in.; width of cut, 0.5 in. Material: Alloy steel No. 10

Exp. No.	Feed in. per min.	Speed r.p.m.	Vol. per Tooth cu. in.	Torque, in-lb.	Cu. in. per hp-min.
1026 Oil	0.92	27.9	0.000145	306	1.018
1026 Dry	0.92	27.9	0.000145	364	0.855
1027 Oil	2.36	27.9	0.000375	760	1.070
1027 Dry	2.36	27.9	0.000375	875	0.930
1028 Oil	3.10	19.3	0.000710	1335	1.148
1028 Dry	3.10	19.3	0.000710	1430	1.071

Influence of Lubricant. The results of six experiments, which merely touched the fringe of the effect of lubrication, are given in Table 1. It is dangerous to generalize too broadly from a few results, but one can at least conclude that lubrication effects a reduction of energy and that this reduction appears more pronounced in light cuts. It should be again noticed that this is almost pure lubricating action and that the conduction of heat by the oil plays only an insignificant part.

Effect of Spiral. A 34-tooth non-spiral cutter 6 in. in diameter and having a 10-deg. rake was run in comparison with cutters similar in all respects excepting that they possessed a $12^1/_2$-deg. spiral angle. Two cutters with left- and right-hand spirals, respectively, were used in combination, thus eliminating end thrust. Two different combinations of speeds and feeds were used. The material cut was machine steel. The results were as follows:

R.p.m.	Feed, in. per min.	Cu. in. per hp-min. 0-deg. spiral	Cu. in. per hp-min. $12^1/_2$ deg. spiral	Lost output of spiral cutter
28.1	0.92	0.422	0.338	20 per cent
16.1	0.92	0.568	0.458	19.4 per cent

The authors are well aware that a general belief exists in the superior power efficiency of spiral cutters. Frequent statements to this effect can be found in the literature of the subject. In this investigation it has been impossible to substantiate these. It is difficult to understand the growth of the belief that spiral cutters are more efficient, because abstract analysis leads to the conclusion that spiral cutters must be inferior to straight cutters. By "inferior" the meaning intended is in reference to power efficiency only. The use of a spiral angle is heartily recommended, for it results in continuity of action, tends to avoid chatter, and keeps the driving power more smoothly constant. The smallest angle consistent with smoothness of action should be used.

Theory of Tooth Spacing. Opinions differ on the influence of tooth spacing or, in other words, the relative merits of coarse-tooth compared with fine-tooth cutters. Many cutter manufacturers standardize two types, the fine-tooth cutter and the "high-powered" cutter. Experiments have been published purporting to show the advantage of coarse-tooth cutters. Possibly many others have been made and have probably convinced the experimenter that the claims made were justified.

There is an interesting delusion in this subject and it is unfortunate that it has held sway for so long, for it has resulted in inefficient types of cutters being used. Most of the so-called high-powered cutters today on the market would be improved if more teeth were given.

It has been demonstrated earlier that the force required to remove metal does not increase in proportion to the chip thickness. It follows directly from this (and has been independently demonstrated by the Thrust and Torque Measurer) that as feed is increased the force will not increase in proportion.

Another way of stating the last paragraph is that the heavier the chip the more metal removed per hp-min. If one were to make a comparison of two cutters with different numbers of teeth but run at the same speed and feed per minute, then obviously the cutter with fewer teeth would remove the metal with less power *because the chips are thicker*, there being fewer teeth cutting per minute for the same amount of metal removed. It appears illogical, a priori, to suppose that the force action of a single tooth under any given set of conditions should be influenced by the location of neighboring teeth, *if free cutting is in operation.* This view is fully substantiated by experiment.

ness as with the coarse tooth cutter), *then exactly the same cubic inches per hp-min. would have been removed as were removed with the coarse-tooth cutter, and more actual cubic inches of material would have been removed per minute, provided the limit of machine power had not been reached.*

If comparative tests had always been analyzed from the point of view of chip volume (or maximum chip thickness, if the depth of cut varies), then the unmerited virtue of wide spacing would never have been recognized.

Three 6-in. diameter side mills were taken, 0.5 in. thick and with 10 deg. rake. They had respectively 34, 26 and 18 teeth. Various tests were run in alloy steel and in machine steel. The results of these experiments are plotted in Figs. 10 and 11.

Experiments with the same cutter are joined by a line. In both figures the 34-tooth line and the 18-tooth line came superposed within experimental error. The 26-tooth line came roughly parallel but lower in both cases. This appeared to establish the equality of cutter efficiency in the case of the 34- and 18-tooth cutters with different tooth spacings when given equal chip volume. The distinct inferiority of the results with the 26-tooth cutter to the results of both the others suggested some defect in the cutter. It was found that the side clearance was almost nil.[1] This was remedied and the tests were repeated in machine steel with the result that the 26-tooth line coincided on the left with the two others. On the right there is a slight separation due to experimental error, but no consistency can be traced. The experiments with the 26-tooth cutter were not repeated in alloy steel, as that particular block was not available.

In a paper[2] presented at the 1911 Spring Meeting of the Society by Mr. A. L. De Leeuw, claims were made regarding the superiority of wide spacing. This publication caused coarse-tooth cutters to increase in favor. If the experiments there recorded were to be compared on a chip-volume basis, the different cutters would

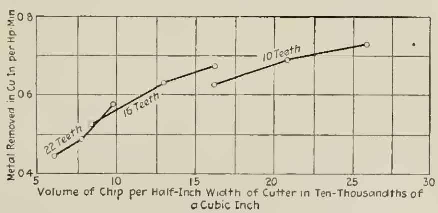

Fig. 12 Cincinnati Milling Machine Company's Experiments

doubtlessly lose their separate identity from an efficiency standpoint. As the speed of cutting is not recorded in these tests, it is not possible to find the chip volume, and so effect this comparison.

It is equally effective, however, to analyze data extracted from A Treatise on Milling and Milling Machines, issued by the Cincinnati Milling Machine Company. On page 147 of that work results are given of tests with cutters of 22, 16 and 10 teeth, respectively. These results are there submitted as establishing conclusively the superiority of the coarse-tooth cutter. The data in question are reproduced in Fig. 12, the chip volume being calculated for 0.5 in. width of cut, to make the results comparable with the others in this paper.

These results are seen to follow the same basic law as others already given. To summarize: Material and depth of cut remaining constant, the efficiency with which the metal is removed is determined solely by the chip volume and is independent of the number of teeth in the cutter.

If in using a fine-tooth cutter the feed be increased in order to give the same weight per chip as was given in a comparative test

[1] Most tests in the present section consisted in cutting grooves 0.5 in. wide and 0.3 in. deep with a side mill. It was repeatedly shown that power consumption was not affected whether the cut happened to be a groove or a land, except in this one case of side-clearance trouble.

[2] Milling Cutters and Their Efficiency, Trans. Am.Soc.M.E., vol. 33, p. 245.

b The limitation of power of machine might be reached

c The limit of structural strength of the cutter might be reached.

Condition (*a*) is very apparent, for the efficiency rapidly drops to zero as soon as chip room becomes too small. This is proof that the spacing is inadequate, a condition which doubtlessly frequently existed formerly. Condition (*b*) is probably the indirect cause[1] of existing opinions regarding wide spacing of teeth.

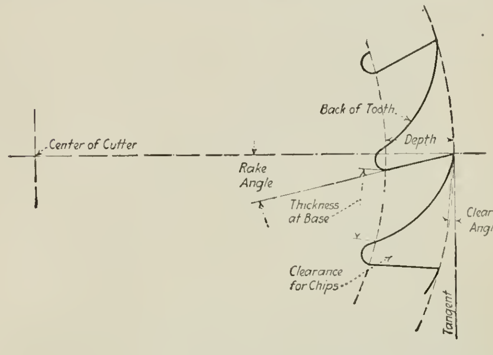

Fig. 13 Definition of Terms

If in given tests equal chips are taken, then the cutters will remove metal, the volumes of which per minute will be in the ratio of the numbers of teeth, and will of course call for correspondingly more power. Condition (*c*) would occur in the case of exceptionally thin cutters or of unusually deep cuts.

As many teeth as possible should be put into a cutter consistent with sufficient chip clearance. It is evident, of course, that sufficient excess chip space must be provided in a new cutter to allow for a reasonable amount of grinding. As soon as the necessary chip clearance is exceeded, possible economy is forfeited. A glance at existing high-powered cutters is sufficient to show that several times the necessary chip clearance is nearly always furnished.

The cuts taken in our experiments are throughout in an everyday production region. The Thrust and Torque Measurer was not capable of carrying spectacular cuts. However, that the same law holds in the region of heavier cuts, is proved by experiments plotted in Fig. 12, as they form a similar curve. Further, a study of these curves shows that chip congestion did not play any part with even the finest-toothed cutter, for this would have resulted in the last spot falling below the general trend of the combined curve.

Considering that the whole subject of milling action centers about the action of a single tooth, it appears desirable to think in terms of this. The authors take this opportunity of suggesting to milling-machine manufacturers that this point of view be encouraged in supplying instruction data with machines. As it is, the feed is invariably given in inches per minute.[2] This is useful in checking up the time required to do a given job after the feed is known. It is of no direct value, however, in checking up whether the feed is adequate for the work, because this is determined fundamentally by a definite feed per tooth.

Further, the feed per tooth is a function of the material and of

[1] See later paragraph entitled General Consideration of Removing Metal by Milling.

[2] The present practice is to give feed in inches per minute with machines having a constant-speed feedshaft. Feeds are given in inches per spindle revolution with machines having the feed train driven from spindle. Recent literature indicates that doubt exists regarding the relative merits of the two systems. The problem is purely and simply that of obtaining the greatest range with the simplest mechanism. The authors believe that the constant-speed feedshaft is unqualifiedly the better of the two systems. They further believe that this lends itself to a demonstration as rigorous as a proposition in Euclidean geometry does. For discussion of this, see letter in Mechanical Engineering, March, 1921, p. 207, by John Airey, on Milling-Machine Feed Systems.

the depth of cut. Data should be arranged so far as possible to focus attention on the maximum chip thickness. This is the basic criterion of effort from the cutter standpoint.

The authors believe that in a few years, by coöperation between milling-machine and milling-cutter manufacturers, data and practice will have evolved so that a set-up man will determine the appropriate chip thickness and then, by reference to tables, will set the speed and feed to give this. The feed per tooth for a given cutter determines the feed per revolution of spindle. If a chart were supplied giving the feed per revolution for all possible combinations of speeds and feeds, then this would be of direct use in working from a feed-per-tooth starting point and would constitute the first step in the suggested direction.

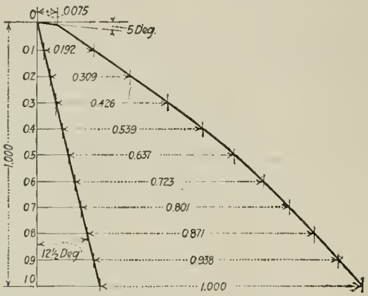

Fig. 14 Ideal Shape of Tooth

General Consideration of Removing Metal by Milling. It is an interesting and profitable line of thought to consider, in its broadest phases, the problem of removing metal by milling. The first factor to be considered is chip thickness. In order to remove the maximum amount of metal per hp-min. the chips should be as thick as possible.

The chip weight is limited by the endurance properties of the cutting tool, as is also the cutting speed, which is the second factor to be considered. Various experimenters in lathe-tool action have shown that, for a given tool, the chip weight and the cutting speed are interrelated. It should be remarked here that the degree of bluntness permissible in a milling cutter is very slight, when compared with the allowable bluntness of a continuous-cutting tool.

The greatest metal-removing capacity occurs when the product of chip volume and cutting speed is at a maximum. Let us assume that the most advantageous combination of speed and thickness is known for a given tool and material, so that these factors may be kept constant. It then follows that the closer the teeth are together, the more metal will be removed per minute, provided, of course, that the spacing of the teeth is not so far reduced that clogging of the chips takes place. Since power efficiency is determined by chip thickness only, it is evident that this is not altered by varying the tooth pitch.

If it is possible to keep the feed per tooth constant and decrease the tooth spacing without exceeding the power of the milling machine, the ideal conditions are achieved, i.e., the maximum volume of metal is removed per minute with the expenditure of the least possible power. Suppose, however, that the limit of the machine's power is reached before the minimum possible tooth spacing is obtained.

The problem now assumes a different aspect. We have already obtained the maximum power efficiency by virtue of using the thickest possible chip. If the tooth spacing is to be decreased, the power of the machine will be exceeded unless some of the other factors are changed. If the feed be reduced, the chip becomes thinner. This results in a decrease in the power efficiency coupled with a decrease in the amount of metal removed per minute.

Suppose that we leave the feed constant, decrease the tooth spacing, and at the same time reduce the spindle speed so that the feed per tooth remains the same. The power efficiency will then remain constant, as will the amount of metal removed per minute. Furthermore, the decrease in peripheral speed will result in a lengthening of the life of the cutter between grinds.

We have thus demonstrated a priori that fine spacing is superior to coarse spacing, regardless of whether the cutting speed or the power of the machine be the limiting factor. In the first case, the fine-toothed cutter will remove more metal per minute. In the second case, the fine-toothed cutter will wear longer between grindings, due to the decrease in cutting speed.

Shape of Tooth

The following six features of a tooth will be discussed:

a Clearance	*d* Depth
b Rake	*e* Thickness of base
c Shape of back	*f* Clearance for chips.

These features are defined in Fig. 13.

Clearance. Excessive clearance does not reduce the cutting force, does not appreciably affect the life of the tool in normal wear, but does tend to chattering action; also it weakens the cross-section near the cutting edge and increases liability to snip. Clearance should therefore be kept to a minimum. Three degrees was found to be ample but 5 deg. was usually used. In many tool cribs it might be desirable to standardize at 8 deg., due to the possibility of an error of a few degrees. In practice it is customary to speak of clearance in thousandths of an inch at the heel of a land. This is obviously a safer method, as the heel might bind for any given clearance angle if the land were sufficiently extended. However, for scientific analysis it is better to use degrees.

Rake. From a power-consumption standpoint rake is increasingly beneficial as it becomes greater. The advantage of rake, though, does not increase at so fast a rate after about 15 deg. is passed. Further, this is influenced by the kind of material being cut. On the other hand, the life of the cutter might be influenced disadvantageously by excessive rake.

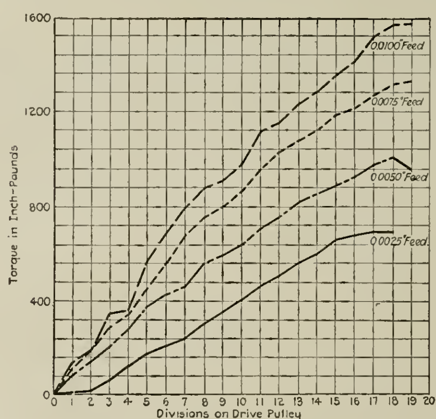

Fig. 15 Statical Experiments on Four Different Chip Thicknesses

It is believed that the greater the rake, the longer the life, from a simple abrasion standpoint. An increase in rake, however, necessitates a decrease in the heat conductivity of the tooth, as a consequence of which increased wear due to rising temperature is more likely to occur. A compromise can be obtained only by experiments on endurance and this is treated later.

While the decided power advantage afforded by rake is indisputable, it is not advisable to jump too far in the higher regions. Had the importance of developing cutter design in this direction been acted upon decades ago, as it should have been, then we should be on a much safer footing, as a considerable amount of data would have been available regarding action of greater rakes in all types of situations.

Under the circumstances, the authors believe and recommend that cutters be given 12½ deg. rake; further, that for any definite job it might be very desirable to go beyond this, even as high as 25 deg., but that 12½ deg. may safely be taken as a minimum, with the possible exception of rare and unusual job.

-chip room or deleteriously increasing tooth spacing. An ideal tooth shape is given in Fig. 14, with construction data.

Depth. The depth is controlled partly by the length of grinding life expected, but chiefly by the spacing, which in turn will be shown to depend on chip clearance. It is not possible by any method of calculation to predetermine the chip space necessary for given conditions of cut. The space actually needed is a function of the shape of the chip, depending on just how tightly it rolls, manifestly a condition not lending itself to computation.

This feature can be determined only by experiment, but one fact should be kept clearly in mind in considering this, viz., that the shape of the space between teeth is equally important with its net area. The shape should be such as to prevent the chips from "packing," for this quickly causes the power to increase abnormally. Narrow, wedging bottoms must be avoided. The prevention of packing is facilitated by a spiral cutting edge; it is less liable to occur in thin cutters than in thick ones.

Thickness at Base. For a given depth, the thickness at the base is controlled by the ability of the tooth to resist fracture. This is, in turn, dependent on the quality of steel. Thickness at the base is taken as equal to depth in the recommendation here given. This is fairly consistent with present practice and gives an ample factor of safety for cuts that are customary.

Clearance for Chips. Chip clearance should be sufficient to accommodate the heaviest cut that is desired to take, and no more. It has previously been shown that if clearance is more than necessary or if the cutter is used for chips smaller than the maximum possible, then metal-removing possibilities are being

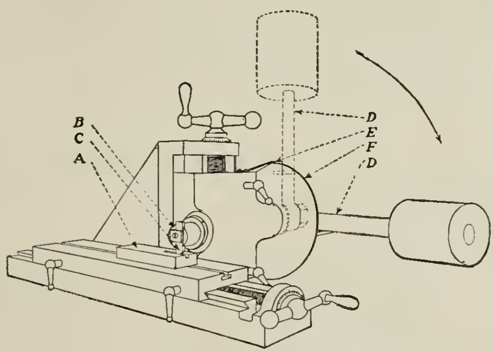

Fig. 16 Machineability Tester

sacrificed. Chip-clearance requirements govern the spacing, and this in turn fixes the number of teeth in a cutter for a given diameter.

Design Formulas. Formulas for determining the number of teeth for a known diameter of cutter and for determining the depth are given below, and a geometrical construction for obtaining shape of tooth has been given in Fig. 14. The arguments demonstrating the rationality of these are given in an appendix to the complete paper.

Let n = number of teeth

R = radius of cutter in inches

d = radial depth of straight face in inches

then

$$n = 19.5\,R^{1/2} - 5.8$$
$$d = 0.215\,R^{1/2}$$

A Statical Study of Single-Tooth Action

Objections will doubtlessly be raised to the use of statical experiments, due to the supposed discrepancy between cutting action at a dead-slow speed or in installments, and cutting action at a customary speed. The authors believe this discrepancy to be more imaginary than real and that considerable information can of which are at hand, was to find if instantaneous chip thickness is the sole criterion of force at a given instant. In the early part of this work the habit was formed of thinking in terms of chip volume. It was believed that this was the basic starting point for correlation of results; and so long as depth of cut was kept constant, there was no reason to question the legitimacy of this viewpoint.

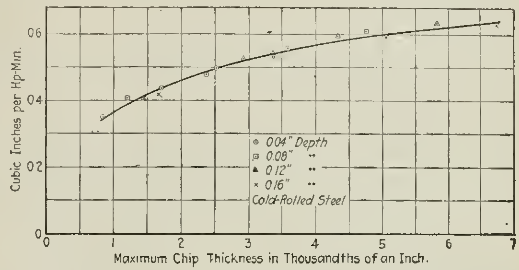

Fig. 17 Metal Removed as a Function of Maximum Chip Thickness

As stated in an earlier paragraph, the work done with various depths of cut was of doubtful value. Nevertheless, it was apparent that shallow cuts showed up more favorably on a chip-volume basis. This led to further speculation, ending with the conviction that not chip volume but maximum chip thickness was the feature of basic interest.

The truth of the above statement seems so obvious when the action of milling is carefully considered, that the fact would not be elaborated on, were it not that months of experimental work had been done before this idea developed. All chips, to within a small error of mathematical interest only, increase uniformly from zero thickness to a maximum. As any given instantaneous thickness of chip connotes a certain force action at that instant, and as the increase in thickness is uniform, it follows that the maximum chip thickness is a unique criterion of the material removed per horsepower-minute for a given cutter and material.

On this assumption a miscellaneous set of experiments with constant material and constant shape of cutter tooth would fall on one curve, if metal removed per hp-min. be plotted against maximum thickness. The variation in depth of cut and the varying tooth spacing would have no influence.

Comparison of Four Chips of Varying Feed. A cutter of 10-deg. rake was used, the depth of cut taken was 0.30 in. and the feed was taken successively as 0.0025 in., 0.005 in., 0.0075 in., and 0.010 in. The feed was obtained by carefully moving the table by hand and then locking the gib screw. The rotation of cutter necessary just to take one chip was divided into 20 equal parts and readings were taken.

The results are shown graphically in Fig. 15, the torque being plotted against divisions of the driving pulley. The same general shape is observed except in the case of the 0.0025-in. chip. Several attempts were made to obtain consistent results with this without much success. A little reflection on the probable distortion of results produced by the knee bracket being, say, 0.0002 in. too high or too low on a thin chip like this will account for this difficulty.

Endurance Tests Under Commercial Conditions

Although increasing the rake angle is unquestionably beneficial from a power standpoint, the same is by no means obviously true from the standpoint of endurance. In fact it is apparent that a continuous increase of rake must ultimately jeopardize endurance.

To investigate this, numerous experiments were necessary and arrangements were made to make them under commercial conditions.

As a result of these experiments it was found that from an endurance standpoint rake is certainly increasingly beneficial up to

(Continued on page 798)

Heat Balance in Steam Power Plants

Particulars of Systems Employed in Three Large Modern Stations to Adjust Rate of Steam Generation to Demand With the Least Possible Waste of Heat and Expenditure of Coal

THE general topic set for discussion at the 1921 Annual Meeting of the Society is the subject of "Waste," which is of vital importance in this country, where there is such a widespread disregard of the conservation of its natural resources. The Power Division has been asked to confine its session to some feature of this general topic.

Much has been written concerning the design of power-generating equipment, combustion methods, and general design of power stations. Comparatively little, however, has been said concerning the heat balances that have been secured, and that may be secured, in steam power plants.

By heat balance we are here to understand that correlation of events in the heat cycle of the plant as a whole which adjusts the rate of steam generation to the demand with the least possible waste of heat, and at the least possible expenditure of coal. The securing of this proper adjustment is the problem now under consideration.

Labor-saving methods and devices have been introduced to such an extent that the cost of fuel is now by far the greatest item of expense in generating power. Improvements in steam turbines, increased efficiencies of boilers, pumps and other equipment have materially assisted in reducing this item. But it still remains the duty of the power-plant designer to design the plant and to select and install its equipment in such a way that the heat generated therein may be utilized to its fullest extent and every source of waste avoided in so far as possible, in order that this share in the reduction of fuel cost may be performed. Some methods, while apparently very efficient, have inherent losses, which can be determined only by very careful study.

There are four principal sources of heat waste with which the power-plant designer has to deal:

1 Radiation
2 Stack losses
3 Losses in condensing water
4 Losses due to excess exhaust steam.

The means which he employs to reduce these losses determine the heat balance to be secured in the operation of the plant.

With the thought that much good could result from a general discussion of the subject of heat balance, engineers from various companies have been asked to present the ideas used in the design of some of the recent stations.

Intimately involved in the solution of the heat balance is the method employed for driving the station auxiliaries. In the early plants they were driven principally by means of steam engines of high water rates. Improvements in steam-engine design and the introduction of high-speed turbines gradually increased the economy of the steam-driven auxiliary system; later the electric motor, both alternating- and direct-current, found favor with the designers. Today there are advocates of many systems of auxiliary drive. Some engineers prefer to use only steam drive, others alternating current, some direct current, and many favor combinations of steam and motor drive.

The systems used in the stations dealt with in the following papers are the embodiment of the ideas of their respective designers as to the best methods of properly working out the heat balance for these stations.

The Power Division desires a thorough discussion of the subject and invites the members to express their views thereon without necessarily confining themselves to the systems described in the papers. They are presented for the purpose of starting a general discussion on this very broad subject, which is of paramount importance to the designers and operators of steam power plants. While the systems described in the following papers are those used in large stations, the ideas contained in them might well be applied to stations of moderate size.

Auxiliary System and Heat Balance at the Delaware Station of The Philadelphia Electric Company

By E. L. HOPPING,[1] PHILADELPHIA, PA.

FOR the past few years the high cost of fuel and other materials used for the generation of electrical energy, together with the high cost of labor for operation, has made it imperative that the maximum economy should be obtained in the use of materials and labor entering into the construction and operation of the public-utility company's steam-electric generating stations. The greatest economies are to be found in the efficient burning of the fuel for steam generation and in the proper utilization of the energy contained in the steam. There are various factors entering into the problem in connection with the auxiliary system and heat balance for any of the large generating stations that must be considered. Any decision regarding the auxiliary system and heat balance involves the consideration of certain outstanding conditions, which may be classified in the order of their importance as follows:

a Reliability of service
b The economy in heat units per kilowatt of net output
c Simplicity and flexibility of operation with which the heat balance may be maintained under widely varying conditions of load and temperature
d The flexibility of the system in view of possible future developments and changes in power-plant equipment
e The investment and maintenance cost of the equipment used in obtaining the desired economies, and its comparative value to other systems in terms of income from the investment.

In working out the auxiliary system and heat balance for the Delaware Station of the Philadelphia Electric Company, the factor of reliability of service was considered of prime importance, and of somewhat greater value than that of heat economy. A study of the system will indicate its flexibility and its value in meeting varied conditions or varied temperatures in boiler feedwater which might be obtained with the installation of apparatus such as air extractors.

It has always been considered by this company that the small comparative cost of duplicating the main generating unit auxiliaries is fully warranted in view of the resulting ability to keep a large unit on the line in case of failure of any of the different auxiliaries connected with the unit. This particular item is one which must be considered almost entirely in the light of reliability of service, since no direct returns on the investment can be shown by the installation of duplicate auxiliary equipment.

Having the question of duplication of auxiliaries decided, the next step was to settle upon the method of driving the various auxiliaries in the plant. Due to temperature changes in the circulating water, the vacuum on the main generating units varies from about 28 in. during the summer months to 29.25 in. during the winter months. Temperature charts of this water condition show average variations of from 40 to 80 deg. fahr. With this variation in vacuum there must be considerable flexibility in the method

[1] Mechanical Engineer, The Philadelphia Electric Company. Mem. Am.Soc.M.E.

A group of papers to be presented at the Annual Meeting, New York, December 5 to 9, 1921, of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS. The papers are here printed in abstract form and copies of the complete papers may be had upon application. All papers are subject to revision.

of the feedwater to the required point, which in this case, up to the present time, has been 210 deg. fahr. Knowing the amount of heat required under varying vacuum and load conditions, it remained to select such auxiliaries to be steam-driven as would furnish the required heat through their exhaust. It was found possible to obtain this result by installing turbine drive on one of each of the duplicate auxiliary pumps connected with the main generating units, together with turbine drive on boiler-feed pumps and on one house pump. It was, however, found necessary at times of heavy load and high vacuum to supply a certain additional amount of heat, which was obtained by bleeding the main turbine at the eleventh stage.

All of the boiler-feed pumps are turbine-driven. This practice has been followed throughout the system of the Philadelphia Electric Company and has been made standard, based upon the fact that in case of a serious disturbance in the electric system of a particular plant, the boiler-feed pumps would not be affected. At such a time it is very necessary that these pumps be available for duty.

The forced- and induced-draft fans and the stokers are motor-driven and receive their current through a station light and power system. These auxiliaries and their protective equipment, described more fully later in the paper, would be shut down only in case of an interruption of the service to the two buses of this system.

On each of the main units one of the two circulating pumps is installed with a duplex (steam and motor) drive. By use of this type of drive two results are obtained:

a A flexible unit is available, which, by varying the load on the turbine drive, will supply the required heat variation for maintaining a practically constant feedwater temperature

b In case of trouble on either the steam supply or the electric service, the opposite drive will automatically pick up the load, and thus keep the condenser water in circulation. The other circulating pump, which is provided with a motor drive only, is used as a reserve, or in case it is desirable to operate two circulating pumps at a time when high circulating-water temperatures occur.

For the air and condensate pumps a duplex drive is not deemed necessary, as, in case of trouble with either of these auxiliaries, a brief shutdown would not be serious. If one of the pumps is in trouble, it only requires a very short time to put the other pump in service. During this time the vacuum, in case of an air-pump failure, should not be affected to any appreciable extent, and the condensate storage capacity in the condenser would take care of the time element in getting the other condensate pump on the line.

Throughout the plant apparatus such as coal hoists, conveyors, miscellaneous pumps, etc., is motor-operated. This equipment is all for intermittent service, and a brief shutdown of any piece of apparatus would not affect the plant system. In only two cases have we installed turbine drive on miscellaneous pumps. These are in the case of the fire pump and the house water-service pump. Turbine drives were installed on duplicate pumps in these instances in order to protect the plant should an interruption to the electrical service occur.

Electrical System

While considering the extensive use of electric drive for auxiliaries, it was clearly realized that it would be unwise to take advantage of the economies thus made possible, unless the reliability of this supply and the sturdiness of the equipment was comparable to steam drive. In order to insure this, four considerations were kept in mind in the design of the station light and power system:

a Great care must be used in the selection and layout of the equipment, so as to give a high degree of reliability

b In case of trouble on the system any defective piece of apparatus must be isolated immediately with the minimum effect on other apparatus

c Any apparatus whose operation might have been interfered with must be restored to service as quickly as possible, with the minimum of attention by the operating force

d Any disturbance on the main generating system must have a minimum effect on the station light and power system.

The electric load was found to be of such proportions that had and losses would have been very great. This consideration led to the adoption of 2300 volts for the supply of the larger motors. Though there was no definite experience available on which to base such a course in central-station practice, the economies thus effected, together with the improvements which had been made in 2300-volt equipment, resulted in the use of this potential for motors of 100 hp. and larger. Since ruggedness and reliability are essential for service on boiler and turbo-generator auxiliaries, it was recognized that great care must be exercised in selection of the 2300-volt equipment. With these thoughts in mind, features such as especially rugged contactors, both primary and secondary, for slip-ring motors, increased spacing of slip rings, 40-deg. cent. ratings, and oversize starting compensators were included in the specifications.

In the design and construction of the 2300-volt station auxiliary system the same care was exercised as in the case of the main 13,200-volt system. Bus bars and oil circuit breakers are housed in concrete compartments, and breakers of high rupturing capacity used. By the use of differential relays on all of the important motors, assurance is given that the latter will not be disconnected from the line for any reason other than failure within themselves or of the cable supplying them, thus insuring continued operation during system disturbances. The motors used with the boiler fans and circulating pumps are so arranged that, in the event of an interruption to service, they will automatically be restored to the condition of operation existing previous to the interruption.

It was recognized that boiler-room attendants, and even turbine engineers, would probably not be familiar with electrical equipment, and for this reason and for greater reliability of operation all apparatus is of the remote-control type. Hand-reset relays in locked compartments are employed, so that it will be impossible for any one but the plant electrician to restore service to a motor that has failed, and more than ordinary precautions are taken in enclosing all electrical equipment that is located in the boiler and turbine rooms.

While only two units are at present installed, the capacity of this plant has been planned for an ultimate installation of six 30,000-kw. generating units, and the electrical distribution as described below will take care of the complete installation.

The electrical supply to auxiliaries will be through four 5,000-kva. 13,200 to 2,300-volt transformer banks. Three of these are ample to carry the ultimate peak load. This energy is distributed to the various auxiliaries through twenty-eight 2300-volt feeders as follows:

9 feeders to circulating- and air-pump motors
8 feeders to boiler-fan motors' distributing bus
2 feeders to coal tower
2 feeders to motor-generator sets for d. c. supply
1 feeder for motor-driven exciter
2 feeders to miscellaneous motors' distributing bus
3 feeders to low-tension transformers
1 feeder to test set (for testing high-tension cable)

There will be three 1000-kva. transformer banks for stepping the voltage from 2300-volts three-phase down to 115–230-volts two-phase to supply small motors and lighting. There will also be two 300-kw. motor-generator sets to convert a. c. energy to 125–250-volts d. c. for driving motors of wide speed variation, such as those used for stoker drive. A storage battery serves as an emergency supply for this equipment.

Most Economical Heat Distribution

Two heat-distribution diagrams, Figs. 1 and 2, have been worked out, based on the present installation of two 30,000-kw. generating units. Fig. 1 illustrates the heat distribution for an hourly load at the most economical point of operation for the turbine, and with a vacuum of 29 in. Nearly all of the values shown are based on the results of actual tests conducted on the apparatus since its installation, and the coal rate has been based on a heating value of 13,500 B.t.u. per pound of coal as fired. At the time the heat balance for this plant was originally calculated, coal received contained an average heat value of 13,500 B.t.u., as used in this figure. This value has been used in calculations for all preliminary, or theoretical, heat balances.

The overall efficiency of the boiler, stoker and economizer of 80.4 per cent, given on Fig. 1, is based on an actual test made during the month of June, 1921, when an efficiency of 81.7 per cent at a boiler rating of 176 per cent was obtained. A correction has been made on this diagram for the lower air temperature that would prevail during the winter months, at which time a vacuum of 29 in. is obtainable.

Under "heater vent losses" has been included a loss of about 5 per cent of the exhaust steam used for feedwater heating. This loss would be difficult to measure with any accuracy, but it is believed from rough checks on heat absorbed in feedwater that the figure of 5 per cent should cover the losses at this point. The economizer and blowdown losses are correct within the limit of accuracy of the V-notch meter used to record these losses.

The item of line radiation losses, while apparently small, is noted separately, due to the fact that this is a heat loss only. When the original heat balance was figured for this plant, it was felt that it would never be necessary to bleed the turbine, due to the fact that a large increase in temperature of the condensate was expected as a result of passing the condensate through the waterbacks in the boiler bridge walls. It was found, however, in actual practice that, due to the very large combustion chamber and the more complete combustion secured therefrom, the temperature rise of the water was almost one-third less than that originally estimated.

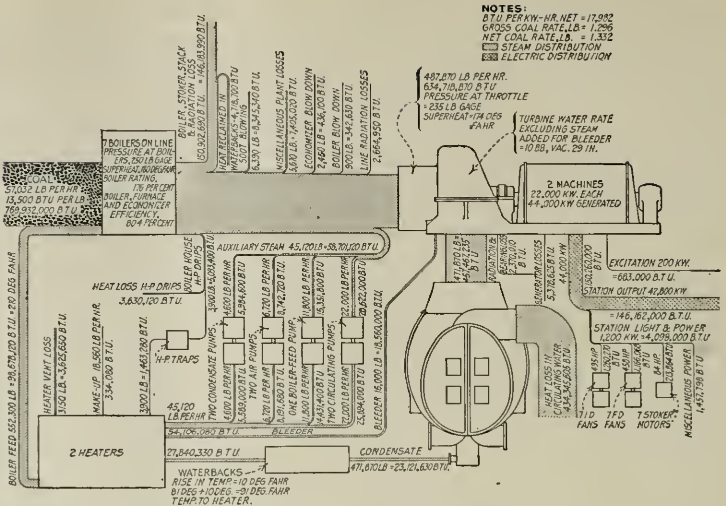

FIG. 1 HEAT BALANCE AT MOST ECONOMICAL LOAD
(60,000-kw. generating station with 44,000-kw. load and 29-in. vacuum.)

The heat distribution for the hourly condition (Fig. 1) does not of course, make any allowances for banking or emptying of boilers for repairs. These are about the only losses which would occur over continued operation, which is not included in this diagram.

TYPICAL WEEKLY HEAT DISTRIBUTION

Fig. 2 illustrates the actual heat distribution over a period of one week, during April, 1921. It will be noted on this diagram that the load factor of the plant, based on its maximum capacity, was only slightly over 50 per cent, which means, in this case, that the average boiler efficiency is lower, and the average turbine water rate higher, than will be obtained under more favorable load conditions. Several records of weekly coal rates which very nearly approach this result have been obtained with a lower load factor and the plant operating over considerable periods of the day with light loads on the turbine.

There are several items on this diagram which differ from the diagram in Fig. 1, as follows:

a A considerable difference will be noted between the heat value of the coal as used in this diagram and that used in Fig. 1. The coal was comparatively high in heat value during this week's operation, whereas the average over a longer period would be lower

b All of the turbine-driven condenser auxiliaries have been grouped, as the number of auxiliaries used in varying conditions necessarily varies with the load and temperature

c The station light and power load has also been given as one item, due to the fact that the number of auxiliaries in service at various times depends on the load and temperature

d There is no temperature increase shown in the condensate between the condenser and the heaters, as the water backs had not been connected to operate on condensate at that time. The heat which ordinarily would be picked up in the condensate water in this case was lost and is accounted for in the stoker and radiation losses

e The average boiler-feed temperature at this time (for the diagram in Fig. 2) was 204 deg. fahr. It was found in operation that this temperature is too low, and that not enough oxygen is liberated in the heaters to allow for operation of the boilers without considerable pitting in the integral economizer tubes

f The amount of superheat in the steam at this time was lower than shown on the diagram in Fig. 1, due largely to the fact that, with the combustion conditions obtained in the large furnaces, the superheat was below guarantees. Since that time the superheat has been increased by changes in baffling, with resulting increase in efficiency on the turbine water rate.

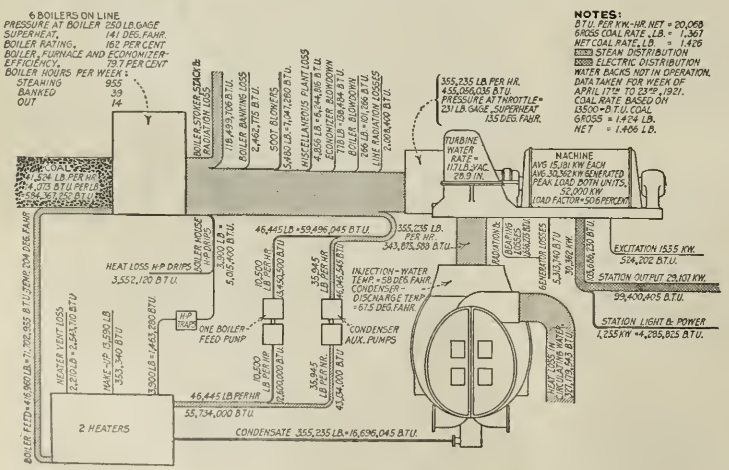

FIG. 2 HEAT BALANCE FOR ONE WEEK'S OPERATION
(60,000-kw. generating station having average load of 30,362 kw. and average vacuum of 28.9 in.)

Throughout the week illustrated in this

over the week end, when the station load is usually low enough to be carried on one turbine, one boiler was taken out for repairs and cleaning. The banking hours represent the hours during which certain boilers were banked to take care of low-load conditions between midnight and 6. 00 a.m. It was found more economical to bank boilers for this period than to operate the entire six boilers at a lower rating.

Summary

Summarizing the heat-balance situation at this station, it is believed that, while there may be a slight loss in heat economy as compared with some other method of obtaining heat balance, the very important item of reliability of service as obtained by this system, and the ease with which it may be operated, will fully offset the possible gains in heat economy secured by other systems.

At the present time steps are being taken toward the installation of an air extractor, which, by removal of the oxygen from the feed-corrosion due to this cause, but will increase the boiler efficiency and the overall plant efficiency by allowing us to operate with feed-water temperatures of about 140 deg. fahr.

In the operation of this auxiliary system the only points of variable control which must be taken care of by the operator are the steam supply through the duplex circulating pump and the bleeder steam. These are both, at the present time, manually operated by the regular pump-room engineers. All of the other steam-driven auxiliaries are operated to suit the larger changes in plant load and temperature conditions. These changes do not come very frequently, and are fairly regular in the time at which they occur, so that this phase of operation of the auxiliary system is of only minor importance.

The author wishes to extend his thanks to Mr. R. A. Hentz, assistant electrical engineer of the Philadelphia Electric Co., for his assistance in the preparation of the electrical features of this paper, and to the other associates in the engineering department who assisted him in assembling the data.

Heat-Balance System for Hell Gate Station

By J. H. Lawrence[1] and W. M. Keenan,[2] New York, N. Y.

The Hell Gate Station of The United Electric Light and Power Company, now being built in New York City, will have an ultimate capacity of 280,000 kw., consisting of eight 35,000-kw. turbo-generators. The initial generating installation will consist of two 25-cycle General Electric single-cylinder units and two 60-cycle Westinghouse double-cylinder units. The ultimate boiler installation will consist of 24 water-tube boilers, each having 18,900 sq. ft. of heating surface, with double stokers equipped with clinker grinders. At present one-half the total number of boilers are being installed.

The station will be operated as four independent groups, each consisting of one 60-cycle unit, one 25-cycle unit, one house alternator and six boilers, although provisions have been made for interconnecting the various groups electrically and mechanically.

In connection with the design of this station, the following systems for driving the auxiliaries were considered:

a All steam
b Steam and direct current
c Steam and alternating current
d Direct current
e Altерating current

After a careful study had been completed, it was decided to adopt the alternating current system.

All auxiliaries in this station are to be motor-driven, with the exception of one boiler-feed pump for each group, one fire pump and one of the two exciters for each house alternator. One-half the power for the auxiliaries of each group of two main units will be obtained from the main 60-cycle bus and one-half from the house alternator, so that in case of interruption of either source of power only one-half the auxiliaries will be shut down.

The house alternators will be 2500-kva. 60-cycle 3-phase 2300-volt direct-connected non-condensing machines, running at 3600 r.p.m. The power for the auxiliaries from the main station bus will be transformed from 13,200 to 2300 volts by means of two 7500-kw. power banks located in the boiler-house basement. All motors 25 hp. and over are to be operated at 2300 volts, excepting the motors for the coal towers, cranes and skip hoist, while motors under 25 hp. will be wound for 220 volts.

Any of the station auxiliaries excepting the motors on the coal towers, cranes and skip hoist may be operated from either the bus supplied by the main units or the house-alternator bus through the 2300-volt truck switches, which are located along the division wall between the turbine room and boiler-house basements. The house alternator and the bus supplied by the main units cannot be interconnected.

A diagram of the feedwater system of one group appears in Fig. 1. The condensate after leaving the condensers goes through closed heaters where it is heated to about 150 deg. fahr. and then enters the open heaters where it is raised to 210 deg. fahr. The condensate is then pumped by the boiler-feed pumps direct to the boilers.

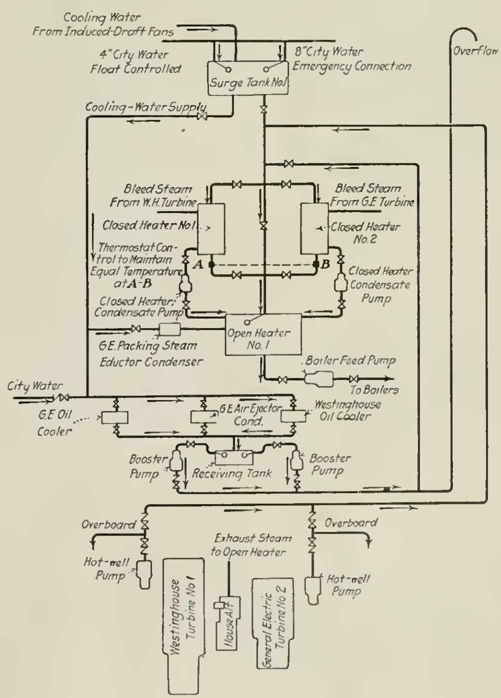

Fig. 1 Heater Connections For One Section

Thermostatically controlled valves equalize the load on the two closed heaters. The closed heaters are supplied with steam at about 6.5 lb. absolute pressure bled from the lower stages of the main turbines. The condensate from the closed heaters is pumped to the open heater. As indicated in Fig. 1, fresh water obtained from the surge tank is used for the oil coolers and air-ejector condensers

[2] Assistant to Engineering Manager, Thomas E. Murray, Inc. Assoc-Mem. Am.Soc.M.E.

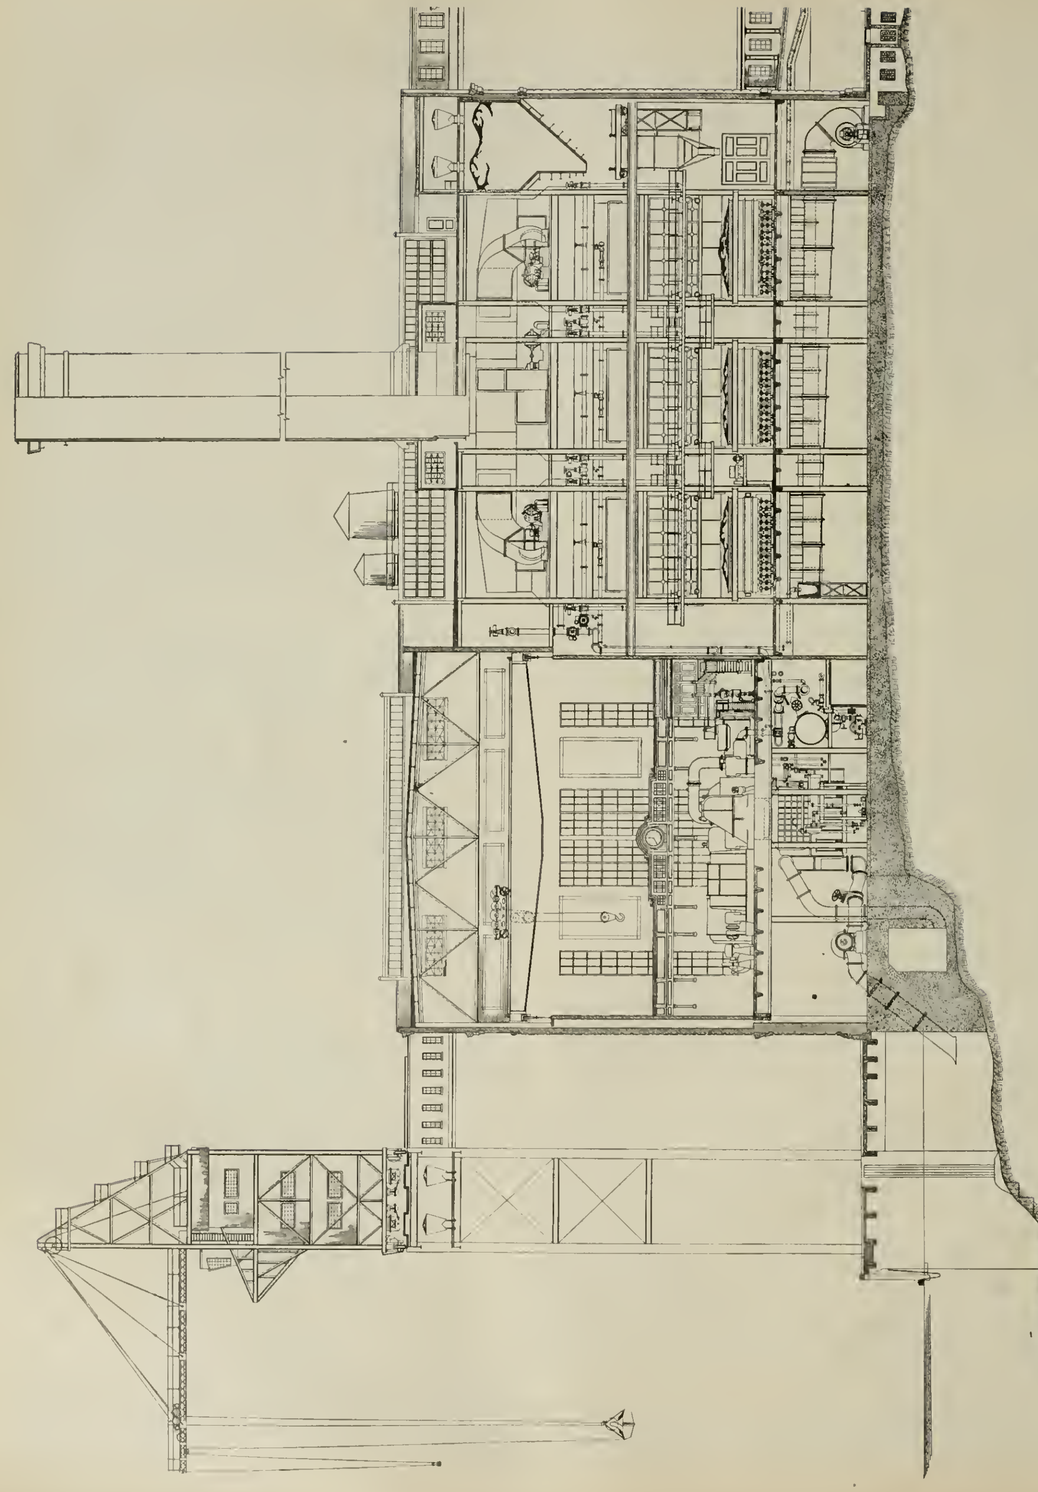

Fig. 2 Cross-Section of Portion of Hell Gate Station

the open heater. The exhaust from the high-pressure packing of the General Electric unit, approximately 4000 lb. of steam per hour, also flows directly into the open heater.

In order to insure a sufficient supply of steam to the open heaters at all loads on the house alternator, steam is bled from intermediate stages of the main turbines through pressure-control valves so adjusted as to automatically maintain 1 lb. back pressure in the open heaters.

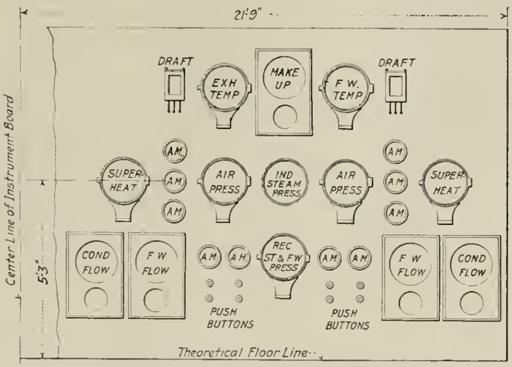

Fig. 3 Portion of Instrument Board for Mechanical Apparatus, Showing Layout for One of the Four Groups

The auxiliary control board, by which one man will supervise all the station auxiliaries, is located above the turbine-room floor. Practically the only manual regulation required for securing the proper heat balance will be the control of the forced-draft fans which will be operated by push-button switches on the control board. The induced-draft fans after being manually started are regulated by an automatic balanced-draft system.

The motors for driving the forced- and induced-draft fans will be of the brush-shifting variable-speed type. The boiler-feed will be driven by constant-speed squirrel-cage induction motors. The stokers will be driven by constant-speed squirrel-cage induction motors through variable-speed transmission machines. The clinker grinders will be driven by two-speed squirrel-cage induction motors.

Fig. 3 shows a typical layout of panel on the control board. The instruments for each of the four groups into which the station is divided are arranged as follows:

The draft gages in the top row are of the three-point type and indicate the furnace draft in each of the three boilers in each row of boilers.

The other instruments in the top row record: (*a*) the exhaust-steam temperature in the atmospheric exhaust line, in order to detect any loss due to excess exhaust steam; (*b*) the city water make-up to the group; and (*c*) the temperature of the feed-water to the boilers.

In the middle row are: (*a*) recorders for measuring the temperature of the steam at each of the main turbine throttles; (*b*) recorders showing the air pressure in the forced-draft duct leading to each row of boilers; (*c*) a steam-pressure gage for indicating the pressure in the main steam header; (*d*) ammeters for indicating the relative load on each of the induced-draft fans.

In the bottom row are recorders for measuring: (*a*) The condensate from each of the condensers; (*b*) the feedwater to each row of boilers; (*c*) by one instrument the main steam pressure and the feedwater pressure; (*d*) ammeters for indicating the relative load on the forced-draft fans.

It was the original intention to present herein the calculations made when computing the heat balance to be obtained, but after conferring with the various authors who were preparing papers on heat balance for the Meeting, it was felt that the chief interest would be centered upon operating figures, and as the Hell Gate Station is not in operation at the time this paper goes to press, operating figures are not available, and the heat balance calculated for it would therefore have only a theoretical value.

It was thought, however, that the presentation of the system to be employed to obtain the heat balance would be of interest at this time, and for this reason the present brief description was prepared. It is to be hoped that operating figures will be available for discussion at the Annual Meeting.

Heat Balance of Colfax Station

By C. W. E. Clarke,[1] New York, N. Y.

It has been the practice for a good many years to drive certain auxiliary station apparatus by steam and to use the exhaust from this apparatus for heating the feedwater. Within recent years various attempts have been made to proportion the amount of steam-driven auxiliary apparatus so as to have only enough exhaust steam to maintain the feedwater at a suitable temperature. This system has taken on many different forms, but the purpose of all of them is to avoid having any excess of exhaust steam that would have to be wasted. Systems having the foregoing object in view have received the general name of "Heat Balance System." It is not within the scope of this paper to discuss the relative merits of various types of heat-balance systems. The author will simply endeavor to explain briefly, but as clearly as possible, the system adopted for the Colfax Station of the Duquesne Light System, located at Cheswick, Pa., and give some of the results so far attained with it.

The Colfax Station is designed for an ultimate gross capacity of 360,000 kw. and for a maximum output of 300,000 kw. The generating equipment as now planned will consist of six 60,000-kw. turbo-alternators, of which one is now in service and a second in process of installation. The immediate boiler equipment will consist of seven B. & W. cross-drum boilers, each having 20,880 sq. ft. of heating surface; four others of the same type, each with 22,910 sq. ft. of heating surface, are to be installed in the near future. These boilers will be equipped with 17-retort extra long Westinghouse underfeed stokers. Each of the present units has four 25,000-sq. ft. Westinghouse surface condensers, two for each low-pressure element. All condenser auxiliaries are motor-driven. There are three 1500-g.p.m. turbine-driven centrifugal boiler-feed pumps. The forced-draft equipment consists of three 250,000-c.f.m. Greene fans, turbine-driven through reduction gears. All other station auxiliary apparatus is motor-driven. A 2000-kw. house turbine is provided to supply auxiliary power. This turbine comprises part of the heat-balance system as described below.

Fig. 1 shows the bus arrangement for supplying the electrical auxiliaries. There are two buses from which the auxiliaries may be supplied, one fed through a transformer bank from the main station bus, the other fed by the house turbine. These two buses are tied together through a motor-generator set, so arranged that energy can pass from the auxiliary bus to the house-turbine bus but not in the opposite direction. A direct tie is provided between these two buses for use in case of failure in the motor-generator connection. The switches in the direct tie and the motor-generator connection are interlocked so that only one can be closed at a time. Auxiliaries are so connected that they may be fed from either bus, the switches being provided with interlocks so that both cannot be closed at the same time. With the present auxiliary load the auxiliary bus fed from the main station bus is not necessary. The house turbine is ample to carry the entire load. When the second 60,000-kw. unit is installed, however, the auxiliary load will exceed

[1] Dwight P. Robinson & Co. Mem. Am.Soc.M.E.

the capacity of one house turbine, resulting in part of this load being placed directly on the auxiliary bus and being fed from the main bus. Only as much load will be thrown on the house turbine bus as is necessary for heat balance.

For starting purposes an 1100-volt bus is provided, which obviates the necessity for compensators and other starting devices. The starting and running switches are provided with sequence interlocks, which makes it impossible to close the switch on the 2300-volt bus until after the 1100-volt switch has been closed and opened.

Due to the slip in the motor-generator set, the frequency produced by the generator is about 57 cycles when the main bus frequency is 60 cycles. If the speed of the house turbine is varied so as to make its frequency slightly above or below that of the house-turbine bus, the amount of load carried by the house turbine will be correspondingly varied. The system of using a house turbine paralleled on the main bus is not new, but in existing installations of this kind considerable difficulty has been met with, due to differing characteristics of the small house turbine and the large units supplying the main bus. The motor-generator set mentioned above was introduced into the system to avoid this difficulty. This piece of apparatus acts somewhat like a flexible coupling, taking up the momentary variations in frequency on both sides. This arrangement permits of any desired variation in the quantity of exhaust steam available for heating the feed-water since the greater part of the steam for feed heating comes from the house turbine. Its control can be practically accomplished by manipulation of the house-turbine governor control on the main switchboard alone. Manipulation of the barometric injection valve is occasionally necessary. A graphic recorder in the control room indicates the boiler-feed temperature so that the switchboard operator can maintain the boiler-feed temperature at any desired point.

The general heat cycle is indicated on the diagram, Fig. 2. As will be seen from this diagram, the condensate passes from the hot well to the double-effect evaporator, where it acts as a circulating medium in the evaporator condenser, absorbing the heat of vaporization from the water evaporated. Thence it goes to a head tank located on the boiler-house roof. This tank merely acts as a small storage reservoir to take care of variations in water flow in this part of the system. Normally, the make-up to replace water losses throughout the system enters the flow at this point as well as returns from the main unit glands and other miscellaneous clean-water returns with the exception of the high- and low-pressure drips. The water from this tank flows to the barometric condenser whose steam supply originates as described below. A sufficient quantity of steam is admitted to this condenser, the quantity being controlled as described in the preceding paragraph, to raise the water temperature to that desired for boiler feed.

Fig. 3 shows the position of the head tank, the barometric condenser and the boiler-feed tank, as well as the relative position of all steam apparatus in the heat-balance system.

Boiler-feed pumps and forced-draft fans, which are steam-driven, exhaust into an auxiliary exhaust header from which the evaporator is supplied. It is seldom, if ever possible to make the quantity of low-pressure steam in this header exactly right for the evaporator demand. Consequently, there is a connection through a flow or back-pressure valve to the house-turbine exhaust pipe. This valve permits any steam in excess of that required by the evaporator to flow into the house-turbine exhaust pipe and thence to the barometric condenser. It is occasionally necessary to regulate the amount of water going to the barometric condenser, and this regulation is accomplished by means of a motor-operated valve controlled from the turbine-room floor. There is in conjunction with this valve a position indicator so that the operator on the turbine-room floor can tell just how far this valve is open.

The manipulation of this system is very simple and positive. For days at a time the temperature in the boiler-feed tank will not vary more than one or two degrees from 210 deg. fahr. This variation is, of course, due to fluctuations in the total station aux-

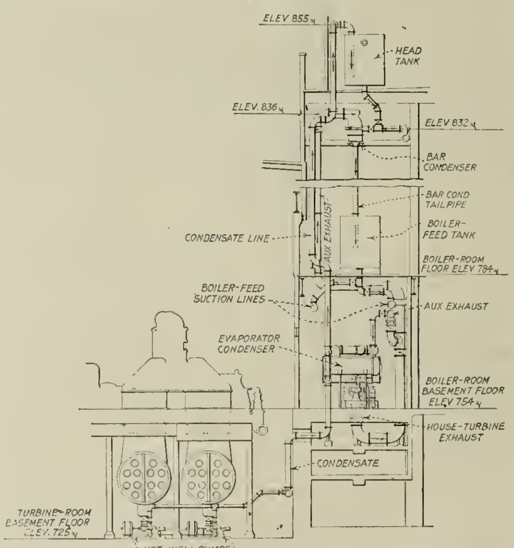

Fig. 3 General Arrangement of Feedwater System

T Industrial managers are studying operating conditions as never before in the history of business, and among the various phases of the subject which relate to the reduction of operating expense, the salvage of factory wastes comes in for a large measure of attention.

Let us first consider the question of salvaging metal wastes—for every factory in the country manufacturing a mechanical or semi-mechanical product produces metal scrap of one kind or another. It is essential that a system be set up whereby the various grades of metal chips and turnings will be kept separate in the shops during machine processes in order to save time and labor sorting and segregating in the scrap or salvage department. Non-ferrous metals should always be kept separate from steel and iron. When the parts machined consist of a non-ferrous metal with steel or iron, the chips should be run through magnetic separators.

In some of the bigger industries, chips and turnings are pressed into briquets of suitable cupola size, but this practice has not as yet become general throughout the country, and is carried on chiefly where the tonnage of chips and turnings is normally large. The process results not only in higher market value, but also in a material saving in transportation charges. Sheet-metal punching scrap, metal strips, trimmings, wire, etc., should always be put up in bundle form and in cupola size before being loaded for shipment, for the same reasons.

All the various classes of miscellaneous scrap metal, such as cuttings and trimmings from bar, rod, and heavy sheet stock, small castings, forgings, and solid pieces of every kind, should be accumulated in separate containers in the shop, for this class of scrap has a higher market rating than is obtained for chips and turnings.

Laboratory processes are often productive of valuable wastes either in the form of metals, such as tungsten, molybdenum, etc., or in the form of various chemical residues which may, through conversion or combination, become the basic elements of new preparations and compounds.

There is a wide variety of miscellaneous wastes which require our attention, and in this field a great amount of salvage work can be profitably done. Lumber, boxes, rope, rubber, fiber, cotton and woolen fabrics, cotton waste, paper, insulation materials, chemicals, etc., constitute some of the items which can be salvaged with profit in the modern industry. As an example, incoming boxes can be repaired and put in shape for future use either for storing materials, or as tote boxes in the shop. When too large to be suitable for these purposes, the lumber can be utilized for repairing and making tote boxes, temporary platforms, stagings, concrete forms, etc. The salvaging of lumber and making of boxes from this second-hand material in some of our large industries represents a saving of many thousands of dollars yearly in the purchase cost of new lumber. Even sawdust, usually considered of little value, can be used for the packing of porcelain and similar products, and the finer grades for the drying of metal parts in the dip shop. There is scarcely an item that we can name in the list of industrial wastes that has not some value either in its present state, or in the production of raw materials for the manufacturer's use. Even what is known as shop refuse may be burned in a destructor plant under boilers, and produce steam for heating and manufacturing.

A careful system of segregation is essential in the salvaging of metals, as well as of all other kinds of factory wastes, and this should be carried to the highest standard consistent with local conditions and without defeating the purpose of securing the highest market prices by undue expenditure for labor and equipment. It is well to have all scrap weighed and credited to departments for the twofold purpose of correct accounting and inculcating an interest for salvage work in all department heads.

But we must carry our salvage work into other branches of shop activity, such as maintenance of property, repairs to machinery and tools, handling of stocks, and upkeep of all the various classes of small tools, including lathe and planer tools, high-speed steels, etc.; and here is where the expenditures in big industries begin to mount up to vast sums, to hundreds of thousands and even to millions of dollars, during the course of a year. It is essential, therefore, that systems be set up whereby all these items of maintenance will receive the most careful scrutiny and the expenditures will be adequately limited and controlled. Systems must be set up governing the distribution and repairs of the various classes of small tools so that the consumption of these will be regulated within certain defined limits of economy and efficient service, in accordance with production requirements in the shop. It is good practice to make regular monthly inspections of machine tools and equipment, and make a record of the same, in order that repairs may be made promptly at a minimum of cost before the damage becomes more serious or breakdown ensues with increased repair expense and added delay to production. The record is valuable as showing the relative cost of maintenance and relative life of service of various makes of tools. It is often good economy to replace a tool showing high maintenance cost with a new tool of some other make, and thus save both expense and delays to production. In all cases of replacements and repairs, valuable parts should be salvaged and made use of on other jobs of repair work, wherever practicable.

In the supply of small tools to the shop much can be accomplished in the way of reducing expense by efficient methods of distribution and collection. A system of regular inspection of toolrooms, tool cupboards, benches, and areas around machine tools should be established in all departments. Tools not needed for immediate or current use should be cleared up promptly and returned to stock, and those needing repair put into shape for further requirements. This is particularly important in the case of high-speed-steel tools where the cost is relatively high by comparison, and a single idle tool may represent a good many dollars of tied-up capital. Nearly all the various small shop tools, such as wrenches, vises, hammers, drills, cutters, pliers, files, and numerous others can be repaired to good advantage and thus be made to give greatly lengthened service and reduce the number of purchases of new tools. By a properly organized system of distribution and collection the inventory of tool stocks carried may be greatly reduced, expenditures for new tools curtailed, and those in use in the shops kept more constantly in active service.

The subject of lubrication both of machine tools and of cutting tools affords opportunity for valuable reduction in the operating expense of the shop. With modern storage equipment and modern facilities for distribution to the shops, also proper feed pipes and oilers for regulating the supply to tools, a material saving in consumption of oils and cutting compounds can be made. Selection of oils is most important, and this should always be made with a view of reducing friction load on bearing surfaces and of keeping tools properly cooled and lubricated during the process of cutting, and not primarily in reference to cost. Valuable work has been done in recent years in the substitution of mineral oils and mineral lard oils for pure lard oil in a variety of processes where formerly pure lard oil was felt to be necessary. In fact, a heavy-body mineral oil of correct specifications will do the greater percentage of jobs commonly done with lard oil without any material increase in consumption, and with greatly reduced cost. A high-grade light-body mineral oil will also do many processes, such as turret-lathe work, milling high-carbon steels, etc. Soluble cutting compounds also have their place in machine-shop practice, and their use in a great variety of processes, such as drilling and milling, plain lathe work, cold cutting, etc., results in a greater economy than can be secured with oil. Attention needs to be given to the handling and distribution of oils in order to avoid waste. Machine tools should be equipped with proper tanks, drip pans, and aprons,

---

[1] General Superintendent, General Electric Company. Mem. Am.Soc.M.E.

For presentation at the Annual Meeting, New York, December 5 to 9, 1921, of The American Society of Mechanical Engineers. Copies of the paper may be obtained gratis upon application. All papers are subject to revision.

in order that nothing may be lost. Reclaiming oil from production parts and from chips and turnings is a part of the salvage work of every up-to-date factory and one that need not be enlarged upon here.

We hear much talk these days on the subject of reducing inventory, and it is essential that the work be carried forward intelligently and earnestly in order to put industry on its feet. The present is the time to make thorough investigation of every department and storage space, and to gather up all surplus or idle materials and made effort to put them into service, or otherwise dispose of them to advantage. Analysis must be made of the methods of handling and distributing materials in order to establish improved systems, reduce labor, and avoid delay or damage. Special attention should be given to cutting raw materials to required dimension or multiples of required dimension in order to save waste; and to the salvaging of all left-over pieces and parts for further use in some portion of the factory, wherever practicable. For this purpose the central storehouse should act as a clearing house, and thus render aid in the general work of salvaging.

The human element enters into salvage work, as into all other industrial operations. If we can get department heads, and employees as well, interested in saving everything of inherent value, we will perform a valuable service in helping to reëstablish industry on a firm and stable basis. Not only industrial managers, but the public as well, are more and more becoming interested in this most vital of human problems. One of our big industries salvages annually, in normal times, more than eighty million pounds of factory wastes. The railroads also have caught the spirit of thrift and are establishing new practices which are showing greatly improved conditions as regards operating expense. The country at large in a recent year saved scrap, consisting of several items—metals, paper, rags, wool waste, cotton fabrics, etc.—aggregating more than one and a half billions of dollars.

In the years immediately before us, industry will be called upon to bear a large portion of the burden in the vast and arduous work of reconstruction. As engineers and managers we need, therefore, to be strongly imbued with the vital principles of economy and thrift, and with the importance of greatly increased effort along the lines of salvage work. The question of profit must not always be a deciding factor, but we must conduct our operations with a broader view of saving everything which may be of value to others in the production of raw materials or finished fabrics, whether we gain immediate, direct profit or not. The manufacture and supply of raw materials depends so often upon the supply of various kinds of scrap and waste that it is most essential we give consideration to the country's needs as a whole and do not limit our efforts at salvage work to our own desire for immediate profit. Indirectly we shall receive benefit through reduced cost of the raw stocks we purchase for our own manufacturing purposes because of the abundance of original materials which we have helped to create.

No appeal to the manufacturer to save the waste products of industry can be made too forcible or too strong, nor can we lay too much emphasis upon the necessity for every individual joining earnestly with us in this great work of universal benefit to the country at large. Every pound of junk saved at our homes and turned over to the junk dealer in the end reaches the great melting pot, and finally the marts of trade, in the form of raw materials to be of definite value to some one; and that one, incidentally, may be any one of us here engaged in the profitable manufacture of fabrics which serve a public need. The nations of Europe, through the very exigencies of the war, were forced to carry on the work of salvaging to its greatest limit in order to sustain the people at home and the armies in the field; and now, during the period of reconstruction, they appear to have doubled their effort and to have gone beyond this limit in the struggle to rebuild government and business and industry on a stable and enduring basis. We in America are gradually becoming more and more aroused to this big problem in our public and private life. We have been given to waste and extravagance in the past, but we are gradually awakening to the fact that it is not so important what we have or what we produce as what we are able to save and reclaim from all the various processes of production. What we need to learn as a nation and as individuals is the vital importance of practicing the simple precepts of economy and thrift and of guiding all our actions both in business and private life to that essential end. We need to learn to save everything of inherent value, and in doing this we ourselves shall derive a benefit in the general public good.

We ought to have a permanent reclamation service, fostered and maintained by our National Government as other public services are fostered and maintained. Through this office practical appeal could be made to the governors of states, through the governors of states to mayors of cities and presidents of villages, and through these latter to the heads of boards of trade and to public-spirited citizens, to coöperate in the great work of saving the nation's wastes. Through this channel also could be disseminated much useful knowledge and instruction relating to the work of reclamation, which would thus reach in a helpful way not only the populous industrial centers but the outlying districts as well, and by this means bring about a widespread, concerted action for the public good. No one may attempt to predict the full extent of the value or the aggregate return of such a movement to the Government and country at large.

Still another phase of salvage work which is distinct and apart from the field of salvaging metal scrap and other factory wastes, is the saving of time and of human effort, the harboring of mental and physical energy, and the devoting of all our effort to the highest purposes and the highest aims. Profitable manufacturing requires that we build up our organizations both in offices and in the factory with a view of concentrating directive effort, eliminating duplication of orders and instructions, establishing unity of purpose, system in method of procedure, and coöperative effort on the part of all employees, whether serving in official capacities or in the lower grades of mechanical and physical labor. It is essential that we organize departmental forces in such manner as will secure systematic control of all the functions of labor and consumption of materials, and the keeping of manufacturing expenses within the budget provided for conducting shop and office work. We must build our organizations with a view of attaining the highest standards possible, in order to reëstablish business on the high plane of influence which it must always occupy in the successful upbuilding and support of our Government and nation, and in the permanent establishment of the normal pursuits of industry and peace.

ON THE ART OF MILLING

(Continued from page 789)

10 deg. and probably is up to 15 deg. This statement is made definitely for steel up to 0.50 carbon, and it is believed that it will be found true for all metals.

Experiments With Machineability Tester

The Machineability Tester was designed, as stated earlier, for measuring quickly the machineability of different metals. This machine is shown in Fig. 16. If the weight be allowed to fall freely from the top position, it will rise almost to the same height. A pointer indicates the highest position to which the weight rises and this is taken as the zero reading. If, in a subsequent fall, a chip be formed then the weight will not rise as high. This change in height is a measure of the energy given up in forming the chip. The same principle is used in impact-testing machines.

One group of experiments run on this machine are recorded, as they were carried out to emphasize the analysis brought out previously that maximum chip thickness is the sole criterion of efficiency for a given tool and material. Four different depths of cut and four different feeds were taken, giving sixteen differently shaped chips in all.

The results of these sixteen experiments are given in Fig. 17, in which cubic inches per horsepower-minute are plotted against maximum chip thickness. It is seen that efficiency is a function of maximum chip thickness alone.

The importance of the above point of view cannot well be overemphasized. In arranging instructions for the operation of milling machines, in compiling feed and depth-of-cut data, or in comparing different jobs, the fact should be kept in mind that maximum chip thickness is the true criterion of cutter-tooth punishment.

Avoidable Waste in Car Operation —The Container Car

By WALTER C. SANDERS,[1] NEW YORK, N. Y.

This paper describes the "container" cars which have recently been placed in service on the New York Central Lines and others having improvements on the original type which are now under construction.

The advantages claimed for the container car are that less-than-carload lots of freight, mail and express may be shipped with a material saving of time to the shipper and the railroad company, in that the container car may be rapidly unloaded and reloaded. The car will also permit the railroad to secure the maximum mileage out of rolling stock.

Valuable commodities of all kinds can be transported from consignor to consignee inviolate from damage by fire, weather, breakage or theft, also eliminating to a great extent rehandling, trucking and checking.

THE container car was an outcome of the railroad congestion during the war and was first put into operation last year by Mr. A. H. Smith, president of the New York Central Lines, to reduce the transportation losses due to congestion which tied up industry. This congestion was caused by the railroads being unable to get rolling stock near the platforms or places where cars could be unloaded and reloaded and put back into circulation. In some cases manufacturing plants used box cars as a storage warehouse, gladly paying the demurrage charged by the railroads. It is hoped that mail, express and freight robberies, breakage, checking and rehandling, delays to shippers, and many other railroad evils may also be materially reduced by the container-car system.

Fig. 1 The Express-Type Container Car with the Containers Removed

At the sides are visible the guides which hold the containers firmly.

Loss of and damage to freight has grown in recent years into one of the heaviest leaks in the transportation industry and strenuous campaigns which included maintenance of extensive police and supervisory forces, together with educational campaigns among shippers and railroad employees to secure stronger packing, careful handling and suppression of theft, have failed to stop this economic waste.

The proportions of this transportation problem may be judged from the fact that in the year 1914 American railroads paid out $33,000,000 in claims for loss of and damage to freight, and for the year 1920 this mounted to a total of $125,000,000, the incidental injury to business affected being considerably greater. Under the ordinary system of handling less-than-carload lots or shipments the goods are checked and handled item by item from shipper to truck or dray, from truck to depot platform or warehouse, and from the platform to the car. They are subject to handling and checking at each stage of the journey, and when finally they reach their destination this handling and checking is all done over again. It is therefore necessary to maintain armies of employees to act as freight handlers, clerks, checkers and station overseers, as well as switchmen to shunt cars to fixed locations where loading and unloading are possible.

The container system provides that the portable container shall be loaded and locked at the shipper's own store door, conveyed by motor truck to the railroad yard, and lifted by crane aboard the container car, where steel bulkheads and sides form absolute protection against opening the container in transit. At the destination the locked container is unloaded by a crane and carried by motor truck directly to the warehouse or consignee's door, to be unloaded at his convenience. This simple system of handling goods will make it possible to greatly reduce the force of employees now necessary.

Fig. 2 The Express-Type Container with the Containers in Place

The steel sides of the car prevent the doors of the containers from being opened.

Another advantage of the container-car system expected to prove most valuable is the greatly increased use of container rolling stock in moving service, which is particularly important when traffic expands to its "peak" and the prime need is to shorten layovers of cars in yards and stations for loading and unloading, and to limit their idleness and obstruction through misuse for storage purposes. In busy times the need is to keep every wheel

turning as continuously as possible to secure maximum transportation. With ample supplies of the removable containers, which in their several classes are of uniform size and interchangeable, one carload of containers may be removed and sent with their

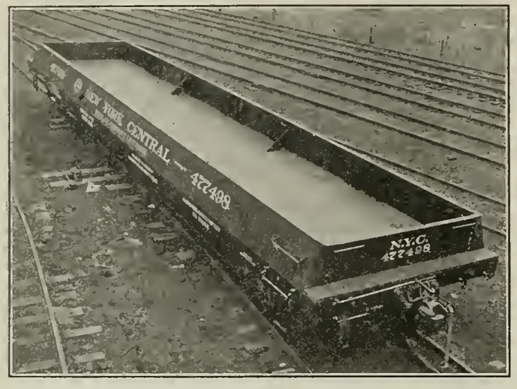

Fig. 4 The Freight-Type Container Car With the Containers Removed

Since this photograph was taken cross-plates have been added to keep doors of containers from being opened after one or more containers have been removed from the car.

loads to consignees, and another set immediately hoisted into place and the car be ready to proceed within a matter of minutes in most instances. The locked containers may remain on station platforms or at the stores of shippers for loading or unloading at convenience

Fig. 5 The Freight-Type Container Car With Containers in Place

It will be noted that the car differs materially in appearance from the express type. This photograph shows two large and two small containers. The large containers have been cut in two, making the standard equipment for this type of car 6 containers.

without tying up costly rolling stock at points where track capacity is limited and congestion quickly obstructs the flow of traffic unless the cars are kept moving. With this rapid handling of the containers on and off the car the mileage per year made by the ordinary piece of rolling stock may be doubled, and it is predicted that the tremendous expense of maintaining box cars and other rolling stock equal to all emergencies will be materially cut down.

The container car may make costly packing and crating unnecessary because goods packed in flimsy pasteboard boxes or even bound with heavy paper are protected against breakage, theft, and water or weather damage.

There are at present in service on the New York Central Lines, three container cars, one of the mail or express type, and two that are being used for valuable freight, such as silks and woolens. Three new mail cars of improved design which are now being constructed will be equipped with an improved type of all-steel container. A new freight-type container car is being designed, and refrigerator and tank container cars are contemplated.

General Description of the Container Car

The container car is nothing more than a long car with a steel side or fence, similar to a low-side gondola, loaded with large steel safes or containers, made as light as possible, in which commodities of all kinds travel from consignor to consignee, inviolate against thieves, fire, weather and breakage. The safes or containers are lifted on and off the car by cranes or hoisting devices, permitting

Fig. 6 Unloading a Container From the Freight Type of Container Car

the "parent" rolling stock to continue in immediate transportation circulation. In appearance the loaded car seems to be a solid load of safes or steel vaults set aboard a steel underframe with a low protecting steel fence.

Fig. 7 A Freight-Type Container Leaving the Railroad Yards on a Motor Truck

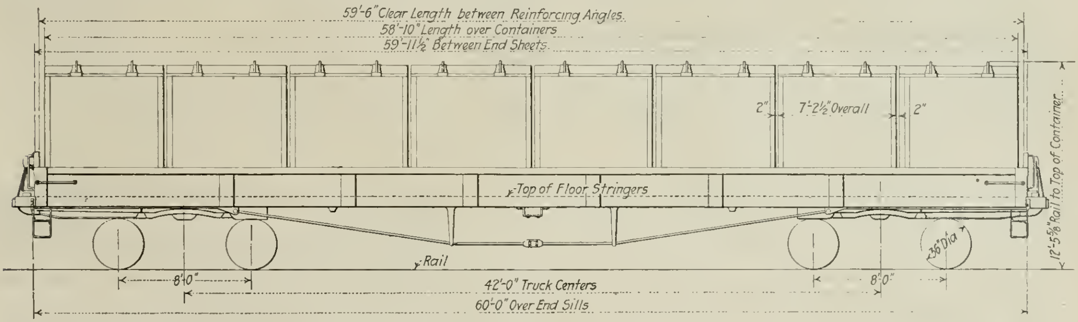
Express Container Cars

The present express car now in use is 61 ft. 3 in. in length, with trucks and fittings that make it interchangeable with standard passenger equipment for use in any passenger train. All modern safety appliances for a special type of car are installed, such as air brakes, hand-hold irons, sill steps, etc. This car carries nine containers, each 9 ft. wide by 6 ft. long, with an inside clear height of 7 ft. 4 in. and a door 3 ft. by 6 ft. The containers are as nearly

and are arranged with four eyelets or hooks, one at each top outside corner, for convenient lifting and handling. The doors are of standard refrigerator design and are arranged with a hasp and staple for the shipper's padlock, also with pin and slot for standard freight-car seal.

The steel sides of the car are spaced to suit the width of the containers, with a clearance of $^1/_2$ in. on each side; the containers cannot be made as wide as the car itself because of the various state highway laws which regulate the width of motor trucks. The New York State law, for instance, limits the width of an auto truck, including body, to 8 ft., the height from road to top of truck or lading to 12 ft. 6 in., and the truck and lading must not have a combined weight of over 25,000 lb. All container cars are fitted with bulkheads and steel sides 2 ft. high into which the containers fit.

In the interior of the body of the gondola part of the car are sectional guides, made of $^1/_4$-in. steel, resembling channel steel, with the laps projecting out from the open ends to enable them to be riveted to the sides of the car. There are guides at each place



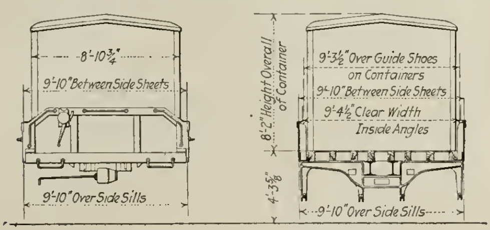


Fig. 8 General Arrangement of Improved Type of Mail Container Car Now Under Construction
This car carries 8 containers.

on the side of the car where the corner of a container will lie.

At each corner on the length side of each container there is a shoe, also of pressed steel, which will fit into the socket formed by the two guides. This arrangement guides the containers to the floor of the car and holds them in place while the car is in transit, without additional blocking or fastening. If it is found necessary to move the car over the road after one or more containers have been removed, it is unnecessary to put in any kind of blocking, because these guides and shoes are arranged to hold the containers and prevent them from shifting or falling over due to the oscillation of the car.

Freight Container Cars

The two freight-type container cars are 50 ft. long. This is exceptionally long for a car used in freight service, being 9 ft. longer than the longest of New York Central box cars. The general construction is similar to that of the express-type container car.

The freight type carries 6 containers, length 6 ft. 7 in., width 7 ft. $1^1/_2$ in. and clear height 7 ft. 7 $^3/_8$ in., all inside measurements.

Each container has a steel frame, base, and roof of open-hearth steel, sides or walls of fir wood, and a radial roof so that water will shed off. All joints are double-riveted. The door in the freight type of container is located in the width side and is of standard refrigerator design. As the door is in the end or width through the open clearance spaces between containers, so in case one or more containers are removed from the car, the doors of the remaining containers cannot be opened.

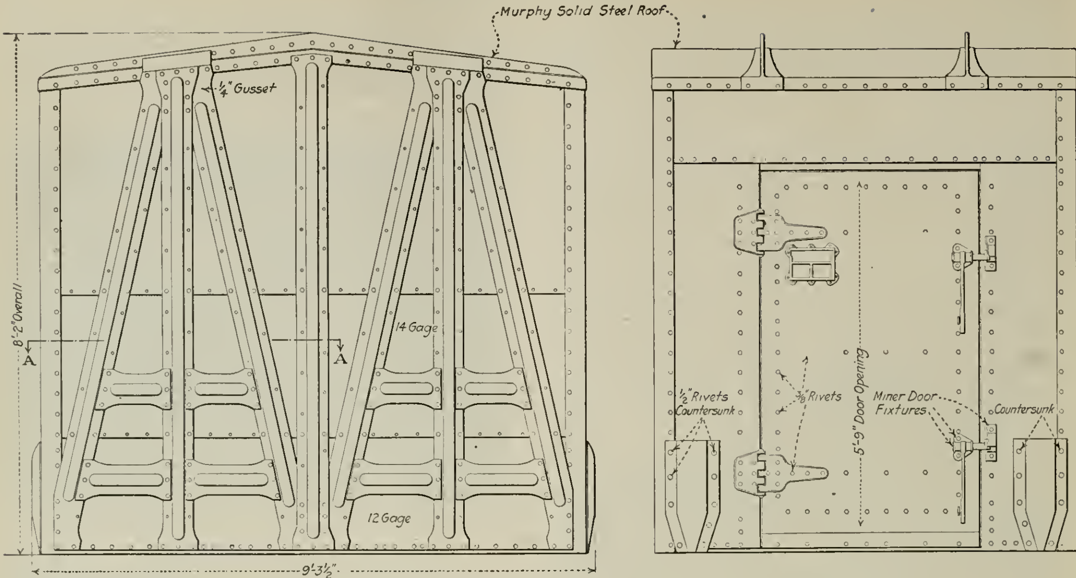
Containers and Container Cars Now Under Construction

The three new mail-type container cars now being built will carry 8 containers of a new, improved design, the outside measurements being, length 7 ft. $2^1/_2$ in., width 9 ft. $3^1/_2$ in., clear height 8 ft. 2 in., with a 5 ft. 9-in. by 3 ft. 6-in. door on the length side of the container. The cubic capacity will be 438 ft., light weight 3000 lb. and capacity 7000 lb.

Tests conducted in the last few months on the New York Central Lines have demonstrated that the express type of container car can be emptied of the nine containers by an ordinary crane in 21 min. and reloaded with other containers and the car put back in circulation in about the same time. This test was made with an ordinary moving track crane, since no special cranes or handling devices have as yet been constructed for use in handling the containers. With the special handling devices contemplated it will be possible to unload the containers with greater speed directly to waiting motor trucks, platforms, or on the ground.

During May, 1921, at the request of the Postmaster General, a mail test was run from New York City to Chicago, Ill., and return with the express type of container car. Upon arrival at Chicago the nine containers, containing 37,000 lb. of mail, were unloaded onto waiting Post Office motor trucks in 21 min., which is one-fifth of the time used in unloading an ordinary mail storage car. At Chicago connections were made with western mail trains that have never been made before. Upon the arrival of the car at New York on the return trip the containers were removed from the car in 18 min.

It is believed that the use of containers in mail service (1) will prevent the loss in transit of valuable registered mail, parcels post and other mail; (2) will mean a saving to the Government in handling mail, both in trucking and checking, as well as a material saving to the railroads in the use of equipment; (3) will make possible a quick transfer at important gateway points and the maintaining of close railway connections otherwise impossible; and (4) will afford an increased weight and capacity as compared with the average load now handled in mail storage or baggage cars, the average weight of mail now carried in mail storage cars being approximately 30,000 lb.; 37,000 lb. of mail were carried on the run to Chicago.



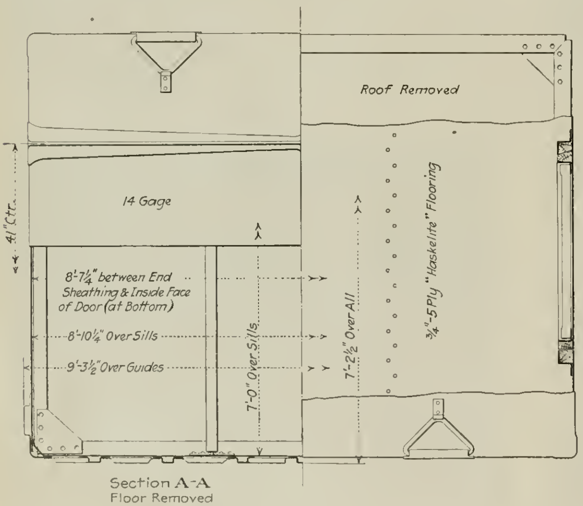


Fig. 9 General Arrangement of the New Improved Type of Mail Container

Note the eyelets for lifting and handling at the top.

Summary

A summary of the prime advantages of the container-car system is as follows:

(*a*) It will furnish a means of expediting delivery of less-than-carload lots of commodities by eliminating the time and expense of rehandling, checking and trucking

(*b*) It will eliminate costly crating and packing

(*c*) The immediate unloading and loading of containers at terminal points eliminates the item of demurrage, at the same time promptly releasing rolling stock, clearing the yards of cars and reducing congestion

(*d*) It will eliminate the piecemeal loading of cars at railway sidings in exposure to all kinds of weather

(*e*) It will tend to keep the car moving at all times, making possible double the mileage as made now by an ordinary piece of rolling stock

(*f*) Containers are fire- and weather-proof, and also burglar-proof in that they cannot be opened while on the car or while being transferred by handling device to and from the car.

The increased service capacity of each unit by the development of the container-car system is thought to hold far-reaching economic possibilities in railroad operation of the future, as well as in the coördinated use of the motor truck and the electric railway.

Advantage of Nitrogen in the Boiler Furnace

Recent developments seem to indicate that open-hearth steel furnaces will soon be using oxygen in place of air for combustion. This would undoubtedly shorten the melting period and give more economical operation.

In the boiler plant, although the same union of oxygen with the combustible in the fuel takes place, it would be very undesirable to introduce oxygen unmixed with the inert nitrogen. A pound of pure carbon in burning unites with 2.67 lb. of oxygen to give 3.67 lb. of gases and a total of 14,600 British thermal units is released. The heat contained in each pound of gas products would be approximately 4,000 B.t.u. If the specific heat of carbon dioxide is taken as 0.2, the temperature resulting from the combustion with no loss would be over 20,000 deg. fahr. This temperature is far above the melting point of either furnace walls or boiler plate. While this high temperature would increase the rate of heat absorption of the boiler, the temperature of the chimney gases would be high, since the small volume of highly heated gases would not be able to throw off as much heat as is possible with a larger volume of gases.

With air entering the furnace, instead of only 2.67 lb. of oxygen combining with the carbon we have 8.87 lb. of nitrogen carried along with the oxygen. The total weight of the gases then becomes 11.54 lb. and the theoretical flame temperature is reduced to around 5,000 deg. The weight of the nitrogen mixed with the oxygen reduces the heat generated per pound of gases, thereby reducing the furnace temperature. The larger volume of temperature gases transmits the heat more efficiently to the boiler. The presence of the inert nitrogen is actually an advantage.—*Power*, Oct. 25, 1921, p. 647.

Material Handling an Important Factor in the Elimination of Industrial Waste

By H. V. Coes,[1] Philadelphia, Pa.

It is only recently that industrial plants have been designed or laid out on a material-handling basis, and the present paper is timely in that it points out the opportunities in almost every branch of industry to reduce large wastes in material handling.

The problem of reducing the waste in material handling is not always an easy one and initial solutions are frequently complicated. However, thorough analysis will generally reveal a simple solution.

One authority postulates the principles: First, in handling material, perform only the handling operations that are absolutely essential; second, perform these operations in the way that secures the lowest cost.

Too much thought cannot be given to the selection of equipment that not only shows a saving, but fits into the general operating conditions of the plant, or suits physical conditions imposed by plant or location, and yet at the same time fits into plans for the future extension, development or rehabilitation of the plant.

The Committee on Elimination of Waste in Industry of the Federated American Engineering Societies states, "It is peculiarly the duty of engineers to use their influence individually and collectively to eliminate waste in industry."

The Materials Handling Division of our Society is concerned with the wastes of (1) capital, (2) material, (3) labor, and (4) production, resulting from lack of or inadequateness of material-handling equipment and methods in industry and their inefficient use and operation.

Modern civilization is the direct result of the application of the principles of subdivision of labor. This in turn has resulted in inventions largely labor-saving, and material-handling devices have played an important part in this development. Yet today, in spite of equipment and methods now available, material is handled constantly in identically the same manner as in the early stages of civilization.

Why is this? In the opinion of the author it is due to a number of influences, such as

1. Ignorance of methods and equipment available
2. Lack of standardization of materials, methods, containers to be handled to permit installation of and economical use of material-handling apparatus
3. Insufficient comparative economic data
4. Improper engineering
5. Poor salesmanship and selling policies
6. Lack of a central organization to educate the public and to act as a clearing house for economic and technica information.

There has recently been published an Encyclopedia of Material Handling, prepared by recognized authorities. This is a step in the right direction and it should prove of considerable assistance, particularly in eliminating ignorance of methods and equipment. The meetings and symposiums of the Materials Handling Division of our Society will, if conducted and prepared along broad lines, aid largely in the educational campaign.

Lack of standardization of containers is a peculiarly potent deterrent to proper economic solutions of material-handling problems, particularly at express and package-freight stations, terminals, transfer points and steamship docks. The. Materials Handling Division can perform a service of inestimable value to the country by forming strong committees to make an engineering study of this important problem. A proper solution would reduce waste due to loss and breakage, waste of transportation space, waste in production, and shipping costs.

It is a well-recognized fact in industrial-plant operation that the last 20 per cent of operating efficiency is the hardest to obtain, and yet shows the highest return. Thousands of plants in this country do not show an operating efficiency of more than 50 per cent, as compared with those plants that have an operating ratio as high as the present state of the art will permit. There are many reasons for this low operating ratio, but we are concerned only with the losses due to inadequate and inefficient material handling.

Industrial costs are composed of the following factors:

1. Material
2. Production labor
3. Factory burden or overhead
4. General administration expense
5. Sales expense.

As a usual thing, indirect or non-productive labor is charged out to factory burden. A very large portion of this labor is used in picking up, putting down and transporting material of all kinds. Hence one place to start in reducing factory burden is to reduce waste in labor and expense in this indirect-labor item by substituting adequate and properly adapted material-handling equipment and methods.

A Few Examples of Savings Effected

Some specific cases will help to visualize the situation better.

a In a large plant in Cleveland, Ohio, 55 men and 25 units are doing the work which today would require 550 men for handling alone, if they reverted to the old methods of five or six years ago.

b A tractor and 16 trailers reduced the yard gang from 18 to 4 men and eliminated a mile of industrial track, the salvage of which nearly paid for the initial installation.

c Mr. Max Sklovsky,[1] after an exhaustive study of material handling in his foundry, recently made the startling statement that he was handling 168 tons of material for every ton of finished castings produced, the figures for 100 tons of castings being as follows:

	Tons
Metals	2,606
Coke and lime	95
Core material	1,278
Molding sand	7,491
Equipment	5,150
Miscellaneous	200
Total	16,820

d Mr. W. G. Bridgeman[2] cites some interesting comparisons of handling costs at terminals. Two-wheeled trucks were used under the old method, electric tractors in the new method.

Terminal	Tons per man per hr., old method	Tons per man per hr., new method	Cost difference per ton
Wilmington, N. C.	0.873	3.49	$0.281
South Atlantic port	1.29	2.72	....
Cincinnati	0.722	0.918	0.14
St. Louis	1.2	1.8	....

Mr. Bridgeman further states that in his opinion 75 per cent of the freight houses in the country can increase production per man per hour anywhere from 25 to 100 per cent, and this will be accomplished mainly by the use of mechanical equipment for handling freight.

e Mr. J. A. Kreis,[3] states that their 20-ton locomotive crane "not only speeds up handling of material but pays for itself every $4\frac{1}{2}$ months."

f A battery of 4 Wellman-Seaver-Morgan unloaders can now unload a 10,000-ton ore vessel in $3\frac{1}{2}$ hrs. In the old days, using a clamshell bucket, the cost was around 25 cents per ton; today it is $2\frac{1}{2}$ to 4 cents per ton. This cost includes overhead, interest on plant investment, and maintenance.

g Table 1 is an example of the rehabilitation of a paper mill by material-handling methods. The mill was 60 years old or more, and had grown around itself in a manner that presented a number of problems difficult to solve. After a policy for rehabilitation and extension had been worked out, it was possible to predict future material-handling costs, based upon improvements that would obtain under the rehabilitation plan and application of the proper material-handling equipment to the problems in hand. The table illustrates the varied material to be handled, but one would need to know the physical handicaps at the mill to fully appreciate the necessity for and the difficulty of obtaining a right solution of the problem. The preliminary testing out and checking up of the equipment as installed indicates that the savings will be readily obtained and in some cases exceeded as operating proficiency increases.

It can thus be seen that there are opportunities in almost every branch of industry to reduce large wastes in material handling.

The Art is New and Requires an Unbiased Viewpoint

The public, industrial executives and business men generally are not in possession of sufficient data and economic facts to make them realize the astounding wastes going on all around. Engineers and manufacturers are largely to blame for this. The industrial executive usually knows how much per piece or per unit it costs to produce a given article, but rarely knows what it costs per unit to handle the materials entering into the manufacture of the article itself or the cost of handling the finished article. It is only recently that industrial plants have been designed or laid out on a material-handling basis. The writer knows of plants that do very well in normal times whose physical handicaps due to the absence of any consideration of material handling in the old days are such that it is a physical and financial impossibility to provide adequate material-handling methods and equipment for them. In many cases like these the savings in labor alone would pay a very substantial part of the fixed charges of a rehabilitated or a new plant.

For instance, a certain modern plant cost, including land, $1,500-000. It is operating today at about one-third capacity, yet the savings in labor alone pay the annual fixed charges of $145,000.

In many instances manufacturers of material-handling equipment have been remiss and short-sighted in selecting men of the wrong type to represent them, men in many instances without knowledge or comprehension of the underlying economic laws. Capital wastes, dissatisfaction, and frequently bitterness result from sale of unsuitable, inadequate or incomplete equipment.

If the manufacturer will get the engineer's point of view and the engineer the manufacturer's, and both will get the economic viewpoint, much good will result, fewer mistakes be made, and society and industry will benefit and prosper. By all means, then, let us work for right solutions of our material-handling problems. Let us be fair to each other, to ourselves, to the public, to labor, and make one dollar, not ten dollars, do the work of one. A proper attitude of mind in material-handling problems is important.

Initial Solution Not Always Best, But Perseverance Wins

The human mind apparently functions in a peculiar manner, particularly in connection with mechanical or technical problems. It seems necessary to start with the complex before the simple can be attained. This characteristic of the mind needs to be watched very closely in its relation to material-handling problems. The problems as usually presented in almost any industrial plant or terminal tend to confuse. The tendency of the mind to see the problem in all its complexities frequently leads to a complicated initial solution, but as a rule these initial solutions are rejected as the simple, less costly and more efficient solution finally evolves. We should analyze the problem, carefully determine the number of transfers and make ourselves find and retain the simple solution. Therefore, we should not be discouraged if the first solution does not yield the estimated savings that it is felt should be secured, but should persevere until a thorough analysis reveals the simple solution.

It should be the endeavor of our Materials Handling Division to place material-handling matters on a high plane; to seek the truth relentlessly and fearlessly; to secure a thorough exchange of views; to obtain a better understanding by the public, by labor, by engineers, by the manufacturer, of the real economic purpose of material handling.

Lowest Cost the Goal in Handling Materials

The initial test of any method, system or device, should be an economic one. The question of will it pay should not be begged. Capital has been wasted, pioneers discouraged, the public bewildered because of undertakings not conforming to this test.

Mr. Wm. F. Hunt[1] postulates these principles as follows:

1 In handling material, perform only the handling operations that are absolutely necessary

2 Perform these operations in the way that secures the lowest cost.

When a simple plan for handling materials has been developed, the financial returns of the installation will, in the absence of labor difficulties, largely determine the wisdom of the installation. It may pay to install apparatus and it may not, according to conditions such as:

a Constancy or intermittency of the work

b Character of the operation itself

c Results of analysis which follows.

TABLE 1 ESTIMATED ANNUAL COST OF PRESENT AND PROPOSED MATERIAL HANDLING
(Based on Average Quantities Consumed in Year 1919 and 6 Months 1920)

			Present Cost[1]			Proposed Cost[1]		Annual Saving		
Material	Unit	Average Annual Consumption	Unit	Total	Estimated New Investment	Unit	Total	Unit	Total	Equipment Selected
Alum	Ton	207	$10.60	$ 2,862	$ 5,500	$1.87	$ 505	$8.73	$ 2,357	Locomotive crane and power mule
Ash disposal	Ton	4,800	2.08	10,000	15,000	0.42	2,000	1.86	8,000	Pneumatic conveyor
Bleach	Ton	875	2.80	2,450	......	2.00	1,750	0.80	700	Locomotive crane and power mule

Lumber: Strips	M.B.M.	100	6.00	600	......	3.50	350	2.50	250	Loco. crane and gravity conveyor
Pulp wood	Cord	10,000	4.10	41,000	60,000	1.67	16,700	2.43	24,300	Loco. crane and pneumatic conveyor
Rosin	Ton	250	6.55	1,637	6,000	1.00	250	5.55	1,387	Locomotive crane and power mule
Soda ash	Ton	545	2.40	1,310	500	0.50	273	1.90	1,037	Pneumatic conveyor
Sulphite pulp	Ton	5,500	4.10	23,000	14,000	1.95	10,500	2.15	12,500	Power mule
				$99,773	$114,450		$38,708		$61,065	

[1]The present costs include maintenance and repairs but no fixed charges, or other overhead items. The proposed costs include fixed charges of 20 per cent.

If labor can be saved or manufacturing conditions improved by the use of apparatus for handling material, we can readily determine how much labor will be required by the method proposed. By comparing this method with the present method, we can ascertain the probable labor saving effected.

The investment justifiable to effect the saving is the item in the investigation that is the most difficult to analyze, as it has so many variables. The figures obtained by the following method are an indication of facts and the ultimate decision must be dictated by good judgment and a general consideration of the whole situation.

How to Arrive at the Best Method

The variables are many in the work to be performed. The work may be of temporary character, infrequently done, the amount fluctuating widely, or it may be a regular daily operation, year in and year out; this item varies from 0 to 100 per cent. If the work is of a temporary nature, no saving can be made, whereas if it is of daily necessity for the future, the whole saving of reduced labor by the plan suggested is available. The true value exists somewhere between these two extremes, and it need not be difficult to

Code on Definitions and Values

Preliminary Draft of the Fourth in the Series of Nineteen Codes in Preparation by the A.S.M.E. Committee on Power Test Codes

IN 1918 the Power Test Committee of the A.S.M.E. was reorganized to revise and enlarge the Power Test Codes of the Society, published in 1915. The Committee is a large one, consisting of a Main Committee of 25 under the chairmanship of Fred R. Low, and 19 Individual Committees of specialists who are drafting codes for the different classes of apparatus comprised in power-plant equipment. Below is reproduced the fourth of these codes to be completed, namely, Code on Definitions and Values.

The Individual Committee which developed this Code is headed by Mr. Reginald J. S. Pigott as chairman, and consists of the following men: Prof. Lionel S. Marks, Dr. Samuel W. Stratton, Albert C. Wood, Edgar Buckingham and Fred R. Low. This Committee will welcome suggestions for corrections or additions to this draft of its Code. These should be addressed to the Chairman, care of The American Society of Mechanical Engineers.

Code on Definitions and Values

The units to be employed in reporting the results of tests made in accordance with the various Power Test Codes are enumerated in Tables 1, 2 and 3. Explanatory and other notes follow in Pars. 60 to 112, to which references are given in the tables.

TABLE 1 FUNDAMENTAL UNITS AND CONSTANTS

Units	Abbreviations and Symbols	Definitions or Equivalent Values	Approximate Values Acceptable for Computation
1 One foot	ft.	12/39.37 of the length of the international prototype meter. (Par. 103)	
2 One pound mass	lb.	0.4535924 times the mass of the international prototype kilogram. (Par. 103)	
3 Standard gravity	g	32.174 ft./sec.^{2} (Par. 105)	
4 One pound force	lb.	A force represented by the weight of one pound mass at a place where gravity has the standard value. (Par. 105)	
5 One foot-pound	ft-lb.	The work done by 1 lb. force when its point of application moves one foot in the direction of the force.	
6 One British thermal unit	B.t.u.	1/180 of the heat required to raise 1 lb. mass of water from the ice point to the steam point. (Par. 109)	
7 Absolute temperature	T	deg. fahr. + 459.6 (Par. 108)	deg. fahr. + 460
8 Mechanical equivalent of heat	J	778 ft-lb. per B.t.u. (equiv.) (Par. 106)	778
Heat equivalent of work	A	0.001285 B.t.u. per ft-lb. (equiv.) (Par. 106)	0.001285
9 One horsepower	hp.	550 ft-lb. per sec. (def.)	550
		33,000 ft-lb. per min. (def.)	33,000
		1,980,000 ft-lb. per hr. (def.)	1,980,000
		2,545 B.t.u. per hr. (equiv.)	2,545
		745.702 watts (equiv.)	746
		0.7457 kw. (equiv.) (Par. 107)	0.746
10 One horsepower-hour	hp-hr.	2,545 B.t.u. (equiv.) (Par. 107)	2,545
11 One kilowatt	kw.	1,000 watts (def.)	1,000
		1.3410 hp. (equiv.)	1.341
		3,413 B.t.u. per hr. (equiv.)	3,413
		737.56 ft-lb. per sec. (equiv.). (Par. 107)	738
12 One kilowatt-hour	kw-hr.	1.3410 hp-hr. (equiv.)	1.341
		3,413 B.t.u. (equiv.) (Par. 107)	3,413
13 One U. S. gallon	gal.	231 cu. in. (def.)	231
14 One Standard atmosphere (International Standard)	atmos.	760 mm. mercury at ice point and standard gravity. (Pars. 108, 109 and 112) (def.)	760
		29.9212 in. mercury at ice point and standard gravity (equiv.)	29.92
		14.6963 lb. per sq. in. (equiv.). (Par. 112)	14.7
15 One ton refrigeration	ton refr.	288,000 B.t.u. (def.). (Par. 129)	288,000

It will be noted that the approximate values in the fourth column of Table 1 will not exactly cross-check with each other; if a check is necessary, for any reason, use the more nearly exact values in the third column.

Definitions and values which are of interest to special codes only, are to be found in the "Notes on Data" (Pars. 101–157).

TABLE 2 UNITS OF CAPACITY

Apparatus	Units
16 Steam Boilers and Superheaters	(*a*) Heat output in steam per hour. (Pars. 113, 130)
	(*b*) Actual evaporation, lb. of steam per hour, at stated steam pressure and quality or temperature, and stated feedwater temperature
	(*c*) Units of evaporation per hour = Item 19*a*/1000. (Par. 113)
17 Reciprocating Steam Engines	(*a*) Indicated horsepower at stated conditions of steam supply and exhaust
	(*b*) Brake horsepower at stated conditions of steam supply and exhaust
18 Steam-Engine Generators	Net kilowatts at generator terminals at stated conditions of steam supply and exhaust. (Par. 114)
19 Steam Turbines	Brake horsepower at stated conditions of steam supply and exhaust
20 Turbo-Generators	Net kilowatts at stated conditions of steam supply and exhaust. (Par. 114)
21 Pumping Machinery	(*a*) Gallons discharged in 24 hours at stated total suction and discharge pressures
	(*b*) Gallons per minute at stated total suction and discharge pressures
	(*c*) Water-horsepower output at stated total suction and discharge pressures. (Par. 119)
22 Compressors and Blowers, Centrifugal and Displacement	(*a*) Cubic feet of free air (or other, gas) per minute, at stated total intake pressure and temperature delivered at stated total discharge pressure
Low-Pressure Centrifugal only (less than 20 in. water total pressure rise)	(*b*) Cubic feet of free air (or other gas) per minute, at 68 deg. fahr. and one standard atmosphere or at 0.075 lb. per cu. ft. standard density
	(*c*) Air-horsepower output at stated inlet and delivery conditions. (Par. 120)
23 Locomotives	(*a*) Indicated horsepower
	(*b*) Drawbar horsepower. (Par. 154)
24 Gas Producers	(*a*) Pounds of fuel as fired per hour, of stated high calorific value (Par. 121)
	(*b*) Hot-gas output: cu. ft. of dry gas per hour, at stated temperature and pressure, and stated high calorific value

	(c) Cold-gas output: cu. ft. of dry gas per hour at 68 deg. fahr. and one standard atmosphere (d) Heat output per hour in hot gas (e) Heat output per hour in cold gas
25 Gas and Oil Engines	(a) Brake horsepower (b) Indicated horsepower. (Par. 115)
26 Hydraulic Turbines	Brake horsepower
27 Hydraulic Turbo-Generators	Net kilowatts at the generator terminals. (Par. 114)
28 Condensers	Heat transferred per hour, at stated vacuum, inlet and outlet circulating-water temperatures, and cubic feet of gases discharged by air pump per hour, measured at 68 deg. fahr. and one standard atmosphere. (Pars. 122–125)
29 Evaporators	(a) Heat transferred per hour at stated temperature of evaporation, and stated temperature and pressure of steam supply. (Pars. 122–126) (b) Pounds of raw liquor per hour (c) Pounds of concentrate per hour
30 Feedwater Heaters and Fuel-Oil Heaters	Heat transferred per hour at stated steam pressure and temperature and at stated inlet and outlet water or oil temperatures. (Pars. 122–128)
31 Oil Coolers	Heat transferred per hour, at stated inlet and outlet oil temperatures, and stated inlet and outlet cooling-water temperatures. (Pars. 122–128)
32 Economizers	Heat transferred per hour at stated pounds of flue gases per hour, inlet gas temperature and inlet and outlet water temperatures. (Pars. 122–128)
33 Cooling Towers and Cooling Ponds	Heat dissipated per hour at stated inlet and outlet water temperatures, stated air temperatures and humidity
34 Refrigerating Machines	(a) Heat absorbed per hour at stated head pressure and stated suction or cooler pressure. (Par. 122) (b) Tons refrigeration per 24 hrs. at stated head pressure, and stated suction or cooler pressure. (Par. 129)

TABLE 3 UNITS OF PERFORMANCE

	Apparatus	Quantities and Units	Conversion Relation
35	Boilers (including firing equipment and superheaters)	(a) Efficiency of boiler, superheater and furnace: ratio of heat units output to high calorific value of fuel as fired	
	Solid Fuels only	(b) Rate of combustion in lb. of fuel as fired per sq. ft. of grate surface per hour. (Par. 131)	
	All Fuels	(c) Rate of combustion in lb. of fuel as fired per cu. ft. of furnace volume. (Par. 132) (d) Heat transferred per sq. ft. of heating surface per hour. (Par. 122) (e) Heat developed per sq. ft. of grate surface per hour. (Par. 131)	
36	Reciprocating Engines	(a) Heat supplied per $\left\{\begin{matrix}\text{i.hp-hr.}\\ \text{b.hp-hr.}\end{matrix}\right\}$ (Pars. 140, 141)	
		(b) Thermal efficiency referred to $\left\{\begin{matrix}\text{i.hp.}\\ \text{b.hp.}\end{matrix}\right\}$ (Pars. 134–136)	$\frac{2545}{\text{(Item } a)}$
		(c) Rankine efficiency referred to $\left\{\begin{matrix}\text{i.hp.}\\ \text{b.hp.}\end{matrix}\right\}$ (Pars. 144–147) (d) Water rate, pounds of steam per $\left\{\begin{matrix}\text{i.hp-hr.}\\ \text{b.hp-hr.}\end{matrix}\right\}$ (Par. 152)	
37	Steam Turbines	(a) Heat supplied per b.hp-hr. (Pars. 140, 141)	
		(b) Thermal efficiency. (Pars. 134–136)	$\frac{2545}{\text{(Item } a)}$
		(c) Rankine efficiency. (Pars. 144–147) (d) Water rate, pounds of steam per b.hp-hr. (Par. 152)	
38	Steam-Engine Generators and Turbo-Generators	(a) Heat supplied per net kw-hr. (Pars. 114, 140, 141) (b) Thermal efficiency. (Pars. 134–136) (c) Rankine efficiency referred to net kw. (Pars. 144, 147) (d) Water rate, lb. of steam per net kw-hr. (Pars. 114–152)	
39	Steam-Driven Pumping Engines	(a) Heat supplied per water hp-hr. (Pars. 140, 141)	
		(b) Thermal efficiency (Pars. 134–136) referred to water hp.	$\frac{2545}{\text{(Item } a)}$
		(c) Water rate, lb. of steam per water hp-hr. (Par. 152)	
40	Steam-Driven Compressors, Blowers and Fans	(a) Heat supplied per air hp-hr. (Pars. 140, 141)	
		(b) Thermal efficiency. (Pars. 134–136)	$\frac{2545}{\text{(Item } a)}$
		(c) Water rate, lb. of steam per air hp-hr. (Par. 152) (d) Gross, (e) Net, (f) Indicated: horsepower per cu. ft. dry free air per min. (g) Water rate per i.hp-hr. (h) Volumetric efficiency (i) Compression efficiency (j) Mechanical efficiency (k) Overall efficiency	
41	Direct-Drive Steam Plants	(a) Fuel rate, lb. of fuel as fired per $\left\{\begin{matrix}\text{i.hp-hr.}\\ \text{b.hp-hr.}\end{matrix}\right\}$ (Par. 154) (b) Water rate, lb. of steam generated per $\left\{\begin{matrix}\text{i.hp-hr.}\\ \text{b.hp-hr.}\end{matrix}\right\}$ (Par. 152) (c) Heat in fuel, per $\left\{\begin{matrix}\text{i.hp-hr.}\\ \text{b.hp-hr.}\end{matrix}\right\}$ (Pars. 140, 141)	
		(d) Thermal efficiency referred to $\left\{\begin{matrix}\text{i.hp.}\\ \text{b.hp.}\end{matrix}\right\}$ (Pars. 134, 138)	$\frac{2545}{\text{(Item c)}}$
42	Steam-Electric Plants	(a) Fuel rate, lb. of fuel as fired per net kw-hr. (Pars. 114, 154) (b) Water rate, lb. of steam generated per net kw-hr. (Par. 148) (c) Heat in fuel per net kw-hr. (Pars. 114–116 and 140, 141)	
		(d) Thermal efficiency, overall, referred to net kw. (Pars. 132–138)	$\frac{3413}{\text{(Item c)}}$
43	Steam Pumping Plants	(a) Fuel rate, lb. of fuel as fired, per water hp-hr. (Pars. 119, 154) (b) Water rate, lb. of steam generated per water hp-hr. (Pars. 119, 148) (c) Heat in fuel per water hp-hr. (Pars. 119, 140, 141)	
		(d) Thermal efficiency, referred to water hp. (Pars. 119, 132–138)	$\frac{2545}{\text{(Item c)}}$
44	Steam Air-Machinery Plants	(a) Fuel rate, lb. of fuel per air hp-hr. (Pars. 120, 154) (b) Water rate, lb. of steam generated per air hp-hr. (Pars. 120, 152) (c) Heat in fuel, per air hp-hr. (Pars. 120, 141)	
		(d) Thermal efficiency, referred to air hp. (Pars. 120, 134, 138)	$\frac{2545}{\text{(Item c)}}$
45	Steam Locomotives	(a) Fuel rate, lb. of fuel as fired per i.hp-hr. (Par. 154) (b) Fuel rate, lb. of dry fuel as fired per drawbar hp-hr. (Pars. 154, 155) (c) Water rate, lb. of steam per i.hp-hr. (d) Water rate, lb. of steam per drawbar hp-hr. (Par. 152) (e) Fuel rate, lb. of fuel as fired	

		hp-hr. (Pars. 140, 141, 155)	
		(*g*) Thermal efficiency referred to drawbar hp-hr. (Pars. 134, 136, 155)	2545 / (Item *f*)
46	Gas Producers	(*a*) Hot-gas efficiency; ratio of high calorific value plus sensible heat above room temp. in hot gas, to the high calorific value of fuel as fired. (Par. 121)	
		(*b*) Cold-gas efficiency; ratio of high calorific value of gas to high calorific value of fuel as fired. (Par. 121)	
47	Internal-Combustion Engines	(*a*) Fuel rate, lb. of fuel as burned per {net i.bp-hr. / net b.hp-hr.} (Par. 154)	
		(*b*) Fuel rate, cu. ft. of dry gas of stated high cal. value at 68 deg. fahr. and one standard atmosphere, per {i.hp-hr. / b.hp-hr.}	
		(*c*) Heat supplied per {i.hp-hr. / b.hp-hr.} (Pars. 140, 141)	2545 / (Item *c*)
		(*d*) Thermal efficiency referred to {i.hp-hr. / b.hp-hr.}	2545 / (Item *c*)
		(*e*) Otto or Brayton efficiency referred to {i.hp-hr. / b.hp-hr.} (Pars. 144, 149–151)	
48	Gas- or Oil-Electric Units	(*a*) Fuel rate, lb. of fuel as burned per net kw. (Pars. 154, 114, 116)	
		(*b*) Fuel rate, cu. ft. of dry gas of stated high cal. value at 68 deg. fahr. and one standard atmosphere per net kw-hr.	
		(*c*) Heat supplied per net kw-hr. (Pars. 140, 141)	3413 / (Item *c*)
		(*d*) Thermal efficiency. (Pars. 134–137)	
		(*e*) Otto or Brayton efficiency referred to net kw. (Pars. 144, 149–151)	
49	Gas-Producer Plants	(*a*) Fuel rate, lb. of fuel as fired per net {i.hp-hr. / b.hp-hr.} (Pars. 115, 154)	
		(*b*) Heat in fuel per net {i.hp-hr. / b.hp-hr.} Pars. 140, 141)	
		(*c*) Thermal efficiency referred to {i.hp-hr. / b.hp-hr.} (Pars. 134–137)	2545 / (Item *c*)
50	Hydraulic Turbines	Efficiency of turbine; ratio of brake horsepower to water horsepower. (Par. 119)	
51	Hydraulic Turbo-Generators	Efficiency of unit; ratio of net electrical hp. to water hp. (Pars. 114–119)	
52	Surface Condensers	(*a*) Heat transferred per sq. ft. of cooling surface under stated conditions of vacuum, inlet and outlet circulating-water temperatures and cu. ft. of gases discharged per hour, at 68 deg. fahr. and one atmosphere. (Pars. 123, 124)	
		(*b*) Heat-transmission coefficient. (Par. 157)	
53	Evaporators	(*a*) Heat transferred per hour, with stated conditions of steam supply, temperature and pressure. (Pars. 126, 127)	
		(*b*) lb. of steam per lb. of distillate	
		(*c*) lb. of steam per lb. of concentrate	
54	Closed Feedwater Heaters and Fuel-Oil Heaters	(*a*) Heat transferred per sq. ft. of heating surface per hour at stated conditions of steam supply, and stated inlet and	
		cient	
55	Oil Coolers	(*a*) Heat transferred per sq. ft. of cooling surface per hour, at stated inlet and outlet oil temperatures, and stated inlet and outlet cooling-water temperatures. (Par. 128)	
		(*b*) Heat-transmission coefficient. (Par. 157)	
56	Economizers	(*a*) Heat transferred per sq. ft. of heating surface per hour at stated lb. of flue gases per hour, inlet flue-gas temperature and inlet and outlet water temperatures. (Par. 128)	
		(*b*) Heat-transmission coefficient. (Par. 157)	
57	Cooling Towers	(*a*) Efficiency. (Par. 158)	
58	Steam-Driven Refrigerating Machines	(*a*) Heat supplied in steam per ton of refrigeration, at stated conditions. (Pars. 129, 154)	
		(*b*) Coefficient of performance; ratio of heat abstracted to indicated work, expressed in B.t.u.	
		(*c*) Water rate, lb. of steam per ton of refrigeration, at stated conditions. (Pars. 129, 148)	

NOTES ON DATA

101 In order to render terminology consistent, the following symbols in frequent use are adopted:

H = heat content of the steam (Par. 111)
h = heat content of the liquid (Par. 111)
L = latent heat, or heat of vaporization
C_p = specific heat at constant pressure
C_v = specific heat at constant volume
V = specific volume of the vapor
V' = specific volume of the liquid
$u = V - V'$
E_o = Internal energy
P = pressure, lb. per sq. in. abs.
N = entropy of steam
n = entropy of liquid
$I = E - h$
J = mechanical equivalent of heat
A = heat equivalent of work = $1/J$
T = temperature, deg. fahr. abs.
W = work
w = weight
Q = quantity of heat in general; not to be used for denoting the property of a particular substance in a particular state.

102 Congress has never fully exercised its constitutional power of fixing the standards of weights and measures throughout the United States. The Bureau of Standards is now the legal custodian of the standards; and in the absence of specific action to the contrary by Congress, its practice in determining the values of lengths and masses is authoritative.

103 The ultimate standard of length is the international prototype meter, of which the Bureau has the two official copies assigned by lot to the United States. Determinations of length are referred to the ultimate standard through these copies by using the relation 1 meter = 39.37 in. Similarly, the ultimate standard of mass is the international prototype kilogram, of which two official copies are in the custody of the Bureau of Standards; and determinations of mass are referred to the kilogram by using the relation 1 lb. = 0.4535924 kg. There is no legally established United States primary standard yard bar or pound mass, and the adoption of the numerical relations mentioned above is, in effect, a definition of the foot and the pound.

104 For further information, see The History of the Standard Weights and Measures of the United States, by L. A. Fischer, *Bulletin* of the Bureau of Standards, Vol. 1, p. 365 (1905).

105 *International Standard Gravity*, adopted in 1901 by the Com-

mittee of the International Bureau of Weights and Measures, has the value.

$$g = 980.665 \text{ cm./sec.}^2 = 32.1740 \text{ ft./sec.}^2$$

which is the actual value of this acceleration at sea level and about 45 deg. latitude. At other latitudes, and at sea level, the ratio of local to standard gravity is as shown in the following table:

Latitude, (deg.)	g (local) / g (standard)	Latitude, (deg.)	g (local) / g (standard)
0	0.9973	50	1.0004
10	0.9975	60	1.0013
20	0.9979	70	1.0020
30	0.9986	80	1.0024
40	0.9995	90	1.0026

For higher altitudes, subtract 1 part in 10,000 for each 1000 ft. above sea level. At an elevation of 10,000 feet at the equator, local gravity is about 1 part in 79 less than standard gravity. For latitudes between 20 deg. and 70 deg. and altitudes below 5000 ft., the maximum difference between local and standard gravity is about 1 part in 400, an amount which is ordinarily negligible for engineering purposes.

106 For the mechanical equivalent of heat, the value

$$J = 778 \text{ ft-lb. per B.t.u.}$$

is adopted: it is equivalent to 1 mean calory = 4.186 true joules.

Other values which have been used in some of the recent steam tables are: Mollier (1906), 778.28; Marks and Davis (1916), 777.52; Goodenough (1914), 777.64; Callendar[1] (1915), 777.8. The greatest difference of any of these values from 778.00 is about 1 in 1620, an amount which is devoid of physical significance because the uncertainty of the value is at least 1 part in 500 and perhaps 1 in 200. The 15 deg. calory is known to about 1 part in 2000, and the mean calory is known to be nearly the same precisim as the 15-deg. calory. But the difference between the two is not so accurately known, even its sign being uncertain. In view of this fact it is quite evident that in the value J = 778 ft-lb. per mean B.t.u., even the 8 is not certain, and that the use of additional figures beyond the decimal point is a purely illusory refinement.

107 With J = 778 ft-lb. per B.t.u. we have

$$1 \text{ horsepower-hour} = \frac{1{,}980{,}000}{778} = 2544.987 + \text{B.t.u.}$$

$$1 \text{ kilowatt-hour} = \frac{1{,}980{,}000}{778 \times 0.745702} = 3412.874 + \text{B.t.u.}$$

Since the value 778 is uncertain by more than one unit, the use of decimal places in the foregoing values is a pure waste of time and they are abbreviated to 2545 and 3413.

108 *Absolute Temperature* in fahrenheit degrees is denoted by $T°$, and temperature on the ordinary Fahrenheit scale by $t°$, the relation between the two being

$$T° = t° + 459.6$$

and the absolute temperature of the ice point being $T_o = 491.6$. The values are uncertain by about one unit in the last place given. For all ordinary engineering purposes, such as reductions of gas volumes, the values 460 and 492 are more than sufficiently accurate.

109 *Ice Point and Steam Point.* The ice point is 32 deg. fahr. and the steam point 212 deg. fahr., both at one standard atmosphere.

110 *Internal Energy of a Substance.* When a pound of substance is brought from one state to another, for example, when a pound of water at 100 deg. fahr. and 50 lb. per sq. in. pressure is changed into steam at 100 lb. per sq. in. pressure and 70 deg. superheat, the amount of heat required for the change is not definite but depends altogether on the "path" of the change, i.e., on the series of intermediate states. But the sum of the heat put into, and the heat equivalent of the work done on the pound of substance during the change of state is definite and depends only on the initial and final states and not on, the path of the change. This sum is the value, expressed in heat units, of the energy that must be added to the pound of substance to produce the change, or it is the increase of the *internal energy*, in B.t.u. per lb., during the change. Since we are always concerned with *changes* of internal energy and not with absolute values, the internal energy may arbitrarily be set equal to zero at any convenient standard or normal state, such as 32 deg. fahr. and one atmosphere pressure. When such a convention has been adopted, the value of the internal energy in any other state is thereby fixed; and if the necessary data are available, it may be tabulated. Internal energy is denoted by the symbol E and expressed in mean B.t.u. per lb. of substance.

111 *Heat Content.* Let V be the volume in cubic feet, and E the internal energy in B.t.u. of one pound of a fluid at the pressure p in lb. per sq. in. Then the important quantity

$$H = E + \frac{144pV}{J} = E + 144\ ApV \text{ B.t.u. per lb.}$$

has been called the "total heat," "heat of formation" or "heat content" of the fluid, no one of the names being very satisfactory. The first is the most usual; but the necessity of using the adjective "total" in its ordinary sense sometimes makes it difficult to avoid ambiguity when the word is also being used with a special technical meaning in the compound noun "total heat." The name "heat content" will therefore be used for the quantity denoted above by H. When the substance is all in the liquid state, the symbol h will be used instead of H, and h thus denotes what is commonly called the "heat of the liquid."

112 The *standard density of mercury* at 32 deg. fahr. is 13.5955 grams per cu. cm. (Kaye & Laby, 1918.) The mean cubical expansion between 32 deg. fahr. and 212 deg. fahr. is 0.0001014 per deg., and from 32 deg. to 110 deg. fahr. it is 0.0001010.

113 *Units of Evaporation.* If it is desired to reduce B.t.u. output per hour to *units of evaporation*, divide by 1000. The use of the boiler horsepower (33,479 B.t.u. per hr.) is discontinued. The above changes are made for the following reasons: The boiler horsepower as originally standardized by the A.S.M.E. in 1889 was based on a conventional engine water rate of 30 lb. of steam per hp-hr. at 70 lb. gage pressure and feedwater at 100 deg. fahr. This corresponds to 34.5 lb. evaporated from and at 212 deg. fahr. At the present time, water rates vary from 8 lb. per b.hp. hr. in large condensing turbines to 50 or 60 lb. for small non-condensing units, and the boiler horsepower has no connection whatever with the water rate of the engine. It has never been used on the Continent or in England, and in the United States, marine boilers are rated in horsepower according to the hp. and water rate of the engines they serve. The unit has therefore become archaic, and it is better to state capacity in B.t.u., or in multiples of B.t.u. Under the boiler-horsepower definition, the unit of evaporation is the latent heat of vaporization at 212 deg., the value for which has varied with the steam tables from 965 to over 970 B.t.u. per lb. The statement of capacity or performance in B.t.u. is basic, and as the computations must in any case be made in B.t.u. at some point in the calculations, it is convenient to omit other arbitrary units as unnecessary. The objection that has been raised that capacity in B.t.u. gives large numbers is hardly worth consideration; it is only necessary to head the columns "units of evaporation" (1000 B.t.u.) which is but three per cent different from "equivalent evaporation" as now used, or "million B.t.u.," in which case the figures are smaller than when stated in boiler hp. The rating of boilers for size only, in square feet of heating surface, should be adopted; the area method has been in use for years in Europe, and in view of the fact that the ultimate steaming capacity per square foot is dependent solely on amount of fuel fired, it is a suitable unit, as not involving capacity.

114 *Net Output.* For any kind of separately excited engine or generator, the net output is expressed by the following formula:

Net kw. = gross kw. (main unit)—kw. excitation at collector rings

Net output where direct connected exciters are employed, is expressed by the following formula:

Net kw. = gross kw. (main unit) plus gross kw. exciter—kw. excitation at collector rings.

The gross kw. of both main unit and exciter is to be measured at the generator terminals. Further correction must be made if separately driven ventilating fans are employed, by substituting kw. to fan motor, or as determined by prior agreement, if the fan is not motor-driven.

115 *Net I.Hp.* for internal combustion engines, is the i.hp. of

[1] Callendar's fundamental value is 1 pound-degree centigrade = 1400.00 London foot-pounds, the British foot and pound mass being sensibly identical with the U. S. values, while the value of gravity at London is g = 981.19 cm./sec.^{2}.

eliminating all corrections. I.hp. is, strictly speaking, not a true output, inasmuch as it does not represent the power available for use at the engine shaft.

116 For complete power stations, gross output is the sum of the gross outputs of individual units. The difference between gross and net outputs is the kw. used for lighting, auxiliaries and house service and has the same character (necessary loss) for the complete plant as friction or excitation for an individual unit. It will be seen the term "net" is used to indicate that output which is available for use, outside the main unit, or plant, as the case may be.

117 *Rate of Combustion* is defined in two ways; the first is confined to solid fuels. For this case it is the pounds of fuel as fired per square foot of grate surface per hour.

118 Rate of combustion for the second case is used for all fuels, and comprises the pounds of fuel as fired per cubic foot of furnace volume per hour. For gas only, it may be stated as the cubic feet of gas as fired per cubic foot of furnace volume per hour.

119 Water horsepower is to be computed from the equation—

$$\text{Water hp.} = \frac{(\text{lb. of liquid per min.}) \times (\text{total head in ft.})}{33{,}000}$$

Both suction and discharge heads are to be total heads, as given by the impact tube, except in cases where the velocity head is less than 0.2 per cent of the total head. In the latter case static pressure, as usually taken by pressure gages, may be used.

If the total head is given as a difference of pressure, the value to be used in the foregoing equation is to be found from the formula

$$\text{Head in feet} = 4.476 \times \frac{\text{Pressure difference in lb. per sq. in.}}{\text{Actual density of water in lb. per cu. ft.}}$$

where $4.476 = 144/32.174$.

Water horsepower for pumps is the energy supplied to the water or other liquid by the pump in unit time. In the case of hydraulic turbines it is the available energy in the water to be employed by the turbine in unit time.

120 *Air Horsepower* (air hp.) is defined as the horsepower that would be required to compress the actual air output of the compressor or blower, if there were no friction and no clearance, if the inlet and outlet pressures were constant, and if the compression were adiabatic.

The suction and discharge pressures must be the total pressures as obtained with the impact tube, so as to include velocity head, except in those cases where the difference of velocity head at inlet and discharge is less than 0.2 per cent of the total head, in which case the usual static pressures given by pressure gages may be used.

121 *Calorific Value* as used in the tables, for solid and liquid fuels, is in all cases the high heat value per pound on complete combustion. The calorific value for gas is the high heat value per cubic foot. The low heat value is not to be used. The standardization on high heat values is adopted in order that all heat apparatus shall be charged with heat supplied, on the same basis. If the high heat values are used for some heat engines, and the low values for others, the efficiencies and other performance figures will not be comparable.

122 *B.t.u. Transferred per Hour.* In heat-transfer apparatus heat is transferred, or flows, from a region of higher to a region of lower temperature, without change of total quantity. The heat is nearly always given up or received by a fluid, and the rate of transfer is determined by measuring the rate at which the fluid gains or loses heat. Usually, as in surface condensers, evaporators, etc., both sides of the apparatus contain fluid, and measurements may be made on either of the fluids. If the apparatus is well insulated or is at nearly the same temperature as its surroundings so that the external heat transfer is negligible, the rate will be the same in which ever way it is found, but different methods may be most suitable in different cases.

123 *Surface Condensers.* Let M = total pounds of cooling water per hour and let t_1 and t_2 = its mean inlet and outlet temperatures. Then the rate of heat transfer is—

$$Q = Mc(t_2 - t_1) \text{ B.t.u. per hr.}$$

this being the rate at which the water receives heat.

per hour; let H_2 = heat content, in B.t.u. per lb., of the steam as it enters the condenser; and let h_2 = heat content in B.t.u. per lb. of the water in the hot well. Then the rate of heat transfer from the steam is—

$$Q = W(H_2 - h_2) \text{ B.t.u. per hr.}$$

The "heat of the liquid" h_2 may be found from the steam table if the back pressure is known, but the value of H_2 has to be determined indirectly because the dryness factor of the steam cannot well be observed, and H_2 can therefore not be found directly from the steam table.

125 The value of WH_2 is to be found from the equation

$$WH_2 = WH_1 - A - R$$

where H_1 = heat content of initial steam from the steam table
A = extraction in B.t.u. per hr.
R = heat lost by the engine to the surroundings in B.t.u. per hr. (commonly but incorrectly called "radiation loss").

(*a*) For reciprocating engines—

$$WH_2 = WH_1 - \text{i.hp.} \times 2545 - R$$
$$= WH_1 - \frac{\text{b.hp.} \times 2545 - R}{\text{mech. effy.}}$$

(*b*) For steam turbines—

$$WH_2 = WH_1 - \text{b.hp.} \times 2545$$

(*c*) For turbo-generators—

$$WH_2 = WH_1 - \frac{\text{kw.} \times 3413}{\text{generator effy.}}$$

For turbines the heat loss R and the bearing and gland friction are negligible: all other losses appear as reheat in the steam.

126 *Evaporators.* Let M = pounds evaporated per hour; h = heat content of the entering liquid in B.t.u. per lb. and H = heat content of the issuing vapor. Then the rate of heat transfer is—

$$Q = Mc(H - h) \text{ B.t.u. per hr.}$$

127 If the quality of the entering steam is known, so that its heat content may be found from the steam table, we also have—

$$Q = W(H_2 - h_2) \text{ B.t.u. per hr.}$$

where W = total pounds of steam condensed per hour
H_2 = heat content of entering steam
h_2 = heat content of condensed water.

When there is heat loss to the surroundings the second formula will give the higher result, and the first is to be preferred.

128 *Feedwater Heaters, Fuel-Oil Heaters, Coolers and Economizers.* The rate of heat transfer is—

$$Q = Mc(t_2 - t_1) \text{ B.t.u. per hr.}$$

where M = total pounds of water or oil passed through per hour,
c = the specific heat of the substance (for water $c = 1$)
$(t_2 - t_1)$ = the rise or fall of temperature.

129 *One Standard Ton of Refrigeration* is defined as the absorption of 288,000 B.t.u. irrespective of time.

The unit of capacity, one ton per day, will then be $\frac{288{,}000}{24 \times 60} = 200$ B.t.u. per min.

130 *Total B.t.u. per Hour Output in Steam from Boiler:*

$$Q = W(H_1 - h_2) \text{ B.t.u. per hr.}$$

where W = total pounds of water evaporated per hour
H_1 = heat content of the steam generated in B.t.u. per lb.
h_2 = heat content of feedwater in B.t.u. per lb.

H_1 and h_2 to be found from the steam table.

131 *Grate Surface* is defined as the total horizontal projected area of grates or stoker, including dump plates, ash crushers, etc. it is also stated as the total projected area of all surface supporting coal, within the front wall of the furnace. This definition will cover cases in which the bridge wall is undercut for ejection of refuse.

132 *Total Furnace Volume* is defined for horizontal return tubular boilers and water tube boilers as the cubical contents of the furnace between the grate and the first place of entry into or between tubes. It therefore includes the volume behind the bridge wall as in ordinary horizontal return tubular boiler settings, unless manifestly ineffective, (i.e., no gas flow taking place through it), as in the case of waste-heat boilers with auxiliary coal furnaces,

where one part of the furnace is out of action when the other is being used. For Scotch or other internally fired boilers it is the cubical contents of the furnace, flues and combustion chamber, up to the plane of first entry into the tubes.

133 *Heating Surface* for boilers and superheaters comprises the total area of all the surface in actual contact with the hot gases. This definition implies that tubes of water-tube boilers will be figured on outside diameter, and of fire-tube boilers, on inside diameter. The amount of boiler surface should be stated separately from superheater surface. The heat transfer is always to be figured on total heating surface.

Heating or cooling surface, for condensers, evaporators, feedwater heaters, oil heaters and oil coolers, will be figured on total surface in contact with both fluids, and based on outside diameter of tubes. Heating surface for economizers will be figured the same as for boilers and superheaters.

134 *Thermal Efficiency* based on any unit of output is defined as the heat equivalent of the work done divided by the heat supplied.

135 *The Heat of the Liquid*, for steam engines and turbines, is to be taken at the temperature corresponding to the back pressure.

136 *Thermal Efficiency* is expressed as follows:

For steam engines:

$$\text{Indicated thermal efficiency, } E_i = \frac{2545}{W_i(H_1 - h_2)}$$

For steam engines and turbines:

$$\text{Brake thermal efficiency, } E_b = \frac{2545}{W_b(H_1 - h_2)}$$

For engine-generators and turbo-generators:

$$\text{Combined thermal efficiency, } E_k = \frac{3413}{W_k(H_1 - h_2)}$$

where W_i = steam consumption referred to indicated horsepower
W_b = steam consumption referred to brake horsepower
W_k = steam consumption referred to net kilowatts
H_1 = heat content, B.t.u. per lb. at the throttle
h_2 = heat of the liquid, B.t.u. per lb., corresponding to pressure in exhaust.

137 *The Thermal Efficiencies* of the internal-combustion engine are expressed as follows:

$$\text{Indicated thermal efficiency, } E_i = \frac{2545}{Q_i}$$

$$\text{Brake thermal efficiency. } E_b = \frac{2545}{Q_b}$$

$$\text{Combined thermal efficiency, } E_k = \frac{3413}{Q_k}$$

where Q_i = B.t.u. per i.hp.
Q_b = B.t.u. per b.hp.
Q_k = B.t.u. per net kw.

138 The thermal efficiency for complete plants will be expressed in the same way, using i.hp., b.hp., net kw., water hp., air hp., etc., as the reference. For example, the *overall thermal efficiency* of a coal-fired electric plant is—

$$\frac{3413}{\text{Calorific value of coal} \times \text{lb. coal per net kw-hr.}}$$

139 It is to be noted that in present usage the terms "thermal efficiency" and "cycle" are not limited to the thermodynamic sense only. They are therefore not to be interpreted in the strictly special manner usual in thermodynamics, as used in the Code: their use in the general sense is established by custom and is perfectly understandable.

140 *Heat Supplied*, referred to any unit of output, is defined as the heat input per unit of output.

141 *Heat Supplied*, for steam engines and turbines, is expressed as the total heat content of the steam supplied less the heat of the liquid at exhaust pressure. For complete steam plants, for gas producers, internal-combustion engines and internal-combustion plants, it is expressed as the high calorific value of the fuel per lb. as fired, times the pounds fired.

142 *The Initial Steam Pressure* for any steam engine or turbine is defined as the average pressure obtained in the supply pipe directly preceding the throttle valve of the engine or turbine. The same definition will apply to any other apparatus using steam and using a stop valve to start or stop it.

143 *The Back Pressure or Exhaust Pressure* for steam engines or turbines is defined as the pressure obtained at or as near as possible to the exhaust flange, and it shall also be considered to be the pressure obtaining in the condenser, where the condenser is directly connected to the turbine or engine-exhaust flange (applied only to steam prime movers).

144 *Engine Efficiency* is the general term used for the ratio between heat input per unit of output for the ideal cycle, and heat input per unit of output for the actual engine. It may also be expressed as $\frac{E_i}{E_r}$, $\frac{E_b}{E_r}$ or $\frac{E_k}{E_r}$; and in other ways; all of which are simply transpositions of the same quantities. The ideal cycles are different for the different classes of prime movers. For steam engines and steam turbines, the ideal is the Rankine cycle, and the above ratio will be called the "Rankine efficiency." For explosion internal-combustion motors the Otto cycle is the ideal, and the ratio will be called the "Otto efficiency." For constant-pressure internal-combustion motors the Brayton cycle is the ideal, and the ratio will be called the "Brayton efficiency." Other cycles may be employed as ideals for comparison, as prime movers are developed, but are not required at present. The Carnot cycle, although it affords the highest thermal efficiency, is not employed in any commercial prime mover at present, and therefore is of no practical value in these codes.

145 *The Rankine Steam Cycle* consists of (*a*) admission at constant pressure and temperature, (*b*) isentropic expansion to the back pressure, (*c*) exhaust at constant pressure and temperature, (*d*) return to the boiler of the equivalent amount of feedwater, taken at the temperature and pressure of the exhaust steam; there is to be no heat leakage and no friction, so that all stages of the cycle are ideally perfect.

146 *Thermal Efficiency of the Rankine Cycle:*

$$E_r = \frac{H_1 - H_2}{H_1 - h_2}$$

where H_1 = heat content of steam, at initial condition
H_2 = heat content of steam after isentropic expansion
h_2 = heat of the liquid at exhaust pressure.

The foregoing formula is not exact because it neglects the work of the feed pump, but this is in fact negligible, so that the formula may be used without correction.

147 *Heat Input of the Rankine Cycle* is expressed as

$$\frac{(H_1 - h_2)\ 2545}{H_1 - H_2} = \frac{2545}{E_i} \text{ for i.hp.}$$

$$\frac{(H_1 - h_2)\ 2545}{H_1 - H_2} = \frac{2545}{E_b} \text{ for b.hp.}$$

$$\frac{(H_1 - h_2)\ 3413}{H_1 - H_2} = \frac{3413}{E_k} \text{ for net kw.}$$

148 *The Otto Cycle* consists of (*a*) adiabatic compression, (*b*) heating at constant volume (explosion), (*c*) adiabatic expansion to the original volume, and (*d*) cooling at constant volume (exhaust).

149 *The Brayton Cycle*, (of which the Diesel cycle is a modification), is defined as (*a*) adiabatic compression, (*b*) heating at constant pressure, (*c*) adiabatic expansion to the back pressure, and (*d*) exhaust at constant pressure.

150 *Thermal Efficiency of the Otto and Brayton Cycles* is expressed as

$$E_o = 1 - \left(\frac{P_a}{P_b}\right)^{\frac{\gamma - 1}{\gamma}} = 1 - \left(\frac{V_b}{V_a}\right)^{\gamma - 1}$$

where E_o = thermal efficiency of the Otto or Brayton cycle.
P_a and V_a = absolute pressure and volume at beginning of compression.
P_b and V_b = Absolute pressure and volume at end of compression.
γ = ratio of specific heats $\frac{C_p}{C_v}$ equals 1.41 when air, is used in compressive gas cycles.

(*Continued on page 821*)

AERONAUTICS

The Z R-2 Disaster. The Report of the Court of Inquiry into this disaster, issued in London in October, adds little information to what was previously available.

The cause of the accident in the opinion of the court was that the structure failed in the rear of the after-end cars and the hull broke in two while the ship was being subjected to rudder and elevator tests at a speed of about 45 to 50 knots.

It appears that almost extreme helm, with quick reversal, was being used at the time and the swing of the stern resulting from this maneuvering set up greater stresses in the hull framing than could be resisted.

The Aeronautical Research Committee and the Admiralty are conducting additional and independent investigations, the findings of which have not yet been published.

The editorial in *Engineering* from which the above information has been taken makes the comment to the effect that the airship was not, as might have been expected, the embodiment of the skill and experience of British airship designers as a whole. The disaster might possibly have been prevented by a very careful investigation of the design after one of the preliminary trials in which the weakness of some of the girders amidships became evident, as proved by the fact that these particular girders were reinforced before the final trial. (*Engineering*, vol. 112, no. 2911, Oct. 14, 1921, pp. 545, *g*)

The D.H. 29 Monoplane. Description of the new DeHaviland monoplane and of interest because it is the first commercial aeroplane designed and built in England with wings of the cantilever type. (In addition to the monoplane described here another one was built for the Air Ministry, the details of which are confidential.)

The wing is of thick section, high-lift type, with a high L_c maximum, giving the same landing speed for a much higher wing loading. The wing area of the monoplane designed to carry twelve people is the same as that of the D.H. 4, which was quite a small aeroplane and well known in this country.

The fuselage shows a total absence of wire bracing. The cabin portion of the fuselage is triangulated by deeply splined H-section diagonal struts, and it is of interest to note that three of these transmit the weight of the wing to the points on the lower longerons where the struts of the undercarriage are attached.

In section the fuselage is usual, inasmuch as the floor is considerably wider than the deck. The main reason for this appears to be the desire to get a wide base for the attachment of the undercarriage struts.

In the design of the passenger cabin a consistent effort was made to secure comfort and safety for the passengers. In connection with the latter, emergency doors were provided in the roof. Also plywood construction of the fuselage was adopted in conjunction with water-tight door joints, in order to enable the machine to remain afloat for a considerable period, should a forced descent in the sea ever have to be made.

The engine is powered with a 450-hp. Napier-Lion engine mounted high in the nose. The radiator is placed below and behind the engine. As to the gasoline tanks, two of them are placed in the leading edge of the wing, one on each side. It is intended to employ a low-pressure gasoline system.

The monoplane is of particular interest as indicating a determined attempt to test out to the limit the possibilities of cantilever wing construction. In this construction experience with the D.H. 29 is enlightening in showing that some of the assembly difficulties with a cantilever wing are not as formidable as they were believed to be. Thus, it has been generally believed that with thick section high-lift wings it was necessary to have a rigid covering, such as plywood and sheet metal, as such wings have been thought to be very sensitive to quite minute changes in curvature, such as may be caused by a slight sagging of the covering. Altogether the D.H. 29 is covered with fabric in the ordinary way and there does not appear to have been any trouble due to this cause.

The details of control, especially the lateral control at or near the stalling angle, are given in the original article. (*Flight*, vol. 13, no. 39/666, Sept. 29, 1921, pp. 641–647, illustrated, *dA*)

AIR MACHINERY (See Refrigerating Engineering)

CORROSION

Corrosion of Cast Iron

The Self-Corrosion of Cast Iron and Other Metals in Alkaline Soils, W. Nelson Smith and Dr. J. W. Shipley. Data of research carried out in Winnipeg, Canada, and covering the electrochemical phenomena underlying corrosion of metals in certain soils, soil analysis, effect of moisture content and salts in solution, and products of corrosion. The first of the authors is consulting electrical engineer of the Winnipeg Electric Railway Co., and the second is assistant professor of chemistry at the University of Manitoba.

The investigation was primarily undertaken in order to derive proof that the external corrosion of city water mains in areas where any stray electric current present would necessarily be flowing into the pipe and not out of it, must be due to the action of the soil and not to the passage of stray current, which can only dissolve iron where it leaves the pipe.

The experimental work was carried out both in the field and laboratory with pieces cut from cast-iron pipe and bars of cast iron immersed in various salts. The following conclusions were drawn:

1 The corrosion of cast iron by the salt solutions found in natural soil is readily accomplished under natural conditions without access of stray current. This corrosion is of the so-called graphitic pitting type, by which is meant the commonly observed condition of the material remaining in place, which is invariably of a soft, spongy texture with part of the iron dissolved out, the remainder resembling graphite in consistency.

2 Magnesium salts are the most corrosive of the soil salts, and magnesium sulphate, which was found wherever a cast-iron pipe had been destroyed, is apparently the most effective of the salts experimented with.

3 Local action induced by naturally occurring concentration cells may easily be a factor in the pitting of cast iron exposed to salts of varying concentration.

4 Slight pitting corrosion was found in pieces of cast iron exposed to the action of small samples of wet soil and intermittently heated, even in the short period of 40 days, and with only a limited supply of water as compared with conditions in natural ground, no impressed electromotive force being present.

The products of corrosion on cast-iron pipes were next investigated and it was found that they consisted mainly of metallic iron, ferrous oxide, ferric oxide, and silicious graphitic residue, in addition to which, however, were found also ferrous phosphate and iron sulphide, showing the great complexity of corrosion processes.

The moisture content is apparently an important element in the rapidity of corrosion on pipe. It was generally found that soils of Winnipeg and vicinity when in contact with iron can of themselves set up an appreciable electromotive force like that of a battery, amply sufficient to decompose the iron. Moreover, indications become available to the effect that lead and copper are also affected by self-corrosion.

Thus, a small new lead plate was buried in contact with a clay soil and some black surface soil in a sealed glass container, with plenty of moisture present, and when removed at the end of $4^1/_2$ months was found to be pitted with little cavities about as big as pin heads, which were filled with white pellets of crystallized lead sulphate. No heat was applied during the experiment. A copper ground plate buried below the basement floor of the Manitoba Government Telephone Exchange in St. Boniface, corroded in 18 months or less after installation.

As regards preventive treatment, it is stated that usual treatments with tar, dips and paints have generally proved futile, but the authors believe that the life of cast-iron pipe in a wet, salty soil could be lengthened considerably by backfilling the pipe trench with quartz sand or washed gravel rather than depending on a thin layer of paint.

E. L. C. Forster, chemist on the Dominion Health Board staff, has advised that a very small percentage of aluminum with cast iron has prevented microscopic shrinkage cracks in the surface of castings that otherwise formed when the casting cooled, and that this property was utilized in making munitions during the war. The absence of minute surface cracks might render the silicious coating of cast-iron pipe more impervious to salt solutions. Any method of casting pipe which could produce a flawless exterior coating of silicate, that would resemble enamel would certainly retard the solution of the iron. (Paper presented at the 10th General Professional Meeting of the Engineering Institute of Canada, Saskatoon, Aug. 11, 1921. *The Journal of The Engineering Institute of Canada*, vol. 4, no. 10, October, 1921, pp. 527–535, *ep*)

ENGINEERING MATERIALS (See also Corrosion)

Lafarge Quick-Hardening Cement, Edwin C. Eckel. Data on a cement developed during the war, of which the most remarkable property is that it hardens with great rapidity so as to make a good, heavy gun platform within 24 hr.

This new cement is a lime-aluminate and differs from normal portland cement in the almost total absence of silica; it is prepared by actual fusion and not by mere clinkering and is almost white in color.

It is made in a small blast furnace which is charged with coke, limestone and bauxite. When the furnace is in steady operation it turns out from 10 to 15 metric tons a day of fused slag, which, cooled and ground, is the new cement. It contains, roughly, 50 per cent lime, 40 per cent alumina and 10 per cent other additions, such as silica.

Its cost is said not to vary materially from that of the normal portland cement. It has a normal setting time but hardens, as mentioned above, with far greater rapidity. It is believed that it would be of practical advantage for use in marine work which has to be completed between two tides. It is said to possess great resistance to the decomposing effects of sea water and similar solutions, as indicated by the experience of an important railway in France. (*Engineering News-Record*, vol. 87, no. 14, Oct. 6, 1921, pp. 566–567, *d*)

Genelite, an Improved Bearing Alloy, E. G. Gilson. Data on a new synthetic bronze-graphite bearing material developed by the Research Laboratory of the General Electric Company. It is claimed that it does not seize nor score when bearing surfaces are permitted to run dry through negligence or accident.

The material has uniformly distributed throughout its mass approximately 40 per cent by volume of very finely divided graphite. It is made by thoroughly mixing the finely powdered oxides of the metals composing the bronze with sufficient graphite to completely reduce them and leave in excess of this amount the graphite content desired in the finished material. This reduction process must be carried on at temperatures below the welding point, and therefore the material cannot be cast, but is shaped by molding under high pressure while still in powdered form. As the powder does not flow readily under pressure, it is necessary to use a complicated mold and confine this operation to only the simplest shapes. The material cannot be machined easily by ordinary methods as it rapidly dulls the cutting tool. It grinds easily, however.

Genelite has not the physical characteristics of ordinary bronze. Its tensile strength and elongation are low and the ultimate strength and yield point are practically identical at 8000 lb. per sq. in. Under compression, however, it will withstand 50,000 lb. per sq. in. The structure of the material is of a porous nature and it will absorb from 2 to 3 per cent by weight of oil.

The self-lubricating property of genelite is taken advantage of in many applications, such as in tilting motors where the standard oil-ring practice cannot be used because the oil will run out of the bearings when tilted.

Owing to its spongy structure genelite should be given a greater allowance for pressed fits than is customary with other materials and it need not be held to such close limits. (*General Electric Review*, vol. 24, no. 11, Nov. 1921, pp. 940–951, 3 figs., *d*)

FUELS AND FIRING (See also Transportation)

Cheap Oxygen Manufacture

The Influence of Cheap Oxygen on Economy of Fuel and of Time, E. A. W. Jefferies. The author describes a process of oxygen separation which, in general, consists of liquefying the air by compression and expansion. The nitrogen is next distilled off, but the distillation is carried on under the same pressure to which the air is originally compressed. By this method the nitrogen leaves the steam under the original pressure and can then be heated to increase its volume and power capacity and used in a piston engine to drive the compressor.

For this purpose only a comparatively little heat is required, so that the entire process requires only fuel, but not external power, to operate.

The new method has been demonstrated on a large scale by the Government in the separation of helium from the natural gases of Texas.

A claim is made that oxygen can be produced in large quantities by this process at a price of the order of 8 cents per thousand cubic feet.

The remainder of the paper is devoted to the use of oxygen in gas producers, open-hearth furnaces, blast furnaces, and industrial applications, and made possible its low price. (*Association of Iron and Steel Electrical Engineers*, vol. 3, no. 10, October 1921, pp. 471–477, *dg*)

Powdered-Coal Firing in Industrial Plants. Report of Commission appointed by the Minister of Public Works to investigate the best methods of utilization of fuels, reprinted from an official publication of the French Government. The purpose of the report was to investigate in view of the extensive application of powdered-coal firing in America to what extent the same would be suitable under French conditions. Only the conclusions are given here.

The report cites the following points in favor of powdered-coal firing—

1 The very high utilization of the value of the fuel whether the latter belongs to the class of rich or poor fuel;

2 The possibility of burning successfully low-grade fuels, some of which could not otherwise be burned at all today; easy handling of the fire, its instantaneous starting and extinction, and, under certain conditions, a great flexibility in regulation.

As against the employment of powdered fuel are cited the liability to accidents, troubles due to ash and clinker formation and high first cost of installation.

As regards these objectionable features, it is pointed out, however, that accident liability may be largely reduced by greater knowledge of past experiences with this fuel and by proper and careful precautions. The trouble due to ash and clinker formation appears to have been already largely eliminated by the use and good handling of suitable apparatus, and as regards the high first cost of installation it is stated that in certain cases this may be more than compensated for by economies of operation due either to lessened consumption or the use of cheaper grades of fuel.

On the whole the report recommends the subject of powdered-fuel burning to the earnest attention of French industries. (*Memoires de la Société des Ingénieurs Civils de France*, vol. 74, series 8, nos. 4, 5 and 6, April to June 1921, pp. 123–172, *g*)

Pelton-Wheel Bucket Efficiencies

Comparative Tests on Pelton-Wheel Buckets of Different Inclinations. An investigation for the purpose of determining directly the inclination of the buckets that gives the best efficiency, carried out at the Hydraulic Laboratory of the Engineering Division, Kyushu University.

The wheel is 520 mm. (20 in.) in diameter and designed to develop 6 b.hp. under a head of 30 m. (98.4 ft.) at 400 r.p.m. The wheel carries 22 ellipsoidal buckets.

Experiments were made with four different inclinations of buckets and the results are presented in the form of tables and curves. It was found that when the central ridges stand at right angles to the jet axis at the mean position between the beginning and end of full jet, the best efficiencies are obtained for all gates except one-quarter gate. At seven-eighths gate, which corresponds nearly to the normal load of the wheel, case 2 has an efficiency of 83.2

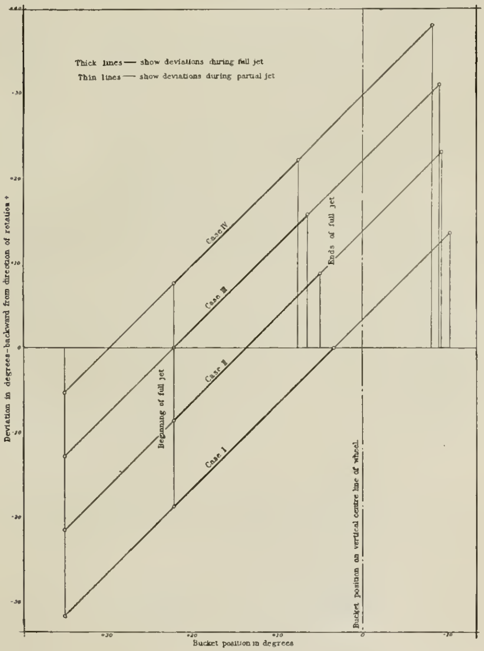

Fig. 1 Deviation of Bucket Planes from Normal to Jet Axis

per cent, exactly 10 per cent greater than in case 4 when the relative entrance velocity of the jet is at right angles to the ridge at the same mean position of the bucket. In the order of efficiencies, case 1 is next to case 2, then comes case 3 and lastly case 4. These variations of maximum efficiencies in the four cases may be explained briefly as follows: When it is remembered that the buckets under consideration are so shaped that the normal cross-sections of the double ellipsoidal deflecting surface of the bucket are all at right angles to the plane containing the central ridge and the exit edges (hereafter called the bucket plane), it is evident that the impulsive action of the jet will be most efficient if the buckets can move parallel to themselves standing always at right angles to the jet, in which case the absolute deflection of the mid particles of the jet will always take place on the axial plane through the jet parallel to the wheel axis. Actually, the bucket's inclination against the jet axis continually changes and the buckets so disposed as to make them move in a way nearest to the ideal motion above mentioned, at least during the most important part of the range of jet action will have the highest efficiency. From these considerations it ciency of the four experimented upon. The deviation of the bucket plane from the normal to the jet axis in the four cases are shown in Fig. 1, in which it will be observed that the deviation is least in case 2. The maximum deviation in this case is ± 8 deg.5 min., while it is + 22 deg. 14 min. in case 4. When the deviation is excessive as in the latter case, that is to say, when the bucket plane is much inclined toward the impinging jet, the deflected stream is forced downward considerably from the axial plane of the jet parallel to the wheel axis, which phenomenon was clearly observable during the tests through glass holes on the cover of the wheel; as a consequence of this, the torque exerted by the impinging jet is much reduced.

If the central ridge be not parallel to the plane containing the exit edges as in some buckets, it seems advisable so to fix the buckets that the jet shall be at right angles to the major axial plane, if it may be so called, of the double ellipsoid at the mean position of bucket between the beginning and end of the full jet. (*Memoirs of the College of Engineering, Kyushu Imperial University*, Fukuoka, vol. 2, no. 3, pp. 143–174, 16 figs., *e*)

INTERNAL-COMBUSTION ENGINEERING

New Nelseco Diesel Engine. Details of a 600-b.hp. marine Diesel engine. In introducing the subject the author makes a significant statement to the effect that from his personal knowledge of the factories in this country and Europe there is no single European country whose compound Diesel and surface-ignition engine facilities can equal those of the eight leading factories of this country.

The New London Ship and Engine Company, the builders of the Nelseco engine, have in the past devoted their facilities principally to the construction of submarine-type engines for the United States and foreign navies, but expect now to give more attention to the commercial craft field.

The new engine weighs 53 tons overall, or 191 lb. per b.hp., and is chiefly designed for use in direct drive on small commercial vessels, such as ferries, tugs, etc. For large freighters, passenger vessels and tankers it may be used in conjunction with electric transmission, several engines being employed when necessary.

As regards the technical features, it may be mentioned that the six working cylinders for the engine are in line with the single three-stage air compressor at the forward end. In this air compressor the piston is driven from the crankshaft by means of a connecting rod and crosshead. Because of this the compressor cylinders are made entirely separate from the crankcase, which provides an accessible machine and avoids all trouble due to lubricating oil in the cylinders.

Independently driven circulating-water and lubricating-oil pumps are provided, but direct-connected pumps may be fitted at the forward end if desired.

For the lubricating of the engine, the system can best be described by calling it a gravity forced feed. With this system the lubricating oil flows from the gravity tank which is at a sufficient height above the engine crankshaft to give the proper pressure to the main bearings, then through holes in the crankshaft to the crankpins, and up the inside of the connecting rods to the wristpins. The crankcase is enclosed and all surplus oil drains to a suitably formed trough in the bottom of the bedplate, whence it is pumped back through suitable strainers to the gravity tank. All of the important bearings are thus under forced lubrication and a free flow of oil is circulating through them at all times. The camshaft parts are oiled by splash from oil carried in the bottom of the trough of the camshaft casings. All cylinders and exhaust-valve stems are taken care of by mechanical oilers, and the minor valve-gear bearings are fitted with oil cups for hand oiling. (*The Motorship*, vol. 6, no. 10, Oct. 1921, pp. 798–801, illustrated, *d*)

The Open-Fronted Surface-Ignition Engine, F. G. Butt-Gow. General discussion of design of semi-Diesel engines, with particular attention to the differences between the closed type and the open for marine service.

The author compares the two types in detail from the point of view of manufacture and operation and shows that on the whole the crankcase is rather easier to build in the open type than in the

closed type. The cylinders of the two types are not very different, though possibly in the closed engines they may be slightly longer. The piston on the open engine may be made shorter as it does not have to perform the duties of a slide in the cylinder walls which serve as guides. The general conclusion to which the author arrives is that the cost of manufacture of the open engine should not be very much more than that of the closed engine, and in the larger sizes, that is, 60 to 100 b.hp. per cylinder, it ought to be less, owing to the use of smaller castings and subdivision of parts. This is especially so in view of the difference of lubrication.

On the closed engine the same system of forced lubrication is generally used. The crankpin brasses are usually supplied with oil by means of banjo rings or centrifugal lubrication. In the open-fronted engine the lubrication is practically the same as on a marine steam engine; either an ordinary open-drip system may be fitted or a drip with side feeds.

As regards operation, it is claimed that the closed engine shows more wear in the cylinder and bearings, the former being ascribed by the author to the use of a trunk piston. In the open engine the main bearings, top and bottom ends and guides, are in full view all the time, while in the closed engine the main bearings only are in sight. There is really no way to judge reliably of the extent to which the crankpin brasses are supplied with oil.

The following data as to lubricating-oil consumption are cited by the author:

Bolnes 130 b.hp., 0.005 pint per b.hp. per hr.

Closed type 160 b.hp., 0.010 pint per b.hp. per hr.

The question of adjustments is next discussed and the author shows that gudgeon-pin and crankpin adjustments are very much simpler and easier on the open-type than on the closed-type engine.

Various types of open crankcase engines are described and illustrated—namely, the Reliable, the Bolnes, the Grei, Lambert and Adie, Stallard double-acting hot-bulb engine and the Summér. Of these, the Lambert and Adie is of interest as it was first designed to work on the Brons (known in America as the Hvid) system of ignition, but can be adapted to surface ignition. (*Transactions of the Institute of Marine Engineers*, vol. 33, September, 1921, original paper pp. 239–269, 21 figs., and discussion pp. 270–278, *cA*)

Supercharging Engines and Their Uses

Supercharging Engines, G. H. T. Alston. General discussion of the subject, of which the part abstracted here deals with the application of supercharging engines for various purposes.

In particular, in considering the application of supercharging to road motor vehicles, the author calls attention to the fact that much would depend upon the method employed. If the supercharging were to be in action all the time, the effect would be equivalent to fitting a larger engine, or, conversely, an engine of smaller cubic capacity could be used and the same power maintained.

Supercharging can be applied also so that the capacity of the engine be such that the power developed at nearly full throttle but without supercharging would be that required during the greater part of the time, supercharging being only resorted to when greater than average power was required. Such an engine would be more economical as regards fuel consumption than one running normally under reduced throttle conditions.

There is therefore every reason to believe that supercharging, so applied, would lead to a large reduction in fuel costs per ton-mile on give-and-take routes. In order, however, to reap the maximum advantage from supercharging, it would be necessary to utilize to the fullest extent the accelerative powers possessed by such an engine. In such an application of supercharging it should be possible, without demanding any additional attention from the driver, to so control the engine (possibly by means of a permanent restriction in the induction pipe leading to the supercharging device) that only at slow speeds, on any gear, full supercharge is available at full throttle opening. As the speed increases, the restriction begins to take effect so that the supply of mixture is reduced.

By some such means it would be impossible to obtain full supercharge at any except reduced speeds, thereby avoiding seriously overloading the engine. A supercharge valve, under control of a governor, could operate in the same way, but it might, perhaps, be rather more easily put out of order. In Fig. 2 is illustrated an estimated power curve showing the effect of operating under these conditions compared with a power curve from a normal type of engine of slightly larger capacity but developing the same maximum brake horsepower.

It will be seen from these curves that the same maximum brake

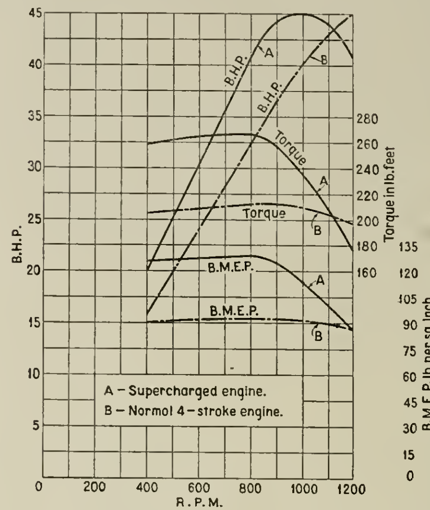

Fig. 2 Power Curves of Normal and Supercharged Engines

horsepower is available from each type of engine, but it is obtained from the supercharging engine at a much reduced speed, and that from this speed upward revolutions per minute are gained at the expense of the brake mean effective pressure, and that the brake horsepower therefore remains practically constant over a fairly wide speed range.

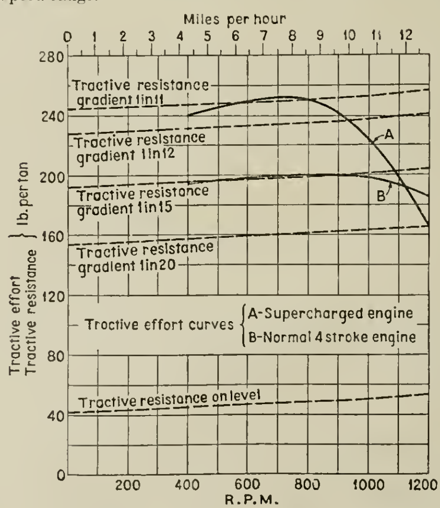

Fig. 3 Tractive-Effort Curves of Normal and Supercharged Engines

The aim has been, not to develop a maximum horsepower at maximum supercharge and revolutions per minute, but at a lower speed, so that the maximum brake horsepower is maintained over a considerable speed range by, as indicated above, exchanging brake mean effective pressure for revolutions per minute. In Fig. 3 are shown the tractive-effort curves for two different heavy-type

is fitted with a supercharging engine capable of giving a power curve as (a) Fig. 2, while in the other is installed a normal four-cycle engine whose power curve is as (b). Road-resistance curves are both level and certain gradients are also shown, from which it is apparent that an engine with a power curve such as (a) would have a greater capacity for top-gear work.

These curves also show that the supercharging engine could still propel its load at a speed of $8^1/_2$ m.p.h. on a gradient of 1 in 11, and at 10 m.p.h. on a gradient of 1 in 12, whereas with the normal four-cycle engine of the same maximum horsepower the speed would be reduced to 10 m.p.h. on a gradient of 1 in 15, and would then probably require a change of gear. Since hills of 1 in 12 and steeper are the exception on the main roads, it is safe to assume that the supercharging engine would be able to maintain its normal speed of 12 m.p.h. on top gear except when compelled to slow down for considerations other than gradients.

In a commercial vehicle of the passenger bus type, which is constantly stopping and restarting, speed of acceleration is of great importance, tending to considerably increase the mean speed of the vehicle without any increase of the maximum speed. Increased acceleration, if common to all vehicles, would speed up the traffic rate of the streets generally, and thus increase their carrying capacity.

The fact alone that gear changing was the exception and not the rule, as at present, would, in itself, tend to an improved service due to less fatigue to the driver, and would, in fact, largely reproduce with internal-combustion engines the almost ideal conditions obtained in this connection with steam.

If the foregoing be true with reference to road transport it is certainly also true with regard to transport on rail, such as yard shunting locomotives, etc. Such engines are, of course, almost continually employed starting up heavy loads from rest, so that the benefits derived from a large starting torque should be felt in a peculiar degree.

On the whole, the writer shows that for certain work the supercharging engine may possess three advantages: namely, lower fuel consumption under working conditions; greater torque at starting and at reduced speed; and greater horsepower for its cubic capacity, of which the last is hardly worth while with the exception of the semi-Diesel type of engine. (*The Automobile Engineer*, vol. 11, no. 155, Oct. 1921, pp. 337–341, 2 figs., *gtA*)

MACHINE DESIGN AND PARTS

Riveted Joints. Butt joints usually carry two rows of rivets, but a joint devised in England (Fig. 4), in particular for joining

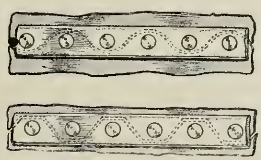

Fig. 4 Butt Joint with a Single Row of Rivets

panels of motor bodies, is of the butt type but so arranged that only a single row of rivets is required for it.

This result is obtained by scalloping the abutting edges of the plates so that the projection thus formed upon the one plate can be located in the corresponding notches formed on the other plate.

The rivets are therefore in a straight line and adjacent rivets lie alternately in each plate, being located in their respective projecting parts. Various forms of scalloping may be adopted, two kinds being shown in the illustration. (*Motor Transport*, vol. 33, no. 865, Sept. 26, 1921, p. 345, 1 fig., *d*)

MARINE ENGINEERING (See also Measuring Instruments)

Abandonment of Turbine Electric Drive by a Swedish Company. It is stated that the Ljungstrom Steam Turbine Co., electric transmission, has recently abandoned the electric drive and installed mechanical friction clutches with friction disks for reversing and power transmission. (*Motorship*, vol. 6, no. 10, Oct. 1921, p. 819, *g*)

MEASURING INSTRUMENTS

Thrust Meters in Marine Work. General discussion of the subject of thrust meters and the results which may be obtained thereby, based on tests on the British destroyer *Mackay* and the U. S. destroyer *Pruitt*.

In both cases the operation of the meters enabled a measurement of thrust over a range of speed to be obtained, which, by its ease of application and reliability of results, offers a method of solution of many problems connected with both resistance and propulsion which for lack of such apparatus have hitherto defied precise analysis.

The two performances essentially corroborate one another to a very marked extent. Among other things, thrust meters show precisely what the propeller is doing (whether cavitation is present or not), and by deduction from the effective horsepower of the model permit assessing the uncertain influences of air or appendage resistance.

When cavitation is present accurate calculation of the thrust horsepower delivered by the screws becomes very difficult. The use of the thrust meter largely discounts this uncertainty of results. As an instance may be cited the fact that the measured thrust per square inch of projected area of screws ran up to 15.7 lb. in the case of the *Pruitt* and to just 15.0 lb. in the *Mackay*, but though the *Mackay's* propellers were obviously breaking down, the *Pruitt's* were still continuing work with high efficiency. Calculated from the effective horsepower of the model with appendages the respective pressures were 14.8 lb. and 12.5 lb., which is but a small instance of the light shed on some unsolved propeller problems by this measurement.

Thrust measurements will not solve the problem of the propeller efficiency of the ship, but they remove a most important element of doubt regarding its performance. The determination of the wake factor in the ship as distinct from the amount found by experiment in the tank, is essential before the real slip, and hence the efficiency, can be accurately estimated. This can be best done when the true thrust is known.

But it is mainly in the facilities which it affords for the comparison of experimental data with observations in practice that the value of the thrust meter will be found. It possesses the paramount advantage of giving the actual resistance of the whole ship under any condition or combination of conditions of loading, trim, weather, state of sea, depth of water, or condition of bottom; quite apart from the comparative data to be gained regarding the differences between trial and service performance, such matters as astern performance or maneuvering data (one engine ahead and the other astern) can be elucidated, while the use of actual screws to corroborate model results for purposes of design can now be placed on a very definite footing. In these items there is scope for a deal of research and profitable development of knowledge. (*The Engineer*, vol. 132, no. 3432, Oct. 7, 1921, pp. 375–376, (editorial), *g*)

MOTOR-CAR ENGINEERING

Unconventional Italian Tractor

The Agrophile Tractor. Description of a new type of Italian tractor (the Pavesi) of unconventional design.

It consists of two separate carriages whose wheels are controlled and united or separated as required. Each carriage consists of a frame ending on one side in an arched rod shaped like a convex arc and fitted on the under part with a rack. The engine (horizontal, opposed, two-cylinder), steering gear and gear box are in the forecarriage, while the differential is in the second carriage.

To assemble the two carriages they are joined by the arched parts, which thus have a similar function to that of the buffers on tramway trailers, and they are fixed by means of a jointed cardan tie rod on the two axles. This tie rod carries, at its center,

a loose pulley which engages with the two racks placed below the curved members. Another shaft with a double cardan goes from the gear box of the main carriage and controls the differential of the second carriage. The four wheels are all driving as well as steering wheels, or, more accurately speaking, two axles steer. In fact, if the driver moves the steering wheel, the axle E of the main carriage AV (Fig. 5) turns obliquely, e.g., to the left of E_1, which moves the curved members to the right. The rack c carries the loose pinion p of the tie rod T, but this, on turning, forces the rack c' and the curved member of the second carriage AR to move to the right, and, consequently, forces the axle E' of that carriage to move to the right and take up the position E'_1. The two axles are then in such a position that a very short radius is required for turning the tractor. In fact, the external turning radius is 3.25 m.

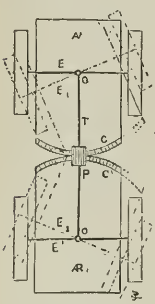

Fig. 5 Agrophile Pavesi Tractor

When it is observed that the articulations o and o' of the tie rod T on the two axles are cardans, it will be seen that the two carriages can take up any position in a transverse direction compared with each other. Thus the tractor can travel on the most uneven ground, as its two driving axles allow it to overcome obstacles more easily in spite of an average power and relatively light weight (2350 kg.). The usual compensation for complicated transmissions requires total adherence, and the complication is partly avoided in this case by the use of driving and steering axles instead of driving and steering wheels.

For light work, the driving carriage can be used alone by attaching it to a cart as a forecarriage; but with both carriages the high tractive effort obtained is sufficient to tow several vehicles (*The Practical Engineer*, vol. 64, no. 1806, October 6, 1921, p. 218, 1 fig., *d*)

POWER-PLANT ENGINEERING (See also Special Processes)

High Steam-Pressure Economies

Economy of Steam Engines, Frederick Samuelson. Discussion of high steam pressure and other means of increasing economy of steam engines.

In all heat engines the theoretical efficiency depends upon the limiting temperatures between which the plant works. In steam engines the lower limit of temperature is determined by the condenser, and to obtain a higher efficiency it is necessary to raise the upper limit of temperature, either by superheating the steam, or raising its pressure, or both.

The ideal efficiencies obtainable, that is, the values of the ratio: (heat available in steam)/(total heat in steam), corresponding to various pressures and temperatures in the simple steam turbine, are shown in Fig. 6. As the highest safe working temperature when ordinary materials of construction are used is about 800 deg. fahr., higher efficiencies can only be obtained by increasing the pressure.

The steam consumptions of a larger turbo-generator set under various conditions are shown in a table. The figures do not include auxiliaries, and assume a boiler efficiency of 100 per cent. With 350 lb. pressure, 300 deg. fahr. superheat, 29 in. vacuum, and cold feed, the consumption is 9.60 lb., and the efficiency 26.38 per cent. With feedwater raised to 300 deg. fahr. by steam extracted from the turbine, other conditions remaining as before, the steam consumption increases to 10.72 lb.; but the overall efficiency is raised to 28.44, or an improvement of over 7.5 per cent.

When evaporators are necessary, they should be heated by steam abstracted from the turbine, and the water evaporated should be condensed in the feedwater. With feedwater at 300 deg. fahr. stack losses should be kept down by inserting an air heater after the usual economizer.

A 1500-kw. plant constructed by the author's firm (British Thomson-Houston Co.) and supplied with steam at 350 lb. superheated to a total temperature of 700 deg. fahr., has been in use since 1914. It has proved very successful, and the expected saving in coal of 15 to 18 per cent has been more than realized. Larger sets of from 5000 to 15,000 kw., to work under similar steam conditions, are now being supplied. (*Proceedings of the Institution of Mechanical Engineers*, no. 6, Oct. 1921, pp. 601–604 and discussion pp. 604–606, 2 figs., in original article, *gp*)

Steam-Condenser Design and Construction

The Modern Steam Condenser, E. R. Briggs. A general discussion of condensers with particular regard to the practice of a certain British manufacturing company. Only certain parts are abstracted here.

The author is not in favor of the so-called "boat-shaped" condenser, claiming that it is unsatisfactory in that it requires internal stays which interfere with the flow of the steam, and is moreover expensive to construct.

As regards the method of withdrawing the air from the condenser without permitting air pockets, the article describes and illustrates an arrangement where the air branch is taken from the side of the condenser and communicates with the space inside the plate that extends the whole length of the body. As regards the permissible amount of air in a condenser, it is stated that from 3 to 6 lb. of air per 10,000 lb. of steam is allowed, the higher figure for 3000-kw. sets and the smaller figure for 20,000-kw. sets. The method of basing the air allowance on the quantity of the steam is very unsatisfactory, because only a very small amount of the air to be dealt with comes over with the steam itself, the bulk

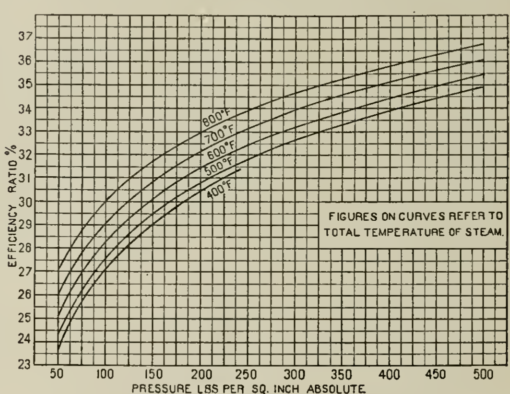

Fig. 6 Efficiencies in Steam Turbines at Various Steam Pressures

of it entering through the turbine glands and the joints in the exhaust piece and condenser. An excess of air can usually be detected by noting the difference between the temperature of the condensate in the bottom of the condenser and the actual vacuum, the original article giving the complete calculations necessary.

In Great Britain the transportation factor enters into the design of a condenser to a very serious extent, because of the limitations of the British loading gage. Generally speaking, condensers up to 8 ft. internal diameter can be fitted with tips at the maker's works and so delivered to site. Above 9 ft. diameter it is seldom possible to deliver the shell in one piece. Up to 11.5 ft. the shell can be made in rings, but above 11.5 ft. the body and water boxes must be divided into segments, which means, as a matter of fact that the segmental type must be used for practically all units in excess of 20,000 kw.

A typical British condenser design is described and illustrated in the original article. The tubes are of Admiralty mixture, $^3/_4$-in. O.D. by 18 gage. In some of the condensers, instead of following the usual practice in the arrangement of the inlet and outlet water boxes, the arrangement shown in Fig. 7 was employed. This arrangement permits of easy stream-line flow of the water from the pipe line (40 in. diameter) into the tubes and from the tubes to the return pipe. The frictional resistance required to get the water into and out of the condenser is reduced, which means

(*English Electric Journal*, vol. 1, no. 6, April 1921, pp. 244–253, 9 figs., *d*)

RAILROAD ENGINEERING (See also Transportation)

Feedwater Heating on the London and Northwestern Railway. Details of the latest application of the Weir feedwater heating system and pump to a George V.-class express locomotive. This arrangement is different in some respects from that previously used. Thus, the pump is placed alongside the front of the smokebox on the left-hand side of the engine, and a top feed device is used mounted on the boiler barrel between the steam dome and the safety valves. The feed device consists of a spray delivery valve through which the hot water passes into the boiler.

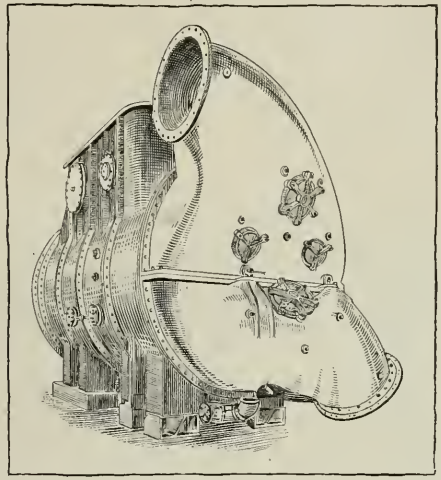

Fig. 7 End View of a British-Built Condenser, Showing Inlet and Outlet Water Boxes

The pump is of the vertical double-acting type essentially similar to the Weir marine boiler feed pump. Its principal feature is the method of distributing steam to the cylinder whereby the pump will work well at all speeds from as slow as one stroke in 5 min. up to about 30 double strokes.

G. and J. Weir, Ltd., the makers of this device, are the strongest advocates of direct-contact feed heating for marine work, but adhere to the surface type in their locomotive work.

This is due to the belief that the direct-contact heater is inherently weak, owing to the complication of the feeding agents, and would have to be too large to fit on a locomotive or its necessary feeding agents too small for their work. Because of this a heater is used of the surface type, consisting of a cast-iron shell with end doors and a tube element made up of straight, solid, drawn copper tubes expanded into headers, one of which forms the end cover of the shell while the other is free to move within the shell due to the expansion or contraction of the tubes.

In the heater installed on the locomotive described here, the water traverses the element 12 times by means of two tubes each flow, the headers being divided into compartments. The provision of these divisions within one casting eliminates the objectionable necessity of having joints under high pressure. (*The Railway Gazette*, vol. 35, no. 16, Oct. 14, 1921, pp. 572–574, 2 figs., *d*)

REFRIGERATING ENGINEERING

High-Speed Ammonia Compressor

High-Speed Ammonia Compressor. Description of a compressor of British manufacture having a normal running speed of 350 r.p.m. and cylinders with an internal diameter of 9 in. and piston stroke of 9 in.

day and an ice-making capacity of 60 tons a day of 24 hours. It is of interest to note that the definition of capacity adopted by the British manufacturers is the standard definition of the American Society of Refrigerating Engineers (December, 1920) which, it is said, will probably be adopted universally in England in the near future.

The advantages from the employment of the high-speed compressors are reduction in weight, space occupied, and first cost. In this case the actual floor space required by the steam-driven plant is 85 sq. ft., whereas that for a horizontal slow-speed compressor of similar capacity driven from the tail rod of a steam engine would be about 385 sq. ft. The weight of the compressor and the bed plate alone is $7^1/_2$ tons, or about one-third of the weight of a slow-speed horizontal machine of equal capacity.

The compressor is of the four-cylinder vertical single-acting type with a totally enclosed crankcase and forced lubrication.

The crankcase is of the dry type, the used oil passing through an opening into a large tube situated between the crankcase and bedplate. From this tube it is drawn through a strainer by means of a gear-type rotary pump and delivered through jets to the main bearings and stuffing boxes. Other jets in the delivery pipe supply oil to the big ends, gudgeon pins and cylinder walls.

The cylinders and pistons are all of the same construction, a fact which together with the sectional construction of the crankcase considerably reduces the time and cost of manufacture. Also machines of different capacity can be made up by merely employing a larger or smaller number of cylinders.

The upper portion of the cylinder is bored to a larger diameter than the working portion, and in it fits a movable head which is held in position by three strong helical springs in compression. The lower ends of these springs fit into recesses in the head, and their upper ends are pressed downward by a cast-iron dished cover secured to the cylinder casting by means of studs. It will be readily understood that this arrangement constitutes a safety device, which serves to relieve excess of pressure arising from any accidental cause, and also to prevent any serious damage from occurring in the event of a solid foreign body getting into the cylinder. The head itself, which is shown to a larger scale in Fig. 8 is composed of two steel forgings, of which the lower one forms the seat for the delivery valves. The lower part, it will be seen, is formed with a screwed shank, and a nut on this clamps the two parts together. Two annular valves, made of a specially hard and tough steel alloy, are provided, and these valves, which are formed with lips on their working faces, cover the delivery ports in the lower portion of the cylinder head. The valves are prevented from moving laterally by three resilient stops, one of which is shown in section on the left of Fig. 8, and their vertical lift is controlled by light steel springs surrounding the stops, as will be clear from the illustration. The necessary lift for normal working conditions is of the order of $^1/_{16}$ in., and vertical movement in excess of this amount is limited to the resilient stops. The compressed gas passes through the annular delivery passage to a pipe connection and it should, perhaps, be explained that the smaller annular groove above the delivery passage is provided merely to reduce the thickness of the metal at this part; it has no connection with the working of the compressor.

The inlet arrangement is one of the most interesting features of the design. Four annular inlet valves, of similar design and material to the delivery valves above described, are fitted, and their lift is restricted by spring-controlled bolts, as will be clear from Fig. 8. The heads of these bolts are formed with flanges which project over two valves, as shown, but parts of the flange are cut away, so that by pulling up the bolts against the action of the springs and turning them about their axes, the valves can be removed for examination without withdrawing the piston; snugs on the heads of the bolts prevent them from turning in their normal working positions. The opening and closing of the inlet valves is produced mainly as a result of inertia effects, as will be clear from the consideration of the motion of the piston. When the latter commences its down stroke, assuming for simplicity that the motion is simple harmonic, the downward acceleration will be a maximum, so that the valves will leave their seats and allow the gas to pass into the space above the piston. The ac-

celeration, of course, diminishes as the piston descends, becoming zero in the middle of the stroke and afterwards changing sign, so that the valves then tend to return to their seats. The difference in pressure is, however, sufficient to prevent them from doing so until the retardation reaches its maximum value at the end of the down stroke. On the up stroke the conditions are of course reversed, inertia effects at first assisting in keeping the valves closed and afterwards tending to open them, but before this latter stage has been reached, the gas pressure above the piston has risen sufficiently to counteract the effects of inertia.

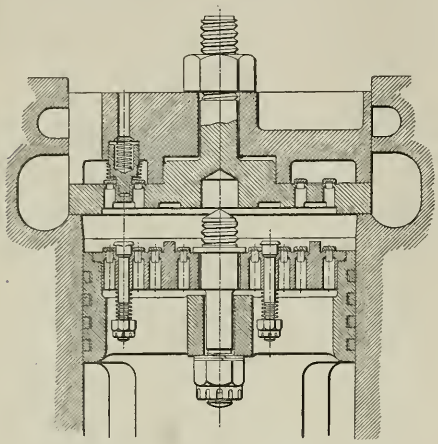

Fig. 8 Head of High-Speed Ammonia Compressor

From the foregoing descriptive matter it will be seen that the inlet and delivery arrangements of the machine are designed in accordance with the well-known uniflow principle, and it is perhaps hardly necessary to point out that the arrangement has similar thermodynamic advantages in the case of an ammonia compressor to those experienced in the working of a uniflow steam engine. The fact that the inlet and delivery passages are widely separated, greatly reduces the interchange of heat between the fluid and the metal, thereby diminishing the superheating of the incoming gas. The larger passages and valve openings, rendered possible by the annular valves, also have the effect of reducing wiredrawing, and these two features together materially increase the volumetric efficiency of the machine and the weight of gas pumped, in comparison with the older double-acting compressors having mushroom valves. The large valve openings, as already mentioned, are obtained with a very small lift, and this fact, in conjunction with the light weight of the valves, eliminates hammering and reduces wear to almost negligible proportions; the largest inlet valve in the compressor illustrated, we may add, weighs only $2^1/_2$ oz. Another feature which should be mentioned in this connection, is that the inlet ports in the piston head are drilled obliquely with the axis, so that the gas flowing through them has a velocity component tangential to the valves. A slight rotary motion is thus imparted to the latter, which tends to dislodge any particles of grit present on the seating, and also to render the small amount of wear taking place quite uniform. (*Engineering*, vol. 112, no. 2910, Oct. 7, 1921, pp. 507–508 and 510, 9 figs., *dA*)

SPECIAL MACHINERY

Thrust-Boring Machines. Description of a new method and machinery for constructing underground public lines without disturbing the surface layer. This machine was used extensively during the war where pipes and cables had to be laid under roadway crossings and it was not possible to stop the traffic and dig a trench in the ordinary way. A similar purpose machine has also recently been used by the British Postoffice Department for thrusting nine $3^1/_2$-in. steel pipes under the Channel Sea River at Stratford, London.

In this instance the Manganol-Irving thrust-boring machine was used, consisting of a hydraulic ram and various accessories. The ram consists of a steel cylinder and piston and the cylinder, which is approximately 5 ft. long, is fitted in a substantial iron crane and provided with means for rotation.

The apparatus works only on ground of a clay nature and the hardest blue London clay can be thrust-bored; it is not suitable, however, for chalk, sand, rock, etc. Holes from 2 to 12 in. diameter and in some cases even larger sizes can be made. (*The Postoffice Electrical Engineers' Journal*, vol. 14, no. 3, October 1921, pp. 181–188, 19 figs., *dA*)

Self-Contained Tunneling Machine

Tunneling Machine. Description of a tunneling machine comprising a tunnel shield with a boring head and a rotating tail attachment, by means of which the lining is placed as the machine progresses.

One motor drives the boring head and the rotating helix. The head is movable, which makes it possible to change the direction or grade of the tunnel.

As the helix rotates it produces in the caterpillar tread an advancing gap for inserting the concrete lining blocks, one at each end around the bore. The blocks, which are of peculiar shape, are set in spiral courses, so that as the helix revolves it forces the shield ahead by screw action. The same thrusting action closes up the lining joints and expands the lining ring through the space occupied by the shell of the shield. Fig. 9 shows the machine in operation.

One of these machines is now operated in an experimental tunnel in Philadelphia, Pa. The tunnel is through schist and has a 5-ft. bore. (*Engineering News-Record*, vol. 87, no. 14, Oct. 6, 1921, pp. 555–556, 3 figs., *d*)

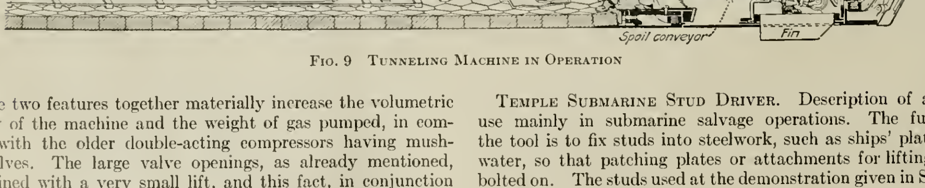

Fig. 9 Tunneling Machine in Operation

Temple Submarine Stud Driver. Description of a tool for use mainly in submarine salvage operations. The function of the tool is to fix studs into steelwork, such as ships' plates, under water, so that patching plates or attachments for lifting may be bolted on. The studs used at the demonstration given in September in London were of a tool steel tempered to a dark blue color, with one end bluntly pointed, after the manner of the old pattern of service projectile, and the other end having a screw thread cut on it.

The studs were about $3^1/_2$ in. long and $^5/_8$ in. in diameter. They were shot into a $^9/_{16}$-in. steel plate from the muzzle of a "gun," held in contact with the plate and pierced the latter so that about an equal length of the stud was left projecting on both sides.

and exit, the stud appearing quite uninjured. The operation of driving the stud was instantaneous and the noise hardly more than that of an air gun.

The Temple gun resembles a pneumatic hammer, but with the handle crosswise at the end like that of a spade. Pressure of the muzzle of the gun against the work causes the barrel to telescope slightly against the action of a spring, which causes a striking pin to detonate the cap and fire the explosive charge. The charge, which may consist of any ordinary propellant explosive, is contained in a cylindrical metal cup attached to the rear of the stud. (*Engineering*, vol. 112, no. 2909, Sept. 30, 1921, pp. 475, *d*)

SPECIAL PROCESSES (See also Fuels and Firing)

Hammer Welding

Hammer-Welding Plant of the Blaw-Knox Co., Ernest Edgar Thum. Description of the process used at the plant, of interest because of the fact that comparatively little information is available on hammer welding.

At the Blaw-Knox Co. tanks of various kinds are produced by this method, such as dephlegmators, stills for cracking gasoline, etc. In particular, the manufacture of a boiler shell, say, 8 ft. in diameter by 15 ft. long, is described. In the first place, a square plate of appropriate size is selected and the edges brushed vigorously with a wire brush to remove dirt or loose dust. The plate is then rolled into a cylindrical tube of correct diameter so that the edges overlap a distance about the thickness of the plate. As it is impossible to effect an exact closure of a long seam in the rolls, the plates are permitted to lap over each other in a blunt angle. Such a seam may often be welded immediately, especially if the bent plate is stiff enough so that there is little tendency for the two edges to spring apart when they are hammered. Shorter seams, heads and smaller fixtures are attached by screw clamps and "tacked" on with an oxy-acetylene flame, which means that the workman builds up short fillet welds at intervals of 3 or 4 ft.

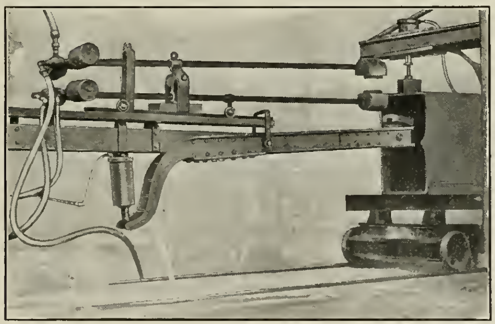

Fig. 10 Blaw-Knox Heating and Hammering Machine for Hammer Welding

A heating and hammering machine which is brought to the work consists essentially of two pivoted hammers (Fig. 10) carrying burners, another with an anvil, and a fourth may carry the air hammer, which may, however, also be held by a jib crane.

About five minutes is required to reach a welding heat on a 12-in. seam in $^7/_8$-in. plate. Fine sand or borax may be used as a flux, but if the flame is held with the slight deficiency of air, little trouble from slag or oxide is to be expected in low-carbon metal. When the proper temperature has been reached the gas and air are turned off, the burners swung to one side and their places immediately taken by the anvil beneath and the hammer above.

First light blows of the hammer are directed at the corner of the sheet, gradually working across the weld, ejecting any molten material in a sheet of white-hot sparks. High-speed blows at full air pressure are continued until the temperature has fallen to a faint red, when the force of the blow is lightened, but continued down the recalescence temperature to a black heat. The hammer this operation; the pipe meanwhile resting solidly on the horn, inertia in the hammer cylinder and arm absorbing the reaction from the blow. Air at 100 lb. per sq. in. is the motive power; the cylinder is 5 in. in diameter, the stroke is 11 in.; and a blow is struck 160 times per minute.

About half the length heated is welded in this operation, but in thick plate the region must be reheated and hammered twice more before the combined sheets are worked down to the thickness of the rest of the shell. This produces a lap joint which is at least 3 in. long in any sheet thicker than $^3/_8$ in. Flux is more liberally used in the second and third heatings. When this spot is finally joined to the foreman's satisfaction, the carriage is shifted and the same cycle of operations repeated on the continuation of the seam.

After the completion of welding the cylinder is replaced in the bending rolls. They are adjusted to give the exact curvature required and the seam rolled back and forth several times to bring this portion to correct shape. Water gas is used as a fuel. Good facilities are available for testing the welds. Among them is a long testing press for proving open-ended pipe up to 6 ft. in diameter and 40 ft. long at any pressure under 1500 lb. per sq. in. After a pressure of 50 to 100 per cent in excess of the working load has been supplied, the seam is struck vigorously several times with a 10-lb. sledge. This not only lays bare many a defect which would not be detected by a static load, but actually subjects the whole structure to a considerable impact as is evident by the pressure gage jumping about 100 lb. at each blow. It is important to note that such testing should never strain the vessel much more than 80 per cent of the proportional limit of the material, as otherwise the metal will become somewhat brittle due to cold work. (*Chemical and Metallurgical Engineering*, vol. 25, no. 16, Oct. 19, 1921, pp. 747–751, 8 figs., *d*)

Oil Cooling

Cooling Oil From Quenching Tanks, S. E. Derby. An article dealing chiefly with cooling the oil used in quenching steel, but in some of its parts applicable also to the general problem of cooling oil, such as that coming from the bearings of machinery.

In particular reference to the question of steel treatment, it is noted that proper speed of cooling is a determining factor in the degree of hardness attained in the steel. The rate of cooling depends primarily upon the size of the piece of metal, but also upon the composition of steel and the rapidity with which the cooling or quenching medium removes the heat. This rapidity is determined by the nature of the medium, its fluidity, specific heat and temperature. Because of this, oil in quenching tanks must be maintained at a certain temperature suitable for each particular kind of operation, and this means that the oil must be recooled.

Modern practice favors recooling by circulating the oil in a closed circuit and recooling it in a separate cooler. The original article describes some typical oil coolers.

Data presented in the original article show that the quenching speed varies considerably with the oil used and initial temperature of the bath. Thus G. W. Pressell found the figures given in Table 1.

The variation in temperatures as apparent from Table 1 indicates the importance of the proper system of oil recooling.

TABLE 1 QUENCHING SPEEDS OF OILS AT DIFFERENT INITIAL TEMPERATURES

Kind of Oil	Variation of quenching-bath temperatures	Variation in time required for the steel to cool from 1200 to 600 deg. fahr.
Fish oil, lot no. 1	88 to 255	97 to 120
Fish oil, lot no. 2	71 to 251	78 to 93
Linseed oil	84 to 261	94 to 107
Cottonseed oil	100 to 230	104 to 119
Heavy viscous drawing oil	75 to 229	154 to 181
Houghton's no. 2 soluble quenching oil	82 to 249	97 to 102

Fig. 11 (page 820) shows the ratio of water to oil for a typical oil cooler and another figure in the original article gives the heat-transfer rate with viscosity corrections for an oil cooler.

The general practice is to specify one gallon of oil for every pound of steel quenched per hour, and the original article gives practical methods for determining the size of cooler necessary and the quantity of circulating water. (*Forging and Heat Treating*, vol. 7, no. 10, pp. 528–530, 6 figs., *dg*)

Recent Improvements in the Manufacture of Welded Pipe, F. N. Speller, Mem. Am.Soc.M.E. After a general statement of the history of the manufacture of butt-welded pipe beginning with the work James Russell in England in 1824 and carried down to the Spellerizing process of recent years, the author proceeds to the discussion of the most modern method of scale removal.

Mill scale on butt-welded steel piping is of a peculiar character. It consists essentially of iron oxides, principally Fe_3O_4, with 7 or 8 per cent of silica and smaller amounts of C_2O and Al_2O_3 from the furnace bottom. At the welding temperature this scale is fluid and forms a natural flux for welding, as well as a protection to the metal against excessive oxidation from the furnace gases, so that this is a very essential factor in the welding of pipe—so much so that pipe steel is made primarily so that it will be self-fluxing by readily forming this fluid oxide at as low a temperature as possible. Wrought iron carries considerable excess of fusible slag and oxides intermixed with the metal, whereas pipe steel when properly made readily forms a suitable fluxing scale when heated to the welding temperature. The melting of the welding scale affords the welder a sharp indication of the temperature of the skelp, which is much better than any pyrometer for this purpose. On cooling, the welding scale passes through a viscous stage and then quickly becomes brittle at a temperature at which the steel is still quite easy to forge. Most of the scale on the outside is removed in the sizing and straightening rolls, but inside the pipe scale is often $^1/_{32}$ or $^1/_{16}$ in. thick in patches, and when cold is firmly attached to the metal like an enamel. Several means have been used to remove this scale to prepare the pipe for galvanizing and other coating operations. Pickling in acid is the most common

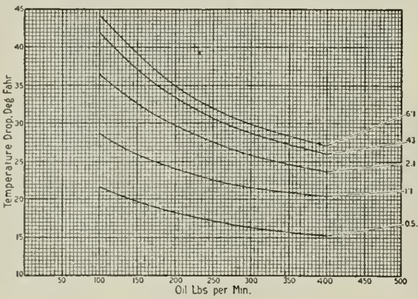

Fig. 11 Water-to-Oil Ratios for a Typical Oil Cooler

method employed but is the least effective on the inside of pipe where the scale is most firmly attached, and, further, as the scale is very irregular and rather thick in spots, portions of the metal are likely to be damaged by overpickling before all the metal is cleaned. Mechanical cleaning by sand blasting and cold rolling has been tried, but has not been thorough enough, besides being quite costly.

By making the diameter of the pipe larger and then reducing the size and elongating the pipe at the highest temperature at which the scale is brittle enough to remove, it has been found possible to clean the pipe in the process of hot finishing and at the same time produce a better material in other respects. This new process of finishing is very advantageous. It will be seen that two additional steps are introduced in the finishing operation in order to produce what is practically a scale-free pipe: (1) a partial cooling from about 2500 deg. to 1800 deg. fahr.; and (2) a reduction in diameter and elongation of about 10 per cent in length by means of a series of horizontal and vertical rolls, by which the brittle scale is cracked and separated from the steel. The pipe is then straightened and cooled as usual, during which a thin film of new oxide forms sufficient to protect the metal from rusting while being handled. A thin coating of suitable lacquer is now applied, which affords substantial protection to the pipe in storage. The main object of these scale-removing and cleaning operations is to make possible more uniform galvanizing. This also has an important bearing on the manufacture of all kinds of coated pipe and conduit for electrical purposes. (*The Blast Furnace and Steel Plant*, vol. 9, no. 10, October 1921, pp. 580–582, *d.* In connection with this article attention is called to a paper by the same author on Control of Corrosion in Iron and Steel Pipe, published in Mechanical Engineering, Oct. 1921, p. 661 et seq.)

THERMODYNAMICS

A New Thermal Testing Plate for Conduction and Surface Transmission, F. C. Houghton and A. J. Wood, Mem. Am.Soc. M.E. Summary of an investigation conducted jointly by the Engineering Experiment Station of the Pennsylvania State College and the Research Laboratory of the American Society of Heating and Ventilating Engineers at the thermal testing plant of the Pennsylvania State College.

Essentially the heating plate is similar to that used by the U. S. Bureau of Standards, with the difference, however, that in the plate employed at the Pennsylvania State College one side of the blank is exposed to the air in a cold room which is kept at a uniform temperature. This makes the plate method adaptable only when the room temperature can be controlled, but it permits determining at the same time both conductivity and surface transmission constants.

The plate is heated by an electric heating element, while the cold room is maintained at the proper temperature by brine circulation. The original article gives the methods of calculations and results of tests with temperature differences ranging from 52.4 to 71.5 deg. fahr., as well as the errors occurring in these measurements. (*Journal of the American Society of Heating and Ventilating Engineers*, vol. 27, no. 5, July 1921, pp. 529–542, 12 figs., *e;* also *Journal of the American Society of Refrigerating Engineers*, vol. 8, no. 1, July 1921, pp. 23–36, 12 figs., *e*)

TRANSPORTATION

Pipe-Line Transportation for Anthracite and Bituminous Coal, Geo. A. Orrok and W. S. Morrison, Members Am.Soc.M.E. Discussion of a plan of pumping coal from the coal fields to New York, with data as to the cost of plant and operating costs.

The idea is not new and has been under consideration since the early nineties. Transportation of material in a more or less finely divided state by a stream of water has long been known and practiced, and, among other things, is the method used in handling the vast deposits of phosphate rock in Florida located mostly under water.

It is proposed to have from place to place relay stations with four separate single-stage pumping units at each. The units are to be direct-connected, each to its own motor and arranged to operate in pairs in series with each other, with the discharge from the first pump taking its supply from the supply connected to the suction of the second and the discharge from the second delivering into the line main.

Three routes have been tentatively laid out: one from Scranton to Piermont on the Hudson, 130 miles; (2) from Scranton to Newark Meadows, 195 miles; (3) from Clearfield to Piermont, via Scranton, 322 miles.

The estimated cost of the plant varies from $12,100,000 for Route 1 to $31,830,000 for Route 3. The fixed charges and operating expenses together vary per ton from 62.8 cents for Route 1 to $1.47 for Route 3.

A 14-in. pipe line can handle an average of 6,000,000 tons of coal per year and three such lines would probably provide for the entire New York supply of both anthracite and bituminous coal.

In this estimate the cost of the necessary water is not included, though in some cases it might become an important item. It is not believed that there will be any material trouble in the corrosion of pipes resulting from sulphur content in the coal. (Address before the Association of Edison Illuminating Companies, Spring Lake, N. J., Sept. 12, 1921, abstracted through *Power*, vol. 54, no. 18, Nov. 1, 1921, pp. 699–700, *d.* Attention is also called to a brief editorial in the same issue of *Power* on p. 688.)

WOODWORKING MACHINERY

Machine for Railway Tie Making

Cross-Cutting, Adzing and Boring Machine for Railway Ties. Description of a machine built by a British concern for

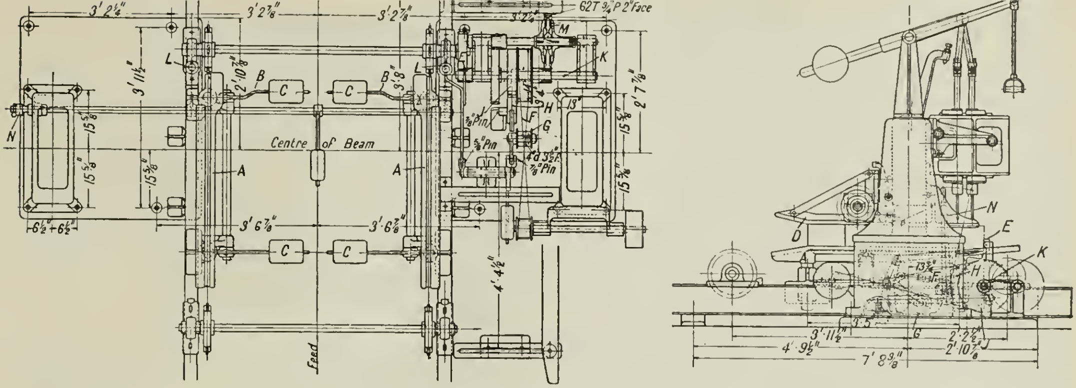

Fig. 12 Sleeper Cutting, Adzing and Boring Machine

the Indian State Railways designed for cross-cutting and boring ties up to 10 ft. long, 10 in. wide and 6 in. deep; it will also adz rail seatings up to 10 in. wide and 16 in. long. This machine is shown diagrammatically in Fig. 12, and the original article contains also two halftone views.

An interesting feature of the machine is the method employed to drive the boring spindles. For this purpose a series of four endless roller chains running in horizontal path are provided, each chain driving two spindles. The chains are of Renold's bush roller pattern. The gear box contains a pair of miter wheels running in an oil bath, the horizontal shaft being fitted with an outside driving pulley to receive motion by belt from the overhead countershaft. This type of drive was found convenient where universal adjustments of the spindles are necessary. (*The Engineer*, vol. 143, no. 3431, Sept. 30, 1921, pp. 348, 353–354, 3 figs., *d*)

CLASSIFICATION OF ARTICLES

Articles appearing in the Survey are classified as *c* comparative; *d* descriptive; *e* experimental; *g* general; *h* historical; *m* mathematical; *p* practical; *s* statistical; *t* theoretical. Articles of especial merit are rated *A* by the reviewer. Opinions expressed are those of the reviewer, not of the Society.

New Bolinder Engine

A notable improvement on the Bolinder semi-Diesel engine has been perfected, and one of these new engines fitted into a tugboat on the Thames, the boat being the largest motor tug in Great Britain. The improvement is in the ignition device and the fuel-injection apparatus. The new fuel injector, the use of compressed air for keeping the ignition bulb cool has been eliminated, the use of water for the same purpose having been discarded for some time. The new device consists essentially of a housing, injection nozzle, and a spindle, which is capable of adjustment from the starting platform. The device is fitted on top of the bulb, and it is possible to run the engine at full load with the ignition bulk so cool that it remains black. It is also possible to run the engine at light load indefinitely, the bulbs retaining sufficient heat for ignition. The ignition device, which is electrical, is mounted in a water-cooled housing, and by means of a sleeve can be projected into the ignition bulb or withdrawn as required. When it is withdrawn a valve on the sleeve seals the chamber containing the igniter, thus protecting it from the heat of combustion, and when it is pushed forward in the chamber for starting purposes, a valve on the other end of the sleeve closes the water-cooled housing. With this device starting from cold can be accomplished immediately, without the use of any lamps for warming the bulb. The makers claim that with the new fuel injection device the power is increased by 20 per cent. The new model is known as the N.E., and has been fitted in several vessels besides the one mentioned here. (*Marine Engineering of Canada,* vol. 11, no. 10, Oct. 1921, p. 21)

CODE ON DEFINITIONS AND VALUES

(*Continued from page 810*)

151 *Heat Input for Otto and Brayton Cycles* is expressed as

$$\text{B.t.u. per i.hp-hr. or b.hp-hr.} = \frac{2545}{E_o}$$

$$\text{B.t.u. per net kw-hr.} = \frac{3413}{E_o}$$

152 *Water Rate* of an engine, turbine, or complete steam plant is the pounds of steam at actual condition, per unit of output; it is to be corrected neither for moisture nor superheat.

153 *The Quality of Steam* or other vapor is specified in two ways: If the vapor is superheated, the quality is described by stating the number of degrees of superheat. If the vapor is wet, the quality is described by stating the dryness factor; for example, if steam contains $2^1/_2$ per cent of moisture, its dryness is 0.975.

Dry Steam, to which most steam conditions involving wet steam were formerly corrected, is that condition at which there is present no moisture and no superheat, and the heat content is that of the point of saturation. It is a condition which cannot be exactly realized commercially, and as the correction to dry steam has never been applied to superheated steam, it appears advisable to discontinue its use. This does not bar its employment, as a condition, together with a definite pressure (and back pressure or vacuum), for correcting guarantee tests to a common state.

154 *Fuel Rate*, for solid and liquid fuels, is defined as the pounds of fuel as fired, per unit of output per hour. For gaseous fuels it is defined as cubic feet of gas at 68 deg. fahr. and one atmosphere, per unit of output per hour. It should be qualified by reference to the unit of output.

155 *Drawbar Horsepower* is the product of the dynamometer pull in pounds at the drawbar, on level track, and the speed in feet per minute, divided by 33,000.

156 *One Ton-Mile* is defined as one short ton transported a horizontal distance of one mile; it is not a work unit. Similarly, one train-mile is defined as a complete train transported horizontally one mile. Both of these units are used in general data on performance in the Locomotive Code.

157 *Heat-Transmission Coefficient* is defined as the British thermal units transmitted per square foot of heating surface per degree mean temperature difference per hour.

158 *Cooling-Tower Efficiency* is expressed by the formula—

$$\text{Efficiency} = \frac{t_1 - t_2}{t_1 - t_w}$$

where t_1 = temperature of water before cooling
t_2 = temperature of water after cooling
t_w = temperature of wet bulb.

ENGINEERING RESEARCH

A Department Conducted by the Research Committee of the A.S.M.E.

Research Theses

THE Research Committee has received from Prof. W. R. Eckart of Stanford University the following suggestions and would like to receive the opinion of those using this section of MECHANICAL ENGINEERING regarding the advisability of following them. The Committee would appreciate communications from those interested in the work of the engineering schools regarding the possibility of following out this plan in their own institutions:

1 In general, theses as presented to the universities are not in printed form and are not available for distribution. As a rule they are typewritten and about five copies represent the limit of successful duplication. One of these copies is retained by the university as a record and is available for reference in the library, other copies are retained by the student-authors themselves, and the remainder are ordinarily presented to members of the faculty under whose direction the work was performed.

2 Announcements in the Research Section have brought forth many requests for copies or for information. In most cases these requests cannot be complied with owing to prohibitive costs and lack of facilities for reproduction.

3 The result is, therefore, that much valuable technical information which might otherwise be available is tied up in the archives of the universities.

4 To remedy this situation it is suggested that the universities require their graduate or advanced students, at the expense of the university or departments of the same, to present in each case an additional copy of their thesis, which, if considered of sufficient merit is to be forwarded to the Library of The American Society of Mechanical Engineers. A copy would then be available for reference there or for publication either as a whole or in abstract in MECHANICAL ENGINEERING, and all requests for information regarding the same or for copies in part or in whole could be handled directly by the Society at the usual price for such work.

Committee for Scientific and Industrial Research

The Sixth Annual Report of the Committee of the Privy Council for Scientific and Industrial Research for the year 1920–21 has just been issued. The report describes the activity of the Committee during the year, includes a list of the various associations of Great Britain and in Part II the question of national research and the development of research in and for the Empire is treated. Part III covers aided research, patents and publications of learned societies.

The report may be obtained for 1s. 2½d. from Imperial House, Kingsway, London, WC2.

A—RESEARCH RESULTS

The purpose of this section of Engineering Research is to give the origin of research information which has been completed, to give a résumé of research results with formulas or curves where such may be readily given, and to report results of non-extensive researches which, in the opinion of the investigators, do not warrant a paper.

Cement and Other Building Materials A14-21. FIRE TEST ON BUILDING COLUMNS. Technologic Paper 184 is devoted to Fire Tests on Building Columns. It is obtainable from the Superintendent of Documents at 75 cents per copy. The work was undertaken in coöperation with the Associated Factory Mutual Insurance Companies and the National Board of Underwriters. The column was placed in a gas-fired furnace and loaded to a safe working load. The loaded column was exposed to fire for a predetermined time, after which a hose stream was applied to the heated column. In other cases the column was heated. The columns were protected by various forms of fire-resisting materials and care was taken to duplicate actual building practice. Ninety-five fire tests were made and fifteen fire and water tests. The results of the tests are tabulated. Figures and diagrams are used to illustrate apparatus and results of the test. The results are summarized in terms of two-thirds of the average time in hours for the column under fire to have its strength reduced to failure. These periods varied from ten minutes for unprotected steel columns to 8 hours for columns covered with 4 in. of concrete made with fire-resistant aggregate and for reinforced columns made with the same aggregates. The series cover the range of current practice in structural-steel columns and the studies indicate that the results obtained are applicable to columns of various sizes. Bureau of Standards, Washington, D. C. Address S. W. Stratton, Director.

Cement and Other Building Materials A15-21. COOLING OF FRESH CONCRETE IN ZERO WEATHER. Bulletin 123 of the Engineering Experiment Station, University of Illinois, by Tokujiro Yoshida, is on the subject of Studies on Cooling of Fresh Concrete in Freezing Weather. The investigation discusses the apparatus used for measuring temperature; concrete materials; mixing of concrete; general features of the experiments; preparation of test specimens; phenomena of experiments; rise in temperature during setting; calculation of the thermal constants of fresh concrete; effect of wood forms in protecting fresh concrete; effect of canvas in protecting fresh concrete; effect of amount of water used and summary of experimental results. This is followed by an analytical application to massive concrete, thin walls, beams and columns of rectangular and circular cross-sections, as well as some applications to work of concreting in freezing weather. The general conclusions are given as follows:

It is believed that the constants derived from the tests are applicable to the ordinary conditions of fresh concrete. The value of k, the diffusivity, is 0.0063; that of h, the ratio of the emissivity to the coefficient of conductivity, is 0.046.

From the cooling curves given for massive concrete, thin walls and slabs, and beams and columns, the time of cooling and the temperature attained by the concrete in any particular case may be estimated.

The protection afforded by board forms and by canvas is considerable, as was shown by the examples given.

If a canvas protection is used, care must be taken to prevent any circulation of cold air, and it is best to observe the temperature in the air space by means of a thermometer. Knowing this temperature, the time when the freezing temperature will penetrate into the concrete may be estimated from the diagrams and the necessity of using artificial heat determined.

The heating of the materials is seen to furnish an excellent method of insuring early hardening and delaying the fall in temperature. It is much to be preferred to the use of chemicals.

The effect of the wind should also be given consideration.

The diagrams are of some value in connection with the determination of the time for the removal of the forms, since they will enable the temperature attained by the concrete to be estimated. As the concrete gains strength much more slowly at a low temperature, and as frozen concrete is especially dangerous, information on the temperature attained is of value and the too early removal of forms may be avoided. If by this or other means the mean temperature of the concrete for a given time is known, the comparative strength of the concrete may be estimated from the diagrams given by Prof. A. B. McDaniel in Bulletin 81 of the Engineering Experiment Station of the University of Illinois, which shows the influence of temperature on the strength of concrete, and thus the judgment may be aided in deciding on the safe time to remove the forms. Address Dean C. R. Richards, University of Illinois, Urbana, Ill.

Fire Prevention A2-21. SPECIFICATIONS FOR FIRE HOSE. Circular 114 of the Bureau of Standards is devoted to specifications for fire hose. Specification was made to the Rubber Association of America and had received the official endorsement of its Committee on Technical Specifications. The specification covers cotton-lined hose of single, double- and triple-jacketed types. The chemical and physical tests to which hose must conform are described in detail. Bureau of Standards, Washington, D. C. Address S. W. Stratton, Director.

Fuel Utilization A1-21. ATMOSPHERIC BURNERS. The Bureau of Standards has recently published Technologic Paper 193 on Design of Atmospheric Gas Burners. This may be obtained from the Superintendent of Documents, Washington, D. C. This paper does not give any presentation of theory, but it does give the effects of various factors on the operation of burners. These are shown by means of tables and curves based on experimental data. To arrive at these results it was found necessary to study the theory of the flow of gas through different types of orifices, the principles governing the rate of injection of air into the burner, the design of the injecting tube, the rate of consumption of burners for different port areas and the effect of adjustment of the air shutter. The paper points out that the atmospheric burner is well adapted for domestic and small industrial purposes on account of its

Metallurgy and Metallography A18-21. Metallographic Testing. The second edition of Circular 42 of the Bureau of Standards on Metallographic Testing may be obtained from the Superintendent of Documents, Washington, D. C. Metallographic examination gives broader information of materials of engineering than the mere determination of mechanical properties. The circular describes briefly the conditions which effect the properties of metallic metals under the following headings: Microscopy and structure; thermal analysis and heat treatment; mechanical working of metals; chemical and metallurgical factors and conditions of melting. Bureau of Standards, Washington, D. C. Address S. W. Stratton, Director.

Petroleum, Asphalt and Wood Products A8-21. Buried Steel Fuel-Oil Tanks. The Associated Factory Mutual Fire Insurance Companies have recently determined data regarding the life of buried fuel-oil tanks. The investigation covered the study of tanks which had been in service from 18 months to 26 years and were buried from 10 in. to 9 ft. below ground level. The soils were of sand, gravel, loam, clay or cinders or mixtures of these. In some cases ground water was present and in few cases salt tidewater. The tanks varied in capacity from 1,100 to 22,000 gal. In a few instances the tanks were entirely uncovered in making the investigation, while in other cases a section only was exposed. This section included one side to the center line and one end to same point. The character of corrosion, condition and thickness of shell were noted, and in a few cases the scale was examined for analysis. The results of the investigation are given in the following table:

Number in Report	Age in years	Depth of top below ground	Protection and condition	Character of soil surrounding tank	Location of tank
1	1½	2 ft.	Red lead & asphalt Excellent	Salt marsh lower half, fill above	Everett, Mass.
2	7	2 ft.	Red lead	Clay, sand, trace of cinders	So. Boston, Mass.
9	10	2 ft.	Excellent		
3	7	5 ft.	Probably asphalt Fair	Clay, sand and cinders. Salt tidewater	New Bedford, Mass
4	7	7 ft.	Red lead & asphalt Excellent	Sand and gravel ground water	Waterbury, Conn.
5	8	3 ft.	Asphalt Good	Sand, loam and gravel	Lowell, Mass.
6	9	2 ft.	Probably asphalt Good	Sand, gravel and cinders.	Worcester, Mass.
7	9	3 ft.	Asphalt Fair	Sand, gravel, loam, cinders	Waltham, Mass.
8	10	4 ft.	Probably asphalt Good	Sand, loam, trace of cinders	Waterville, Conn.
10	11	7 ft.	Thick coat asphalt Excellent	Sand, gravel, few cinders	Waterbury, Conn.
11	11	4 ft.	Asphalt Good	Clay and sand	So. Auburn, R. I.
12	12	5 ft.	Asphalt Excellent	Oil-saturated sand. Salt tide water	New Bedford, Mass.
13	12	8 ft.	Concrete Good	Encased in concrete except at manhole. Ground water	Taunton, Mass.
14	13	2 ft.	Red lead asphalt Excellent	Sand and loam	Waterbury, Conn.
15	13	2 ft.	Red lead	Oily saturated sand and clay. Ground water	Lowell, Mass.
16	13	2 ft.	Good		
17	14	6 ft.	Probably asphalt Poor	Sand, gravel, cinders trace of oil. Ground water and acid	Waterbury, Conn.
18	15	2 ft.	Red lead Excellent	Black mud, formerly salt marsh. Ground water	Lynn, Mass.
19	15	9 ft.	Red lead & asphalt Excellent	Oily sand, brackish ground water	Taunton, Mass.
20	15	2 ft.	Asphalt Excellent	Clay, sand, trace of cinders	So. Boston, Mass.
21	16	3 ft.	Probably asphalt Good	Sand, cinders	Fitchburg, Mass.
22	17	5 ft.	None Fair	Sand, gravel, cinders	Pawtucket, R. I.
23 & 24	18	9 ft.	Red lead and tar Poor inside	Salt water, some cinders	Brooklyn, N. Y.
25	20	1 ft.	Red lead Excellent	Sand and gravel	Providence, R. I.
26	20	2 ft.	Asphalt Excellent	Loam, clay and cinders	Cambridge, Mass.
27	20	2 ft.	Probably none Good	Clay and sand Ground water	Whitins, Mass.
28	26	2 ft.	Red lead Good	Sand and gravel	Whitins, Mass.

The electrolytic theory of corrosion is the most acceptable one. Before iron can oxidize it must pass into solution liberating oxygen. Wet places with acids stimulate this. Corrosion will not take place without oxygen being present, hence tanks should be buried where conditions will not stimulate corrosion.

Fill. Cinders stimulate corrosion. Acid may be present in this soil. Loam is a better type of fill than cinders although it may stimulate filling. It is generally damp and prevents corrosion because it holds the water in a stagnant condition. Sand is the best filler as it prevents surface impurities from reaching the tank. Oily sand gives the best protection. Gravel is not quite as good as sand.

Protective Coating. Red lead when used alone allows contact between metal and corroding medium as film may be easily punctured. Asphalt when used alone also permits contact. Red lead followed by asphalt gives good results. All tanks reported in excellent condition were protected by red lead, asphalt or both. No tanks examined were entirely encased in concrete. It is reasonable to suppose that concrete would offer a good protection.

Tidewater and Ground Water. Tidewater and ground water do not stimulate corrosion to any great extent. Salt water usually forms a hard encrustation. Ground water acts similar but may stimulate corrosion when the oxygen content is great.

Depth of Bury. If a tank is buried below the zone of active oxygen it is usually below the zone of corrosion. As the depth of bury increases the tendency to corrode decreases.

Stray Electrical Currents. Stray electrical currents stimulate corrosion but these are not frequent.

Conclusions. Steel tanks buried under favorable conditions may last more than 30 years. In damp ground they will last from 15 to 20 years. To best resist corrosion steel tanks should be coated with red lead and asphalt buried in clean sand three feet deep or more below surface, avoiding ground water and tidewater if possible. Address Factory Mutual Laboratories, C. W. Mowry, Director, Boston, Mass.

Petroleum, Asphalt and Wood Products A9-21. Petroleum Laws. Petroleum laws of all America is the subject of Bulletin 206 of the Bureau of Mines. The work contains 645 pages and gives the national and state laws of the various countries. Address Bureau of Mines, Washington, D. C. H. Foster Bain, Director.

Petroleum, Asphalt and Wood Products A10-21. Sanitation. Oil-Camp Sanitation is the subject of Technical Paper 261 by C. P. Bowie. This bulletin of 32 pages discusses the construction of buildings and various conveniences and the matter of mosquitoes and flies, as well as the location of camps, spacing of buildings, water supply and disposal of garbage, sewage and refuse. Bureau of Mines, Washington, D. C. Address H. Foster Bain.

Properties of Engineering Materials A6-21. Manila Ropes. The Bureau of Standards has recently issued Technologic Paper 198 on Tests of Manila Rope. This may be obtained from the Superintendent of Documents, Washington, D. C. Ropes tested range from diameters of ½ in. to 4½ in. and consisted of commercial, three-strand, regular-lay ropes. The breaking load, weight per linear foot, number of yarns and the lay of the rope and strands as well as the elongation were measured. The average breaking load is given by the equation

$$L = cd\ (d + 1)$$

where L = load in pounds
c = constant = 500
d = diameter of rope in inches.

The modulus of elasticity was not constant. There is no well-defined elastic limit. The number of yarns in a rope is usually given by the equation

$$N = 50 \times d(d + 0.4)$$

where N = number of yarns
d = diameter of rope in inches.

Bureau of Standards, Washington, D. C. Address S. W. Stratton, Director.

B—Research in Progress

The purpose of this section of Engineering Research is to bring together those who are working on the same problem for coöperation or conference, to prevent unnecessary duplication of work and to inform the profession of the investigators who are engaged upon research problems. The addresses of these investigators are given for the purpose of correspondence.

Automotive Vehicles and Equipment B7-21. Equipment for Testing Automobile Brake Linings. The Bureau of Standards is developing apparatus for the purpose of testing brake linings. Blueprints of the apparatus have been sent to manufacturers of linings. It is hoped to standardize the method of testing this important product. Bureau of Standards, Washington, D. C. Address S. W. Stratton, Director.

Friction B1-21. Effect of Oil Grooves in Bearings of Varying Sizes and Speeds. This investigation is being carried on by Mr. Lessels, of the Mechanical Laboratory of the Carnegie Institute of Technology. Address David C. Saylor, Instructor, Mechanical Laboratory, Carnegie Institute of Technology, Schenley Park, Pittsburgh, Pa.

Heat B22-21. Heat Conductivity. An investigation on heat conductivity is being undertaken by Mr. Mawhinney in the Mechanical Laboratory of the Carnegie Institute of Technology. Address David C. Saylor, Instructor, Mechanical Laboratory, Carnegie Institute of Technology, Schenley Park, Pittsburgh, Pa.

Internal-Combustion Motors B10-21. Solid Injection of Fuel in Oil Engines. Solid injection of fuel oil is being investigated by Mr. Zeisham of the Carnegie Institute of Technology. Address David C. Saylor,

Instructor, Mechanical Laboratory, Carnegie Institute of Technology, Schenley Park, Pittsburgh, Pa.

C—Research Problems

The purpose of this section of Engineering Research is to bring together persons who desire coöperation in research work or to bring together those who have problems and no equipment with those who are equipped to carry on research. It is hoped that those desiring coöperation or aid will state problems for publication in this section.

D—Research Equipment

The purpose of this section of Engineering Research is to give in concise form notes regarding the equipment of laboratories for mutual information and for the purpose of informing the profession of the equipment in various laboratories so that persons desiring special investigations may know where such work may be done.

E—Research Personnel

The purpose of this section of Engineering Research is to give notes of a personal nature regarding the personnel of various laboratories, methods of procedure for commercial work or notes regarding the conduct of various laboratories.

F—Bibliographies

The purpose of this section of Engineering Research is to inform the profession of bibliographies which have been prepared. In general this work is done at the expense of the Society. Extensive bibliographies require the approval of the Research Committee. All bibliographies are loaned for a period of one month only. Additional copies are available, however, for periods of two weeks to members of the A.S.M.E. These bibliographies are on file at the office of the Society.

WORK OF THE A.S.M.E. BOILER CODE COMMITTEE

THE Boiler Code Committee meets monthly for the purpose of considering communications relative to the Boiler Code. Any one desiring information as to the application of the Code is requested to communicate with the Secretary of the Committee, Mr. C. W. Obert, 29 West 39th St., New York, N. Y.

The procedure of the Committee in handling the cases is as follows: All inquiries must be in written form before they are accepted for consideration. Copies are sent by the Secretary of the Committee to all of the members of the Committee. The interpretation, in the form of a reply, is then prepared by the Committee and passed upon at a regular meeting of the Committee. This interpretation is later submitted to the Council of the Society for approval, after which it is issued to the inquirer and simultaneously published in Mechanical Engineering.

Below are given the interpretations of the Committee in Cases Nos. 364 to 369 inclusive, as formulated at the meeting of September 12, 1921, and approved by the Council. In accordance with the Committee's customary practice, the names of inquirers have been omitted.

Case No. 364

Inquiry: Is it necessary, as indicated in the index to the Boiler Code, to use an extra thick tube for the fusible plug when used with a vertical fire-tube boiler, in accordance with the requirements of Pars. 429 and 430?

Reply: It is the opinion of the Committee that inasmuch as Par. 429 permits of the use of a $^3/_8$-in. fusible plug, it would be desirable to insert it in a tube having a thickness of not less than 0.22 in. in order to allow insertion of at least four threads of the fusible plug.

Case No. 365

(In the hands of the Committee)

Cases No. 366 and 367

(Annulled)

Case No. 368

Inquiry: Is it permissible, under the requirements of Par. 185 of the Boiler Code, to plane or mill down the plates forming the laps of circumferential joints to less than $^1/_2$ in. thickness?

Reply: It is the opinion of the Committee that there is no objection to planing down the laps of circumferential joints to a thickness less than $^1/_2$ in., provided, however, there is sufficient strength left in the joint to conform with the requirements of Par. 184.

Case No. 369

Inquiry: Is it necessary, under the requirement of Par. 195 of the Boiler Code, to increase the thickness of a dished head $^1/_8$ in. when a manhole is inserted and provided the manhole opening is reinforced?

Reply: It is the opinion of the Committee that the requirement in Par. 195 for increase of $^1/_8$ in. in thickness is applicable in any case when a manhole is inserted in a dished head.

Public Hearing on Proposed Code for Air Tanks and Pressure Vessels

The Boiler Code Committee announces progress in the formulation of the proposed code for air tanks and pressure vessels intended to form Section IV of the A.S.M.E. Boiler Code, and that a Public Hearing will be held in connection with the coming A.S.M.E. Annual Meeting in order that all interested in unfired pressure vessels may have an opportunity to participate in the discussion of the proposed rules.

The Hearing will be held in the United Engineering Societies Building, 29 W. 39th St., New York, N. Y., on Monday, December 5, at 9.30 a.m., the opening day of the Annual Meeting. Every one interested in the formulation of this code is cordially invited by the Committee to attend and join in the discussion.

A revised draft of this proposed code is now under preparation and every effort will be made by the Committee to distribute copies thereof to its large mailing list of boiler and tank users and manufacturers well in advance of the Hearing. Copies thereof will also be available for distribution at the Hearing.

Public Hearing on Proposed Code for Miniature Boilers

The Boiler Code Committee announces also that the proposed code for the construction of miniature boilers has been completely revised and will be presented at a Public Hearing to be held in the United Engineering Societies Building, on Tuesday, December 6, at 9.30 a.m. This code is greatly in demand due to the increasing use of the small types of boilers for vulcanizing, clothes-pressing and laundry purposes, and has been looked forward to with interest; this code has not previously been brought before the Society for public discussion. Every one interested in the details of this Code are cordially invited by the Committee to attend and take part in the discussion.

Section of Code on Boilers of Locomotives Completed

Those who have been interested in the formulation of rules for the construction of boilers of locomotives will no doubt be interested to learn that this difficult undertaking has been completed and the Code is being published initially in pamphlet form for distribution independent of the regular edition of the Boiler Code. It will be at first issued in a limited edition with distinctive paper cover but will, upon completion of the 1922 revision of the Code, be incorporated therein and form Section III thereof. This section of the Code is on sale and may be obtained upon application to the office of the Society.

(Continued from page 796)

iliary load, which are, of course, reflected in the house-turbine load. A series of experiments were recently conducted to determine how closely this system could be regulated and what the lag might be between the time that the load on the house turbine was changed and the time when the effect was noticed in the feedwater tank. It was found that any degree of regulation was possible. The house-turbine load could be varied in steps of 10 kw., it being impossible to read variations less than this. The feedwater temperature could be varied by amounts as low as 0.5 deg. fahr., which is as close as an ordinary thermometer can be read.

Table 1 of the complete paper shows actual operating figures for five days, chosen so as to show the operating conditions over a range of loads from 30,000 to 60,000 kw. The quantities shown in Fig. 2 are taken from this table.

MATERIAL HANDLING AN IMPORTANT FACTOR IN THE ELIMINATION OF INDUSTRIAL WASTE

(Continued from page 804)

assign a value to this item after thorough observation and careful consideration. Let us call it X per cent.

The variables in the investment value may be classed as follows:

A = interest charges on investment, per cent
B = interest to provide for upkeep of apparatus installed, per cent
C = interest to provide for depreciation due to age, per cent
D = interest to provide for progress in the art of the particular device proposed (subsequent inventions), per cent
E = interest to provide for extensions to service, per cent
H = additional superintendence and overhead expenses due to change in method, per cent
K = interest to provide for taxes, per cent
F = cost of power, supplies and other variable items in dollars per year

Let S = yearly saving in labor in dollars
and Z = investment in dollars justified by the foregoing considerations

$$\text{then } Z = \frac{S\ (X \text{ per cent}) - F}{(A + B + C + D + E + H + K) \text{ per cent}}$$

Working this out for an assumed set of conditions, assume that the work which under the present methods of moving materials requires four men employed at \$3 per day, 300 days per year, at a yearly cost of \$3600, can be done according to the new method by one man, costing \$900, thus saving \$2700 per year. The plant operates on shift, men employed 80 per cent of the year.

Then	X = 80 per cent	C = 15 per cent	H = 3 per cent
	S = \$2,700	D = 10 per cent	K = 3 per cent
	A = 6 per cent	E = 3 per cent	F = \$400
	B = 20 per cent		

$$\text{and} \quad Z = \frac{(\$2{,}700 \times 0.80) - 400}{0.60}$$

$$= \$2{,}933.33$$

This means, then, that equipment costing under \$2,900 will earn maintenance, interest, depreciation, obsolescence and tax charges and show a saving besides.

Assuming that an electric-storage-battery industrial truck costing \$1,750 will meet the conditions, the yearly operating cost would be as follows:

I = cost of equipment = \$1,750
Y = yearly operating cost
$= I\ (A + B + C + D + E + H + K) + F$
$= (\$1{,}750 \times 0.60) + 400 = \$1{,}450$

Then
$S = \$2{,}700 - \$1{,}450 = \$1{,}250$

This is an actual saving of \$1,250 a year, a return of approximately 71 per cent on the investment over and above all interest charges, upkeep, deterioration and obsolescence.

Only by some such analysis can a real solution of the problem orders, and managers in their ignorance of the underlying conditions, sometimes overlook some of the factors in the problem with the result that anticipated savings are not obtained.

Too much thought and consideration cannot be given to the selection of equipment that not only shows a saving but fits into the general operating conditions of the plant, or suits physical conditions imposed by plant or location, and yet at the same time fits into plans for future extension, development or rehabilitation of the plant. A \$25,000 locomotive crane will last a long time if properly cared for. If future development of the plant does not provide space enough for the utilization of the crane to its best advantage, then the crane may not be the piece of equipment to select initially, even though it will satisfy all of the initial conditions.

A.S.M.E. TO PUBLISH LIFE OF GEORGE WESTINGHOUSE

The mere fact that a Life of George Westinghouse is to be published is an item of interest to every engineer who glories in the great men of his profession. Added interest is given to the announcement, however, by the fact that Col. Henry G. Prout, the author of this biography soon to be published in a limited subscription edition by The American Society of Mechanical Engineers,

George Westinghouse

has used his consummate skill and intimate knowledge of his subject to build a book at once interesting, inspiring and permanent.

This limited edition, which will appear in both morocco and buckram binding, was offered simultaneously to the members of the American Society of Civil Engineers, the American Institute of Mining and Metallurgical Engineers, The American Society of Mechanical Engineers, and the American Institute of Electrical Engineers. Although subscriptions to this edition were to be closed November 15, delay at the printers makes it possible to accept subscriptions up to December 6, and A.S.M.E. members who have not done so are urged to secure a copy of this valuable book by writing to Secretary Calvin W. Rice at once. The subscription binding in buckram with gilt top and silk headband can be procured for \$3.50 postpaid. A special half morocco binding will be sent for \$6.00.

Later a popular edition will be issued and copies of this edition, it is expected, will be available about February, 1922.

MECHANICAL ENGINEERING

A Monthly Journal Containing a Review of Progress and Attainments in Mechanical Engineering and Related Fields, The Engineering Index (of current engineering literature), together with a Summary of the Activities, Papers and Proceedings of

The American Society of Mechanical Engineers

29 West 39th Street, New York

Edwin S. Carman, *President*

PUBLICATION COMMITTEE:

George A. Orrok, *Chairman* Alex. G. Christie

Ralph E. Flanders John T. Wilkin

O. G. Dale

PUBLICATION STAFF:

C. E. Davies, *Managing Editor*

Frederick Lask, *Advertising Manager*

Contributions of interest to the profession are solicited. Communications should be addressed to the Editor.

C 55 The Society as a body is not responsible for the statements of facts or opinions advanced in papers or discussions.

Armament Reduction and the Engineer

THE engineering profession ought to be in favor of a reduction of armament, not alone because it will tend to make it more difficult to begin a war, but also for essentially technical reasons.

From an engineering point of view the actual production of many classes of munitions in anticipation of a war which may not occur for a long time appears to be a wasteful and highly undesirable proceeding.

G. E. Tripp

Such a policy is necessary only as a defence against surprise attack, but it is not true preparedness, and it really tends to weaken the ability of the nation to withstand external aggression.

Modern warfare is not only a contest between the armies and navies of the belligerents, as was the case some three score years ago, but one between the entire industrial and scientific structures of nations.

A truck or tractor factory, a foundry, a plant making motors, fabrics or chemicals, is as much an essential and often deciding part of the military establishment of a nation as is a gun factory. The high maintenance of the productive facilities of a country rests, therefore, at the very foundation of its ability to defend itself against external aggression.

Development of the productive facilities of a country, assuming, as in the case of the United States, the presence of ample natural resources and good natural stock of population, requires two things primarily, and they are ample capital and extensive educational facilities for the people.

Neither of these two conditions can be easily satisfied when Government expenditures reach the disquieting figure of four billions of dollars or more per annum, and when roughly three-quarters of this vast sum is expended for purposes of a military character.

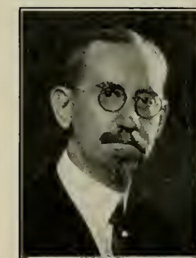
Engineers, more than any other class, realize how much still needs to be done to develop the natural resources of this country, and they also realize that it is by the development of natural resources in the past that the United States attained the state of prosperity and industrial efficiency which permitted it to raise and equip an army of nearly two million men in less than twelve months and to spend without essential embarrassment twenty-five billion dollars in two years for war expenditures.

Armament expenditures as carried out today undermine the ability of countries to attain their highest ideals of national education and industrial development, so that from the point of view of the engineer any agreement to disarm would tend to minimize the possibility of future conflicts and at the same time actually increase the ability of the great powers to protect themselves in case of unprovoked aggression.

The engineer is more and more acquiring a position of intellectual leadership in American communities, and his attitude toward reduction of armament as one of the fundamental questions affecting the industrial and intellectual growth and welfare of the world will have a tremendous influence.

G. E. Tripp.

The Superpower Report



W. S. Murray

NO OBSERVANT person, whether he be a banker, a railroad operator, a manufacturer or an engineer, can have lived or traveled within the boundaries that have been recently marked as those comprising the Superpower Zone without the consciousness that this territory is the most remarkable in the world in its relation to power and transportation requirement.

The United States Government created as effective on July 1, 1920, and engineering organization to investigate and report upon the "possible economy of fuel, labor and material, resulting from the use in the Boston-Washington region of a comprehensive system for generating and distributing electricity to transportation lines and industries." This organization, known as the Superpower Survey, was promptly organized as of that date; all data were collected and assembled, and its report transmitted on June 30, 1921, to Dr. George Otis Smith, Director of the U. S. Geological Survey, under the auspices of whose department the work was conducted.

The usual editing of report text and elimination of surface errors were accomplished in a remarkably short time by Director Smith's department and the report was transmitted to the President by Secretary of the Interior Fall on November 5, 1921, and has become the people's document known as Professional Paper 123.

As chairman of the Superpower Survey I was naturally brought into close personal and professional touch with the engineering associates that I was permitted to select. The report is divided into three major sections of investigation:

1 Electric power production and transmission
2 Railway electrification
3 Industrial electrification.

Respectively at the heads of these departments of investigation were Mr. Lorin E. Imlay, Dr. Cary T. Hutchinson, and Mr. Henry W. Butler. Mr. Henry Flood, Jr., as engineer-secretary of the Superpower Survey, was assigned to the duty of collaborating with these three departments and preparing the data in as near form to report text as possible.

To these men, their able assistants and other outside associated eminent engineers, belongs the credit for the report, for it was clear that only through the utmost coöperative effort and full agreement on the part of the entire engineering staff could it be produced within the time assigned by Congress.

During the early period of the work, engineering staff meetings were called every two weeks. Procedure and progress in all departments of the work were discussed at these meetings, and as it advanced the interval of time between them was increased. Eighteen engineering staff meetings were held. Contemporaneously, but at intervals of two months instead of two weeks, the Advisory Board was convened and our progress discussed. Too much cannot be said for the loyal attendance and assistance resulting from these well-attended Advisory Board meetings led by Prof. L. P. Breckenridge, head of the department of mechanical

chairman of the Advisory Board.

The report is summarized in its first pages, where among the conclusions presented it is stated that no later than 1930, through the unionization of electric utility, power production and the electrification of certain divisions of the railroads within the zone, and the acceptance of electric power from the electric utilities by the isolated industries in lieu of individual plant generation of their power, over $500,000,000 can be saved annually, and that the investment to cover will yield not less than 30 per cent. Such a possibility supported by the fact that in so doing 49,000,000 tons of coal can be saved annually, makes not only the engineer but any citizen in the zone feel that there may indeed be some truth in the oft-repeated statement that three prime powers in Europe could live in comparative luxury on the wastes of this nation.

W. S. Murray.

Problems and Progress of Iron and Steel Metallurgy in France.

THE Great War ended three years ago, but the iron and steel industry in France still feels its effects and will feel them for many years to come. The results have been terrible.

Prof. Jacques Cavalier

For more than four years the enemy occupied about seven per cent of the territory of my country, the parts thus invaded being among the most important and the richest above all for metallurgy. It is just as if in the United States the metallurgical industry had been deprived of the states of Pennsylvania, Ohio, Maryland, Virginia, Carolina and Georgia.

A few figures will serve to show the influence of the invasion on production.

	—Production in 1913—		
	Total	Invaded zone	Proportion in the country invaded
Coal[1]	40,844,000 tons	20,000,000 tons	50 per cent
Coke	4,000,000 tons	3,080,000 tons	76 per cent
Iron ores	22,000,000 tons	18,000,000 tons	86 per cent
Cast iron	5,207,000 tons	3,336,000 tons	64 per cent
Steel	4,686,000 tons	2,934,000 tons	63 per cent
Blast furnaces	170	85	50 per cent
Open-hearth furnaces	164	48	30 per cent
Bessemer converters	100	53	53 per cent

[1] Besides the twenty million tons in the invaded country, seven million of the region of the north were under the fire of the enemy.

This enormous cutting down of the means of production would not have been very serious if, as the leaders of the different armies had expected, the war had been short and had been conducted with only the munitions on hand. But after the Battle of the Marne these munitions were exhausted, and it became necessary to organize for a war of indeterminate length and to assure an unfailing supply of munitions to the armies.

At the beginning provision was made for a production of ten to twenty thousand shells a day; toward the middle of 1917 there were being turned out every twenty-four hours 300,000 shells for 75-mm. guns, 30,000 for 120-mm., and 50,000 for 155-mm. guns, without counting projectiles of larger caliber. In this our first effort we asked foreign countries, friendly or neutral, for the necessary metal. The American industries furnished us with considerable quantities of steel, and thus gave us help of inestimable value.

At the same time we sought to increase the means of production of metal and new installations were put in with a speed which doubtless is usual in the United States, but which is much rarer in Europe. In February, 1916, La Société Normande de Métallurgie resumed the work it had started in the neighborhood of Caen at the beginning of the War; in January, 1917, it put into operation a battery of coke ovens; in August a 400-ton blast furnace; and in, June, 1918, a steel works begun in January, 1917, and comprising five 30-ton converters and five 30-ton open-hearth furnaces.

Other industrial establishments made like efforts and as a result during the War there were built in France:

	Production, Tons
12 Blast furnaces	600,000
103 Open-hearth furnaces	1,560,000
47 Converters	242,000
21 Electric furnaces	56,000

Before the War France had 24 electric furnaces.

If, after the victory of the Allied Armies and the liberation of the invaded territory France had found her workshops intact, the effort made during the War would have been followed by a growth of her industrial power. We know that this was not so. In the invaded regions of the north the Germans had wiped out the greater part of the coal mines and had destroyed 11,500 plants. This destruction had no military purpose; it was methodical and studied, the object being to place our country in a position of inferiority in the economic scale. I know personally of a small establishment in the suburbs of Lille where the Germans, not having time to destroy the steam plant, rendered it useless by filling it with concrete.

The work of rebuilding the destroyed factories is now under way and will require several years, especially in the case of the collieries. On the other hand, numerous plants in the interior of the country have increased in size and have put in more modern and better equipment. In general, however, this work has been held up for a year or so by the rise in prices and by the industrial crisis common to all industrial countries.

At the end of the period of which I have attempted to show some essential characteristics, the dominating idea was to produce at a maximum by the usual methods without seeking new ones. At the same time, it is necessary to point out several things relating to the progress of the iron and steel industry.

First, the development of the electric furnace. Among European nations France is one of the richest in hydraulic power, the total energy available being from eight to ten million horsepower. At the beginning of the War, however, only a little more than a million horsepower had been harnessed, of which 750,000 was in the Alps and 150,000 in the Pyrenees.

The power resources of Pyrenees are not only much less than those of the Alps but proportionally they have been less developed. This is about to be corrected.

The building and equipment of a hydroelectric system generally requires many months, often several years; we hesitated to undertake the work as long as it was believed that the War would be of short duration, and it was only about 1916 that it was begun. We have thus been able to equip in addition to what we already had about 400,000 hp., while 400,000 hp. more are in process of installation. It is necessary to take into consideration also the projects which are now being studied for the harnessing of the Rhone and the Rhine. Only a part of this new energy has been applied to the steel industry; the electric furnace has above all been reserved for high-grade or special steels, and for the preparation of ferro-alloys and silicon alloys for which it is indispensable. The greater part of the electric energy was destined for purely chemical manufacture: electrolytic chlorine, chlorates and perchlorates, and especially synthetic nitric acid, for which we laid out and commenced to realize a vast program when the enormous increase in the number of ships torpedoed caused us to have serious fear for the continuation of our supply of nitrate of soda from Chile.

With the ending of the War these latter needs have almost disappeared. The plants equipped or in process of installation have become available for other uses, namely, railway electrification, metallurgy, etc. Indeed, the writer can cite in the neighborhood of Toulouse two such plants, that of Pamiers and the La Société du Saut du Tarn à St. Juery, near Albi, that have recently made important installations of electric furnaces for the manufacture of steel.

In another plant in the Pyrenees region it is proposed to install a closed furnace for the direct treatment of ore, particularly pyrite cinder. Although the electric furnace is well adapted to the treatment of sulphide residues, it is nevertheless questionable whether the direct production of cast iron can be accomplished economically in a country where electric energy finds so many remunerative uses.

Second, the electric furnace is used for the manufacture of

synthetic cast iron according to the process outlined by Keller long before 1914 and which was made use of during the War. An electric furnace is charged with turnings and small scrap of iron and steel with a given quantity of coal in the presence of a slag which makes the operation more regular and in addition can bring about desulphurization. If it is necessary to increase the silicon content, silica and the corresponding quantity of coke are added. The cast iron thus obtained is according to specification and very pure, particularly in regard to the sulphur content. The process has the advantage of permitting the easy utilization of turnings, of which there was a great abundance during the War, and it has furnished large quantities of cast iron for the manufacture of projectiles. I have lately seen in the Pyrenees a plant normally making silico-manganese which, not being able to get rid of its stock on account of the industrial crisis, utilizes part of its electric furnaces for the manufacture of synthetic cast iron. At the present prices of good cast iron and of scrap and turnings it is actually a paying operation, but whether it will be when conditions have become normal once more, is a question.

Third, the development of the use of scientific methods. The progress realized by systematic study in the laboratory usually penetrates slowly into industrial practice. Producers in the average industry have a tendency to consider the laboratory as a luxury which does not pay.

The War, in bringing together for the national defense the industrialists and the men of science in the process of intensive production of metal, has powerfully contributed to the employment and to the diffusion of new and precise methods of work and of control.

The measurement of high temperatures has become very general, especially for the heat treatment of shells.

Microscopic examination has been carried out systematically, as, for example, in the manufacture of cartridge cases, where the brass undergoes successive annealings. A simple and rapid microscopic examination shows whether annealing has been done at the right temperature and under the right conditions, or if it is necessary to reanneal before further mechanical working.

In regard to the mechanical tests which are commonly used, special mention should be made of the Brinell test and the shock test on notched bars. The Brinell test has been used particularly to control the heat treatment of shells; it is employed before any treatment, after quenching, and at the end of the treatment after drawing. Special schemes have been studied and put in practice for eliminating the influence of time in this test in order to allow great rapidity of execution without affecting precision. On a series of pieces 600 impressions an hour have been easily obtained. During the period when the manufacture of shells reached its maximum, say, 300,000 to 400,000 a day, it can be said that there were 800,000 Brinell tests made in the same time. The shock test on notched bars made its appearance before the War, but it was introduced very timidly and met with much opposition on the part of the manufacturers. During the War the Aeronautical Branch, which had need of exceptional guarantees, found the introduction of this test indispensable in the inspection of crankshafts and connecting rods for aviation motors. These rods had to reach a number corresponding to 9 to 10 kg-m. on a test bar having a section of 10 by 10 mm. with a notch 2 by 2 mm. and rounded at the bottom.

While these different methods were doubtless employed before the War in a small measure, they rapidly became common during the conflict, even in the most old-fashioned workshops. By a constant and accurate control they caused a large reduction of rejections and in this way speeded up production. Manufacturers come to accept clauses in specifications with which they would have nothing to do previously.

Without doubt these good industrial habits which were acquired under the force of circumstances will continue. And thus the War will have contributed to the progress of our metallurgical industry, even though it be in a measure which only compensates to a slight extent for the great losses resulting from the destruction of our factories.

Jacques Cavalier.[1]

[1] Rector of the University of Toulouse, Toulouse, France; French Exchange Professor, at present at School of Mines, Columbia University, New York.

An Interprofessional Conference

On October 27 representatives from each of eight important professional groups met at luncheon at the City Club in Philadelphia, as guests of the American Academy of Political and Social Science, for the purpose of ascertaining the present status as to ethical standards in each of the professions, and also for the purpose of securing suggestions as to whether or not public welfare could be advanced in any way at the present time by a discussion of both the need for better standards and the achievements as to standards in each of the professions. Of course questions of organization as an aid in the development of ethical conduct played an important part in the discussions.

At this conference Calvin W. Rice and Morris L. Cooke represented the engineers; W. E. Mikell and Roland S. Morris, the lawyers; Graham Taylor and Mary Van Kleeck, the social workers; R. D. Kohn and C. C. Zantzinger, the architects; W. D. Lewis and Clyde L. King, the teachers; A. D. Whiting, the doctors; Edmond Sterling, the journalists; and C. J. Rhoads, the business men.

The conference decided unanimously that the Academy should issue a symposium as soon as possible dealing with the ideals and practice as to ethical standards in each of the leading professions. More important still, the conference was requested by the Academy to act as a permanent agency to plan interprofessional activities and to seek to inspire organizations to create and enforce ethical standards in the professions not yet very thoroughly organized. Thus, it was the opinion of the conference that there was no reason why journalists should not have an organization and ethical standards comparable to those of the engineers and notably of the architects. The need was also pointed out for such organization among social workers and particularly among business men. The Academy agreed to publish such a symposium this coming May, and steps have already been taken toward that end. Steps are also being taken to advance the establishment and the maintenance of recognized ethical standards among journalists, teachers, social workers and business men. Interprofessional gatherings similar to this Philadelphia meeting are projected in a number of cities.

The keynote of the meeting was the maintaining of a public point of view looking toward a standard of conduct which will protect society from any menace from the professions as well as make the professions conscious of their public obligations and opportunities. It was very eloquently pointed out at this meeting that the professions are in a very peculiar sense the custodians of the service motive, and that if civilization is to be served the professions must see to it that this service motive is visualized and made dominant in every form of human activity.

Clyde E. King.[1]

New Member of Engineering Foundation Board

Arthur Lucian Walker, professor of metallurgy in the Schools of Mines, Engineering and Chemistry of Columbia University, New York, has been appointed representative of the American Institute of Mining and Metallurgical Engineers on the Engineering Foundation Board, to succeed Dr. Joseph W. Richards, deceased.

Professor Walker was engaged in chemical and engineering work until 1887, when he became general superintendent of the Old Dominion Copper Co., Arizona. Six years later he was appointed manager of the Baltimore Electrolytic Refining Company and in 1899 manager of the Perth Amboy, N. J., plant of the American Smelting & Refining Company, of which he was director from 1906 to 1907. He has been professor of metallurgy at Columbia since 1908. He served as consulting metallurgist at large for ordnance, War Department, 1917–1918.

In 1898 Professor Walker invented the Walker mechanical casting machine, which revolutionized methods used for casting copper into refined shapes and is now extensively used in all copper-producing countries in the world. In 1902 he invented a new system of tank-room arrangement, for use in electrolytic copper refining, which has been installed in practically all copper-refining plants built since that time. He has been retained by a number of large companies as consulting metallurgist, specializing in copper.

Two Strong Speakers Will Address Leading Session—Important Meetings on Education Scheduled—Interesting Social Features and Excursions Planned

Speakers for Principal Session

Two speakers have been announced for the principal session of the meeting on Monday afternoon. Fred J. Miller, Past-President of the Society, will interpret the spirit of the report of the Committee on Elimination of Waste in Industry. He will be followed by W. H. Sullivan, Vice-President and General Manager of the Great Southern Lumber Company of Bogalusa, La., who will outline the principles followed in the elimination of wastes in the Bogalusa development of the Great Southern Lumber Company, which is an outstanding example of what can be done in an industry which has suffered from great wastes that have seemed unavoidable.

Education

Attention is again called to the two notable sessions on Education. Monday evening, Education and Training in the Industries will be considered. Thursday afternoon the Society for the Promotion of Engineering Education will hold a joint session with The American Society of Mechanical Engineers, at which the needs of Professional Education for the Industries will be discussed by F. C. Pratt, vice-president of the General Electric Company and president of the Yale Engineering Association; J. E. Otterson, president of the Winchester Repeating Arms Company; Dexter S. Kimball, dean of the College of Engineering, Cornell University, and president-elect A.S.M.E.; and A. G. Christie, professor of mechanical engineering at Johns Hopkins University, and chairman of the A.S.M.E. Power Division.

Many Features to Interest Ladies

The technical side of the meeting has been well developed and its success from this point of view is assured. The interest of the ladies, however, is greatly desired so that the social features which have been given careful consideration in the plans for this meeting will be equally successful. Many ladies who have become enthusiasts of A.S.M.E. meetings complain that they are obliged to seek diligently for the information they want about the meeting activities that will be of interest to them. To avoid this criticism, each member should take his circular home and go over the points of interest that will be of value to the ladies of the family.

Changes in Tentative Program

As indicated in the circular which was sent to the membership during November, a General Session will be held on Thursday afternoon and another General Session on Friday afternoon. The paper by Major Gilbert D. Fish on Stresses and Deformations in Flat Circular Cylinder Heads, a Mathematical Analysis, and the paper by R. F. Wood on Control of Centrifugal Castings by Calculation, have been assigned to the Thursday afternoon session. The Friday afternoon session will be devoted to the paper by F. W. Dean on Tests on Emergency Fleet Boilers Using Oil Fuel. At the same session a paper by Messrs. L. A. Quayle and E. H. Brown giving Results of Tests on Pumping Engines of the City Water Works of Cleveland and a paper on Steam Condensing Plants by Paul A. Bancel, will be presented. The paper presented by Messrs. Quayle and Brown gives noteworthy results of tests on pumping engines, the thermal efficiency of the engine tested comparing more than favorably with any other prime movers that have been tested recently. Mr. Bancel's paper will be presented by title and the meeting will be thrown open to a discussion thereof.

The Aeronautic Division has completed its program and will have three papers as follows:

- Study of the Elastic Properties of Small-Size Wire Cable, R. R. Moore
- Commercial Operation of Airplanes, Maj. L. B. Lent
- Problems of Commercial Operation in the Light of European Experience, R. B. C. Noorduyn

A paper of vital importance in the Diesel field will be presented at the Gas Power Session. Elmer A. Sperry, after twenty years of experiment, has completed a successful compound Diesel engine and will make public the results of his work. It can be confidently stated that the presentation of particulars of this epoch-making device will be of great interest and will develop important discussion.

The Fuel Division will complement its program by showing moving pictures of stoker operation. This film, prepared by R. Stanford Riley, of Worcester, Mass., and viewed by several representatives of the Society, all of whom are enthusiastic in their statements as to its value, will show actual combustion conditions in underfeed stoker operation. Mr. Riley will introduce the film with an account of the experiments which made this moving picture possible.

Student Session

The student members of the Society will hold a session on Thursday morning. A paper will be presented by W. K. Ramsay of M. I. T. on Draft-Tube Design, and another by George E. Lyon of Rensselaer Polytechnic Institute. This session gives the older members a fine opportunity to show their interest in the valuable work being carried on by the Student Branches of the Society.

Excursions and Social Features

The excursion program so far arranged offers opportunities to visit the Essex Power Station of the New Jersey Public Service Company, and the plant of the Seaboard By-Product Company of Jersey City which obtains numerous by-products in addition to coke and gas from coal. Their plant will be of considerable interest to the Fuel, Power and Gas Power Divisions. On Friday afternoon an excursion will be made to the White Star liner *Olympic*. Members of the Society will be given the opportunity to inspect the entire ship and the passenger accommodations will be open to the ladies of the party. Afternoon tea will be served in the dining saloon.

Great enthusiasm is developing for the social events to be held in connection with the meeting. The dinner-dance which will be held Thursday night at the Hotel Astor gives promise of being one of the most successful functions that the Society has held. The chairman of the committee in charge of this event is Major Edward Van Winkle, who has had much experience with affairs of this sort, and he has given assurance that the entire function will be interesting.

College Reunions

The graduates of technical schools are looking forward to the various reunions to be held on Friday evening of the Meeting. Notices will be sent out by each of the alumni organizations regarding their respective affairs. The Cornell men are planning an exceptional event in a dinner to be held on this evening at the Waldorf-Astoria in honor of Dr. Farrand, newly installed president of the University, and Dean Kimball, head of the College of Engineering, who will take office as president of The American Society of Mechanical Engineers during this Annual Meeting. Other institutions which will hold reunions are the University of Illinois, Massachusetts Institute of Technology, Purdue University, Rensselaer Polytechnic Institute, Stevens Institute of Technology, Worcester Polytechnic Institute, and also the Princeton Engineering Society.

Business Meeting

The discussion of the Constitution and of various Society policies which has been planned for the Business Meeting has already aroused the attention of the membership. A stirring meeting is assured. Further particulars of the meeting will be found on pages 133 and 134 of Section II of this issue.

The Federated American Engineering Societies

Review of Progress Made by Federation during First Year—Summary of Committee Activities—Solidarity of Engineers the Chief Objective—The American Engineering Council to Meet at Washington Early in January

With the completion of the first year of The Federated American Engineering Societies it is well to review the progress made in consolidating the engineers of the country and providing a medium through which they may act as a unit in rendering public service involving engineering knowledge and experience. Such a review covers growth in membership, development of organization, definite work accomplished, and projects in hand, and may include plans for the future.

The Federation is a growing organization. Of the 30 national and 41 local and regional organizations which met in Washington on June 3 and 4, 1920, to create the F.A.E.S., representatives of 21 member societies and 9 organizations considering membership were present at the first meeting of the American Engineering Council, the governing body of the Federation, held in Washington Nov. 18–20, 1920. There are now 29 member societies, representing over 45,000 engineers, and applications for membership are receiving action at every meeting of the Executive Board of the American Engineering Council.

The work of the Federation is carried on under the direction of its governing body, and through standing and special committees representative of the member societies. Frequent requests for assistance in various state and national activities have resulted in the creation of many new committees during the past year. The present organization is shown by the accompanying chart, which indicates the relation of the committees to the governing body and to each other and gives their personnel.

It will be noted that the majority of the committees are dealing with matters of national importance. The value of the assistance that can be rendered by such an organization representing some of the best engineering minds of the nation, is immeasurable. The fact that governmental officials, both legislative and executive, heads of governmental departments, U. S. Chamber of Commerce, manufacturers' associations, etc., are constantly turning to the Federation for assistance, information and suggestions, indicates that it is recognized as an influential and constructive body.

One of the most constructive pieces of work accomplished by the Federation is the investigation conducted by its Committee on the Elimination of Waste in Industry. The report of this committee, which has recently been published, has attracted wide and favorable attention, has been of great assistance in various conferences, and has stimulated further action in several organizations. Several committees of the Unemployment Conference found the report valuable in their work. Messrs. Edward E. Hunt and Sanford E. Thompson, both members of the Waste Committee, were members of the conference, the former as secretary. The boot and shoe, the ready-made clothing, the building, and the printing reports have all been used in connection with the settlement of labor troubles in these respective industries. The findings of the Waste Report have been or will be considered by the following groups in their annual or semi-annual meetings: National Cost Accountants Association; Society of Industrial Engineers; Industrial Management Council of the Chamber of Commerce, Rochester, N. Y.; United Typothetae of America; and The American Society of Mechanical Engineers. Official inquiries have come from Australia, Canada, Czecho-Slovakia, and England concerning the purpose, methods, and results of the investigation. The Department of Commerce has given careful consideration to the Waste Report and through the Bureau of Standards will carry on some of the investigations recommended therein.

At the present time there are several bills pending in Congress in which the Federation is taking an active interest. Among these are the War Minerals Liberalization Act, and bills concerning topographic mapping, the status of sanitary engineers, and patents. The first-named would reopen cases adjusted by the War Minerals Relief Commission, of which Philip N. Moore and Horace G. Pomeroy were engineer-members. The F.A.E.S. is opposing this act and is supporting a resolution introduced to provide for the return to the U. S. Treasury of the fund of several million left by the Commission. A bill providing a definite plan for the completion of a topographical map of the entire United States is also being supported by the Federation; and it has helped draft and had introduced a bill securing commissioned status for sanitary engineers of the U. S. Public Health Service. Through its Patents Committee, it is opposing the Stanley bill and supporting the Lampert Bill. Previous issues of Mechanical Engineering have contained details concerning these items of legislation. Owing to the activities of the Patents Committee the Stanley Bill has been recommitted to the Patents Committee of the Senate, and hearings will be held at which representatives of the F.A.E.S. Patents Committee will be present.

Representatives of the F.A.E.S. have coöperated with the Department of Commerce in organizing a conference of highway engineers to consider the advisability of "fall-letting" of highway construction contracts. The statement prepared by this conference formed the basis of a letter addressed by the Secretary of Commerce to the governors of all the states, in response to which favorable comment and action have been forthcoming.

Information is also being gathered pertaining to letting of fall contracts for other types of construction than that of highways.

The F.A.E.S. has supported activities leading to the creation of a Department of Public Works. Present indications are that civil engineering functions of the Government will be placed under one head and that the Department of the Interior will be divided into two divisions, one of public domain, and one of public works. In the latter division will be assembled almost all the governmental activities that the engineers have advocated should go into a Department of Public Works.

Members of the Federation's Registration Committee and Executive Board have taken active part in hearings and appeared before legislative committees dealing with the registration of engineers, exercising their influence to have a uniform law passed.

The Federation has maintained an employment bureau in New York and has coöperated with various agencies of similar intent in an effort to reduce unemployment. Recent action was reported in the November issue of Mechanical Engineering.

Among other undertakings in which committees and representatives of the Federation have assisted are the following:

- Classification and Compensation of Engineers
- National Board of Jurisdictional Awards in the Building Industry
- New York State Government Reorganization
- Types of Government Contracts
- Length of Shifts in Continuous Industry.

As a means of distributing information concerning the activities of the Federation, a weekly digest has been issued to engineering organizations, colleges, government offices, and individuals. Over 1400 of these are now being sent out weekly. While Congress is in session weekly digests on legislative and departmental news are also issued to those desiring them. Over 400 stories have been sent out to the press by the publicity director since January 1, and the major waste stories have had a circulation each of at least 14,000,000. The state administrative committees to be organized will be a further means of publicity and closer contact with individual engineers.

The chief objective of the Federation for the next few months will be to solidify its membership. It is realized that the individual engineer is not thoroughly acquainted with the purposes and activities of the Federation. Until engineers in general are more fully informed, the F.A.E.S. cannot hope to function to the best advantage. Arrangements are therefore being made to have some member of the Executive Board appear before every member society during the next two months, bringing to the individual engineer of each society the thought that the purpose of the Federation is

to enable him to render the public service that his training and experience affords.

The Committee on Regional Activities has recommended that the number of districts be increased from 6 to 8; in arranging these districts unity of local interest will be the paramount object.

The Executive Board for 1922 will be composed of 30 members, 16 representatives from national societies, 8 regional directors through which local societies will be represented, and 6 elected officers.

The next meeting of the American Engineering Council will be held at Washington, January 5 and 6, 1922. It will mark a new chapter in the history of the organization. With its plans of organization largely disposed of, the experience of a year back of it, and its work guided by a most efficient personnel, the Federation need not be apprehensive of the future.

The Waste Report

On October 20, 1921, The Federated American Engineering Societies issued printed copies of the report of the Committee on Elimination of Waste in Industry. This book of over four hundred pages contains the reports of a committee of engineers on their investigations of the building industry, men's clothing manufacturing, shoe manufacturing, printing, metal trades and textile manufacturing, as well as general reports on unemployment, strikes and lockouts, legal machinery for adjusting disputes, industrial accidents, health of industrial workers, eye conservation and purchasing and sales policies.

These reports are preceded by a summary which shows sources and causes of wastes and gives recommendations for the elimination of waste. The questionnaire and valuation sheet used by the field engineers in collecting information on which they based their reports are also explained in detail. Each of the engineers' field reports contains the evaluation sheet for the plant investigated.

The foreword by Herbert Hoover sums up the purpose and character of the book:

> This reconnaisance report on waste in industry is the result of five months of intensive study, carefully planned and rapidly executed. A part of its value lies in the speed with which the work has been done, and the promptness with which it presents definite lines for future action. It reveals facts which may serve as a foundation for an advance in American industry. It has a special message for government officials, financial, industrial and commercial leaders, labor organizations, economists, engineers and research groups, the general public and the press.
>
> We have probably the highest ingenuity and efficiency in the operation of our industries of any nation. Yet our industrial machine is far from perfect. The wastes of unemployment during depressions; from speculation and overproduction in booms; from labor turnover; from labor conflicts, from intermittent failure of transportation of supplies of fuel and power; from excessive seasonal operation; from lack of standardization; from loss in our processed and materials—all combine to represent a huge deduction from the goods and services that we might all enjoy if we could do a better job of it.

Section I of the report, which summarized the findings of the Committee, was abstracted in the September issue of MECHANICAL ENGINEERING. The entire report will be reviewed in greater detail in the January issue. The book is on sale through the McGraw-Hill Book Co., Inc., New York.

The Financing and Managing of Large Undertakings

Problems of Raising Money and Choosing Leaders Considered by Joint Meeting of New York Sections of the Four National Engineering Societies

A NOTABLE scheme of coöperative meetings has been developed by the New York Sections of the American Society of Civil Engineers, the American Institute of Mining and Metallurgical Engineers, the American Institute of Electrical Engineers and The American Society of Mechanical Engineers. Topics of interest to the entire engineering profession will be presented at four joint meetings during the fall and winter. The first meeting, devoted to the subject The Engineer in Finance and Management, was held October 19 in the Engineering Societies Building and the subject and speakers drew an audience that filled the auditorium to capacity.

Farley Osgood, chairman of the New York Section of the American Institute of Electrical Engineers, presided and introduced as the first speaker Mr. Arthur B. Leach of the A. B. Leach Company, whose subject was The Financing of Large Engineering Undertakings.

THE FINANCING OF LARGE UNDERTAKINGS

In his opening remarks Mr. Leach emphasized the principle that individuals and the country as a whole are subject to and limited by environment. The country storekeeper cannot hope to do the business of a Wanamaker, so when considering the important subject of the financing of great developments, environment must be faced, and the speaker proceeded to portray present conditions which limit the financing of engineering projects.

As a basis for his picture of present-day limitations, Mr. Leach quoted as follows from a magazine article printed in 1914:

> The year 1914 has marked a culmination of the area of high finance which set in over fifteen years ago. Practically all the "bubbles" growing out of that extraordinary period have now burst and security values as a whole have returned to approximate bases of actual values.
>
> Public opinion, which for ten years has generally been antagonistic to corporate interests, this antagonism naturally growing out of the high-finance policy, has now definitely veered and the pendulum is about to swing the other way. The Federal Reserve Banking System has for the first time in history given legitimate business opportunity a firm basis on which to build, and has eliminated all dangers of financial panic of the style of 1873 and 1907.

Since 1914 the per capita debt in the United States has grown from \$9.63 to \$224.81, in Great Britain from \$75.03 to \$814.08, and in other European countries in a similar manner. Money rates have advanced since 1914 from 3 5/8 to 6 3/8 per cent for call money and from 4 7/8 to 7 1/8 per cent for time money, a fact that must be faced in determining the wisdom of financing an enterprise.

Mr. Leach stated that an estimate of tonnage now afloat indicates a total in excess of 60,000,000 gross tons, approximately 11,000,000 gross tons over the figure for June 30, 1914. This condition coupled with a lessened volume of international trade has forced shipping rates to unprofitable levels, with the resultant tying up of great sums of money.

In discussing the financing of railroads, Mr. Leach enunciated the axiom that it was necessary for an enterprise to be reasonably profitable, and pointed out that the investment return in railroads had dropped from 5.68 per cent for the year ending June 30, 1910, to 3.68 per cent for the year ending December 31, 1918, and to 0.78 per cent for the year ending December 31, 1920.

Ohio needs \$118,000,000 for its public utilities and 170,000 new homes for 850,000 people, but Mr. Leach showed that for every dollar earned in Ohio ten cents is taken in local taxes. In New York City the stock watering of the rapid-transit companies upon their combination many years ago caused a loss of public confidence which has never been regained. In the operation of street railways, Mr. Leach showed that recent increases in fares have brought about considerable improvement.

Quoting Abraham Lincoln, who said that "public sentiment is everything, with it nothing can fail, without it nothing can succeed," Mr. Leach made the plea that greater publicity be given by public-utility managers.

The large foreign loans at high rates of interest have also rendered domestic financing more difficult. Foreign governments need money and are willing to pay for it at rates that domestic enterprises cannot meet.

Mr. Leach pointed to the exceedingly low wage rates in Germany as a vital reason for developing every per cent of usefulness in our present industrial installations to protect us from an overwhelming influx of foreign goods. He pointed out the case of the Government expenditure of \$72,000,000 for a powder plant at Nitro, W. Va., and emphasized the need for the determination of the most economic use of the development.

Mr. Leach summed up his thesis in the following words:

enterprises which have been overdeveloped, a surplus will come, and then the market place will have funds for the development of new enterprises. But first, we must make all of our operations efficient, we must get down to a basis where we can compete with foreigners, who are going to ship large quantities of goods here on account of the low prices of labor abroad. We must make efficient and economic in their operation these great plants which the Government or individuals built under wartime pressure; because in all of our operations of an industrial or commercial or a financial character, we must aim to be efficient in as high a degree as we can. Before any new enterprises can be started and completed, we must force home to the public what was coming to be true in 1914, we must get rid of this antagonism for new development, and we must make common among all of the people the belief that these enterprises are for the common good, and for the good of everybody.

If we are to get to the place where great financial plans can be carried out, we must not lose time being glad that the other fellow has had a devil of a time in the last three or four years, but we must spend more time trying to work out these problems that the war has left on our hands, so that we shall get back to a normal basis of mutual confidence, or mutual belief that this country is going ahead, and that we are going to be able to build again that temple which our fathers started, and which has been stopped by this crisis of world fury and world hate.

The Engineer's Shortcomings as a Financial Manager

The Chairman then introduced Philip Cabot, of Boston, a member of the firm of White, Weld and Company, who spoke on the subject The Engineer a Failure as a Financial Manager. His remarks were in part as follows:

Essentially the great engineer as born and trained in our times is of the scientific, studious type, disciplined, severe, ascetic by nature and by training in the schools and in life.

Your builder and leader of great industrial enterprises is cast in a different mold. He is essentially an idealist, imaginative, enthusiastic, impulsive intensely human, a dreamer of dreams with the power to make the dreams come true. In short, an artist capable both of great imaginative conception, and fine technical execution; possessed of the power both to conceive and do.

A glance at the history of American industry during the last fifty years will show that the great figures are all men of this type; Vanderbilt, Hill, Ripley, Carnegie, Schwab, Rosenwald, Woolworth, Armour, McCormick, McElwain, Endicott, Ford, Westinghouse, Coffin, Vail. As one example, take Vail, of the telephone company. Distinctly less remarkable than some of his predecessors in intellectual power, and scientific training, he took the company when to some of us it seemed about to go upon the financial rocks and left it the most shining success of any public utility in the world. His success was due, not to commanding intelligence but to imaginative power and the capacity to select and direct men.

And look at our dear Henry Ford with all his sins of ignorance upon his head, who has, as it were, over night leaped from nowhere into the multi-millionaire class, leading an automobile industry as large in some dimensions as all others in the country put together, and perhaps the one successful one.

The reason why such men succeed is obvious. They have faith; they believe in things they cannot prove, possess the courage to stake their reputation and their future on their ability to make their dreams come true, and obtained from these qualities the power to inspire with enthusiasm and loyalty the great body of men under their command who are their necessary tools, controlling them with the precision and power with which the great painter handles his brush.

Such a spirit in an organization is an essential (one is tempted to say *the one* essential) of industrial, as of military, success; unquestioning loyalty and the willingness to take desperate chances at the word of command. Leadership in any field demands this type of man, this power to inspire. With it success will come in spite of many weaknesses. Without it success will be difficult except for commanding genius.

The foregoing are examples of shining success and the reasons for it. But we learn more, as a rule, from our failures, and it will be instructive to note some of these. Perhaps the most striking illustration of failure which we have today is the railroad business. The present condition of these public utilities contrasts very sharply with the condition of the telephone company as it grew under the leadership of Mr. Vail. Many reasons are assigned for the collapse of the railroads, and like all other human things, there is doubtless no one cause, the result being the product of many causes. But it is very striking to note the change in the type of men who now lead the great railroad systems, as compared with the men who led them when they were successful. Formerly the railroad leaders were traffic men and salesmen and builders, today the railroads are run by operating men, engineers, and the traffic men have been pushed aside. The failure of the railway executives to meet the demands of the times is not exactly their fault. They have been subject to state regulations and federal regulations, which has put them under an impossible handicap. They have the nominal position of responsibility without power, and no wonder they fail in successful leadership, but it is inevitable that they should fail. The huge army which these men command, far from being inspired by the enthusiasm and loyalty which are essential to success, is admittedly upon the verge of mutiny. For years the relation of the great railroad executives to their employees has been such as to breed disloyalty. The effect of Government regulation as designed and administered during the last twenty years has been to develop in railway executives and in leaders of the great railway unions the most conspicuous and magnificent example which the world has ever seen of the great game of "Anti" and "pass the buck."

I do not say, nor do I believe, that it is impossible for an engineer to be natural handicap is increased by our present methods of training to such an extent as to make him an unpromising candidate for promotion to such positions, and I say this with full knowledge of the fact that his selection to fill them has become increasingly common of late years, especially in public-service corporations.

If this fact seems to you extraordinary the reason is not far to seek. The directors and officers of corporations are in theory elected by the owners, (to wit, the stockholders) but nothing is further from the fact. Stockholders are in practice a flock of sheep incapable of concerted, intelligent action, but eager to follow any leader, so that the task of selecting corporation managements falls upon the banker, or financial godfather of the enterprise. Such men, cautious by nature, and made doubly so by experience, yearn for a sure thing and welcome the engineer with his mathematical accuracy. Your engineer at least will not exceed his estimates, will tell them in advance what he will do and do it, while your most visionary promoter must forever be watched and guided. With an engineer at the wheel the company will run itself and the banker and director can sleep in peace. At least he thinks so, and for a time he can. But there is apt to be a rude awakening when he discovers that the business has gradually evaporated, wages have shown a disconcerting tendency to eat up profits, and customers are becoming surly.

In this case, as in all others, the search for the sure thing fails; temporary peace is purchased at the cost of ultimate failure, and the practice must be abandoned. The bankers must select men of enthusiasm, courage and vision and must put over them boards of directors who are capable and willing to direct. Your dreamer without direction will wreck you faster and more certainly than your man of science. But with adequate direction and control he is your safest man, and if our engineers are to occupy such positions with success their education and training must be profoundly modified.

The great builders and leaders of large industries in the United States have all possessed the following qualities:

1 Imagination, giving
 - *a* The power to see with remarkable clearness the customer of the market
 - *b* Power of leadership, the ability to inspire loyalty and enthusiasm in subordinates
 - *c* Judgment of men; the ability to pick subordinates of power.

2 Administrative ability, technique, the power to use tools—to do work through others.

These qualities are essential because large industries involve the use of large bodies of men who must be led and cannot be driven. They must be always kept growing, which requires vision of the changing conditions of the market; the promotion stage is never over.

I am not an engineer, but have known engineers and have lived with them, slept with them, have worked with them, and I admire them. They are great men, but as we train our engineers today, we handicap them as managers. If they are to be great managers, you have got to modify their training.

John H. Williams, consulting engineer, of Philadelphia, commented on the development by Mr. Leach of the need for the thoughtful type and by Mr. Cabot for the enthusiastic, and stated as his opinion that the need was for a man whose one great characteristic is flexibility. Mr. Williams in commenting on Mr. Cabot's analysis of the failure of the railroad men because of their responsibility without authority pointed out that an ability to enforce judgments peacefully was of greater value than authority.

Calvert Townley, vice-president of the Westinghouse Electric and Manufacturing Company, discussed the recent change in conception of an engineer's function. He pointed out that the reason for the growing demand for engineers is because engineering training leads to the search for facts and conclusions based on these facts. The engineer attacks the problem from the quantitative rather than the qualitative point of view. Mr. Townley stated as his opinion that the position of the railroads today is due to the former promoters whose broad vision was not bounded by facts and figures.

Lewis H. Nash expressed his approval of the discussion of finance by engineers. He emphasized the importance of a knowledge of finance by the engineer as the primary part of any enterprise. Inasmuch as the engineer is by education particularly fitted to look upon an enterprise from the point of view of efficiency, it is his duty to see that the best materials and the best devices are selected for the purposes desired and that the costs are reasonable. It is his duty to supervise the handling and distribution costs. From his point of view finance is one of the tools to be used and the engineer is by education and temperament particularly fitted to have charge of the finance of an honest enterprise.

Abraham Korminsky and Blamey Stevens emphasized the important function of the engineer in straightening out the kinks in present condition of affairs, not only by developing proper effectiveness of our industries but also by taking part in the careful analysis of general business conditions.

NEWS OF OTHER SOCIETIES

National Safety Council

According to figures contained in resolutions adopted by the National Safety Council at the Tenth Annual Safety Congress, held in Boston, Mass., Sept. 26, some 80,000 accidental deaths and millions of injuries occur annually. National experience has demonstrated that 75 per cent of industrial accidents are preventable. Experimental campaigns in seven cities have resulted in the reduction of public accidents by 25 to 40 per cent and further efforts it is stated, will undoubtedly result in even greater progress. The direct economic cost of accidents in industry alone exceeds one billion dollars annually and greater indirect losses are caused by the curtailment of production and lowering of morale. The National Safety Council advocates the safeguarding of all dangerous machinery and places, the redesigning and reconstruction of factory equipment when necessary, the education of all workmen and their supervisors in safe methods and habits of work, safety education of school children and of college and university students, and the mobilization of all community forces for intensive and permanent campaigns against accidents of all types.

At a meeting of the Executive Committee of the Council, the organization of a Drop Forge Section and a Petroleum Section to conduct accident prevention in these industries was approved.

W. H. Cameron, formerly secretary-treasurer of the National Workmen Compensation Service Bureau, New York City, was elected executive secretary of the Council.

Society of Industrial Engineers

The fall convention of the Society of Industrial Engineers was held at Springfield, Mass., Oct. 5 to 7. The leading topic of the meeting was Industrial Stability, and sectional meetings dealt with the sub-topics of education, manufacturing and selling, financing and accounting, and industrial relations.

L. W. Wallace, president of the society, and executive secretary of The Federated American Engineering Societies, opened the meeting with a discussion of the chief causes of industrial unsettlement. F. M. Feiker, assistant to Secretary of Commerce Hoover, spoke of the need of a barometer of business analogous to the Weather Bureau. At an evening session the first day of the meeting, E. St. Elmo Lewis, of New York, gave an interesting address on Setting Sales Standards.

Among the speakers on the second day were Dr. Ira N. Hollis, of Worcester Polytechnic Institute, on harmonious relations between factory owners, managements and employees; Arthur T. Davenport, of Sweet, Orr & Co., New York, on The Importance to the Factory of Constant Output, and Harry A. Hopf, organization counsel for the Federal Reserve Bank of New York, on Standardization of Salaries of Administrative Employees.

At a meeting on Friday afternoon Robert B. Wolf, of New York, discussed The Elimination of Waste in Industry by Standardization, and Frank B. Gilbreth, of Montclair, N. J., spoke on Standardization of the Task.

The speakers at the final session Friday evening were Reuben A. Lundquist, chief of the electrical division of the Federal Department of Commerce, who dealt with The Influence of Foreign Trade on Industrial Stability, and Floyd Parsons, of Philadelphia, who discussed the education of the public for industrial stability.

Inspection trips were made to the principal manufacturing plants of Springfield and vicinity.

Officers of the Society for 1922 were elected as follows: President, Joseph W. Roe, head of the industrial engineering department of New York University; treasurer, F. C. Schwedtman, vice-president National City Bank, New York; secretary, W. G. Sheehan, Detroit; and business manager, George C. Dent, Chicago.

American Gear Manufacturers' Association

At the semi-annual meeting of the American Gear Manufacturers' Association held at Rochester, N. Y., Oct. 13, 14, and 15, reports of committees carrying on special investigations were heard and discussed, some standards were adopted as recommended practices, and definite steps were taken by committees toward coöperative work with standardization bodies of such organizations as the American Society for Testing Materials, The American Society of Mechanical Engineers, and the Society of Automotive Engineers, all of which organizations are working under the Rules of the American Engineering Standards Committee. Sessions at which committee reports were presented were opened with the reading of papers, the majority of which dealt with gear-making problems. Among the speakers were S. O. White, chief engineer of the Warner Gear Co., Muncie, Ind., R. W. Daniels of the Baush Machine Tool Co., Springfield, Mass., and E. W. Miller, chief engineer of the Fellows Gear Shaper Co., Springfield, Vt. E. S. Sawtelle, assistant general manager of the Tool Steel Gear & Pinion Co., Cincinnati, told of his experiences and observations in a recent European trip.

The results of a questionnaire sent to the membership by the Committee on Uniform Cost Accounting are of interest. Nearly 55 per sent of the 44 companies replying stated that they were in favor of the committee's classification of accounts. The machine-hour rate of distributing the factory overhead expenses is employed by 16 of the companies and one percentage of direct labor for the entire plant is in use in 14 companies. In the distribution of administrative, general and selling expenses to costs apply a percentage of the factory costs while seven combine these expenses with the shop overhead and make the distribution as a percentage if the direct labor. The committee is of the opinion that the shop overhead expenses should be distributed to machines, groups of machines or manufacturing departments and that such expenses as special tools and patterns should be charged direct to the job for which they are made or purchased. The committee recommended that commercial expenses be distributed on a percentage of factory cost basis.

The report of the Herringbone Gear Sub-Committee on a recommended practice providing for tooth calculation on the basis of diametral pitch in the plane of rotation was approved. However, it is not likely that this practice will be broadly followed until the committee has submitted recommendations to make it possible for gear makers to use certain standard stock hobs in cutting according to the new standard.

An interesting feature of the meeting was an inspection trip to the Gleason Works, where a number of new machines were seen in operation.

National Machine Tool Builders' Association

The National Machine Tool Builders' Association held its annual meeting in New York City, October 18, 19 and 20. In his report August H. Tuechter, president, reviewed the history of the association, and discussed the general lines of work which he believed it should follow.

The report of the general manager, Ernest F. DuBrul, dealt with association activities in general, with particular reference to statistical service, giving suggestions for the improvement of the business-barometer charts which the association has been issuing every month.

Mr. DuBrul, Prof. David F. Jordan of New York University, and C. L. Cameron of Gould & Eberhardt, Newark, N. J., discussed business cycles, especially as affecting machine-tool builders. Hon. Charles L. Underhill, congressman from Massachusetts, spoke on the subject of How Present Political Policies Affect Business.

W. H. Rastall, chief of the Industrial Machinery Division, U. S. Dept. of Commerce, and J. H. Drury, treasurer, Union Twist Drill Co., Athol, Mass., told of the conditions in the machine-tool industry in the Orient and in Europe, respectively. J. E. Andress, secretary, Barnes Drill Co., Rockford, Ill., discussed the granting of long-term credit with proper guarantees or insurance in foreign trade.

H. L. Flather, treasurer, Flather & Co., Inc., Nashua, N. H., discussed the possibility of utilizing machine-tool plants during slack times, and E. M. Brotherhood, vice-president, Manning, Maxwell & Moore, Inc., New York, expressed his opinion on the possibilities of reduction in the cost of machine tools in 1922.

Mr. Teuchter will continue to serve as president, and Mr. DuBrul as general manager; H. W. Dunbar, sales manager, the Norton Company, Worcester, Mass., was elected secretary to succeed Carl F. Dietz, resigned. The next Spring Convention will be held at Atlantic City.

Economics of Bridgework

Economics of Bridgework. By Dr. J. A. L. Waddell, John Wiley & Sons, Inc., New York, 1921. Cloth, 6×9 in. 512 pp., illus., $6.

Although written primarily for bridge specialists, as the author informs us, this book is not unworthy of some consideration by the mechanical engineer, for of the forty-five chapters at least twelve are of wider application than may have been intended in their conception. Economics of Bridgework may be read with profit by the electrical and mechanical as well as the civil engineer.

There is much food for thought and doubtless for experimentation in the chapter on alloy steels. Some of the data given seem fairly well substantiated, others are more or less problematical and require the corroboration of actual analysis.

The names chosen for some of the proposed alloys are weird to say the least, "chrovanmol," "nichro," etc., reminding one of the "Jabberwock" of Alice's Adventures; but if an alloy of chromium vanadium and molybdenum can be commercially produced to develop without heat treatment and without excessive cost, the characteristics assigned to it by the author, among them 170,000 lb. elastic limit, it should make great changes in the weights of engineering structures, and we can forgive it its name.

As the author himself says, his chapter dealing with the economics of operating machinery and power is "limited to a dissertation covering general conditions and the offering of a few pertinent suggestions." Among the latter a few are particularly worthy of note.

The author highly recommends as his ideal apparatus "two high-speed gas engines each with hydraulic transmission gear and worm gear, the two engines together sufficient to operate the bridge at maximum required speed, and one alone (by means of the hydraulic reducing gear) capable of running it at a slower speed." It would appear that there should be a field for such apparatus but that the use of the worm drive should be limited to fairly small units, operating at sufficiently high speed to allow of a reasonably efficient worm design. Where electric power is not available, the gas engine seems to offer the best source of power, but the control features possible with the former, such as limit switches, interlocks, etc., while perhaps not impossible with the latter, are certainly not so elastic of application or so practicable.

In closing his chapter on Economics of Operating Machinery, the author justly criticises a practice among engineers of covering the design of the machinery for movable bridges by a general specification not necessarily applicable to the specific case in hand, thus producing mechanism far too heavy for actual needs. He refers to the requirement that brakes on bascule spans be designed to resist a wind of fifteen or twenty pounds per square foot on the area of the open leaf in cases where no such condition is at all likely to exist due to protection from surrounding hills, and without any allowance for increase in unit stresses for such a condition. This point is certainly very well taken.

The book is full of good suggestions and is a fitting supplement to the author's monumental work, Bridge Engineering.—H. P. Van C.

Analytical Mechanics for Engineers. By Fred B. Seely and Newton E. Ensign. John Wiley & Sons, Inc., New York, 1921. Cloth, 6 × 9 in., 486 pp., diagrams, $4.

The aim in this book has been to make the principles of mechanics stand out clearly, to build them up as much as possible from common experience, to apply the principles to concrete problems of practical value, and to emphasize the physical rather than the mathematical interpretation of them. Statics, kinematics and kinetics are included, the two latter being developed with regard for the increasing importance of dynamics to engineers. The treatment of kinetics, while extensive, has been restricted to the more common types of motion found in engineering practice.

Berichte Und Abhandlungen der Wissenschaftlichen Gesellschaft Fur Luftfahrt. (Beihefte zur "Zeitschrift Flugtechnik und Motorluftschiffahrt.") R. Oldenbourg, Munich, 1921. Paper, 9 × 12 in., 81 pp., illus., 32 marks.

This supplement contains the proceedings of the sixth meeting of the Society, at Charlottenburg, October 15, 1920. In addition to the official actions of the meeting, it contains the technical papers presented, which treat of the relation between the design of power plants for aircraft and safety in flight. The results of research in aerology and atmospheric electricity by flights, the formation of eddies by planes and advances in space telegraphy and telephony.

Chemical and Metallographic Examination of Iron, Steel and Brass. By William T. Hall and Robert S. Williams. First edition McGraw-Hill Book Co., Inc., New York, 1921. Cloth, 5 × 8 in. 501 pp., illus., $5.

This work is divided into two parts. The first gives a careful selection of methods for the chemical analysis of iron and steel, brass and bronze. Special attention is given to explanation of the chemical reactions involved in the methods given and to the discussion of their accuracy. Emphasis is placed on those that are both accurate and rapid. Part two considers the physical inspection of metals. In it the methods for preparing and examining polished surfaces are described. A brief introduction to metallography, as applied to the inspection of alloys, is included.

Drawing Room Practice. By Frank A. Stanley. First edition. McGraw-Hill Book Co., Inc., New York, 1921. Cloth, 6 × 9 in., 253 pp., illus., $2.50.

This book deals with the making of drawings, from the simplest constructions to complete assembly and working drawings of various classes. It is based on experience in a number of leading American and European drawing rooms, and in teaching students. The difficulty in visualizing the work represented by a drawing, which many students undergo, has led the author to present photographs of the objects represented by the working drawings discussed in the book.

Economic Aspects of the Great Lakes-St. Lawrence Ship Channel, By Roy S. MacElwee, Alfred H. Ritter. The Ronald Press Co.. New York, 1921. Cloth, 6×9 in., 291 pp., maps, tables, $4.

This work is a study of the local and national advantages to be gained from opening the Great Lakes to ocean traffic. It attempts to coördinate the information on the commercial and economic aspects of the proposed ship channel, as presented at the hearings held throughout the country by the International Joint Commission and to present the vital facts affecting the advisability of the construction of the proposed improvement.

Grinding Machines and Their Use. By Thos. R. Shaw. Sir Isaac Pitman & Sons, Ltd., London and New York, 1921. (Technical primer series.) Cloth, 4×6 in., 114 pp., illus., $0.85.

A concise review of the main principles of workshop precision grinding, based on long experience in the design and construction of grinding machines and close observation of their utility. Suitable as an introduction to the subject.

Manhood of Humanity. By Alfred Korzybski. E. P. Dutton & Co., New York, 1921. Cloth, 6 × 8 in., 264 pp., $3.

This book is primarily a study of man and ultimately embraces all the great qualities and problems of man. The author approaches the problem from a mathematical, an engineering, point of view, with the object of ascertaining what man's real nature is and what the basic laws of his nature are, and hopes thus to point the way to a science of directing human energies and capacities to the advancement of human welfare.

The Mechanical Production of Cold. By Sir J. A. Ewing. Second edition. University Press, Cambridge, 1921. Cloth, 6 × 9 in., 204 pp., diagrams, $8. (Gift of The Macmillan Co., N. Y.)

This book contains the "Howard" Lectures delivered before the Society of Arts in 1897, as revised and reprinted in 1908. It provides a general account of refrigeration, in which stress is laid on the thermodynamic aspect of the subject, and an attempt is made to render this aspect intelligible without unnecessary mathematics.

The changes in this edition are the correction of certain errata and the clearing up of some obscure points.

Mechanics. By James E. Boyd. First edition. McGraw-Hill Book Co., Inc., New York, 1921. Cloth, 6 × 9 in., 417 pp., diagrms., $3.50

Intended to give a working knowledge of the principles of mechanics and to supply a foundation upon which intelligent study of the strength of materials, stresses in structures, machine design and other more technical courses may rest. In the development of the subject, emphasis is put upon the physical character of the ideas expressed.

Mechanism. By Robert McArdle. McGraw-Hill Book Co., Inc., New York, 1921. Cloth, 6 × 9 in., 173 pp., illus., diagrms., $2.25.

A brief course for students of engineering. Commences with a short discussion of motions and velocities, which is followed by a study of linkages, cams, gearing, belting and intermittent motions. In this revision difficult points have been made clearer and many problems have been added.

Modern Building Superintendence and the Writing of Specifications. By David B. Emerson. Charles Scribner's Sons, New York, 1921. Cloth, 4 × 7 in., 247 pp., $1.75.

This volume is intended to aid the young engineer in superintending construction and in writing building specifications. The author outlines, step by step, the duties of the superintendent during the erection of a typical modern twenty-story office building, calling attention to the matters that must be watched. In similar fashion, he outlines the proper procedure in writing specifications for a small dwelling.

Modern Central Stations. By Charles W. Marshall. Sir Isaac Pitman & Sons, Ltd., London and New York, 1921. (Technical primer series.) Cloth, 4 × 6 in., 115 pp., illus., $0.85.

A brief description of the principal features of British central-station practice, intended for young engineers. Includes the coal- and ash-handling plant, boiler house, engine room, switch and protective gear, plant operation and testing.

Oil Flow in Pipe Lines. By R. S. Danforth. King Knight Co., San Francisco, 1921. Paper, 9 × 12 in., 12 pp., charts, $3.

These charts have been compiled to facilitate the solution of problems in oil pumping. They are derived from the formulas and method of computation used by the author in his monograph entitled Friction Losses in Oil Pipe Lines and are based on the law of the flow of liquids in pipe lines deduced at the National Physical Laboratory of Great Britain. The charts will apply to the flow of any liquid or gas in cases where the inside surface of the pipe is of the roughness ordinarily found in oil-pipe lines.

The Orifice Meter and Gas Measurement. By Willis C. Brown and Malcolm B. Hall. The Foxboro Co., Inc., Foxboro, Mass., 1921, Cloth 5 × 8 in., 112 pp., tables, illus., $3.50.

This book, published by the manufactures of the first commercial orifice meter, gives authentic information on orifice coefficients and their derivation, together with complete details of the mechanical construction of their own meter.

Power House Design. By Sir John F. C. Snell. Second edition. Longmans, Green & Co., New York, 1921. (Electrical engineering series.) Cloth, 6 × 9 in., 535 pp., illus., diagrams, tables, $14.

In preparing this book, the author has drawn upon his own experience of over twenty years and has collected and classified the experience of other engineers. The information thus acquired has been carefully sifted and condensed in the present volume, which the writer believes to contain all the requisite practical information on its subject. The principles and information given cover the design and equipment of central stations and isolated plants for supplying light and power to cities, factories, mines, railroads, etc., and are accompanied by typical examples of modern installations. This edition has been thoroughly revised and to a considerable extent rewritten

Pneumatic Conveying. By E. G. Phillips. Sir Isaac Pitman & Sons, Ltd., London and New York, 1921. (Technical primer series.) Cloth, 4 × 6 in., 108 pp., illus., $0.85.

A general survey of the information available on machinery and methods form handling coal, ashes, grain and other heavy solids, with brief references to air-lift pumping, vacuum cleaning, etc.

Wirtschaftliches Schleifen. Compiled by G. Schlesinger. Julius Springer, Berlin, 1921. Paper, 9 × 12 in., 103 pp., illus., 24 M.

A collection of essays on grinding machines and processes, based on German and American shop practice, and intended to call attention to the advantages of grinding, its use for various purposes, the machines employed, and the methods used. The articles first appeared in Vols. 11 to 15 of *Werkstattstechnik*.

Industrial Relations Conference

An industrial relations conference was held at Harrisburg, Pa., Oct. 24–27, under the auspices of the Pennsylvania State Department of Labor. Among the speakers were L. W. Wallace, executive secretary of American Engineering Council, representing The Federated American Engineering Societies, who discussed industrial waste from the standpoint of unemployment, and Dr. John M. Thomas, president of Pennsylvania State College, who dealt with industrial education in college and university.

Industrial Relations Association of America

The annual convention of the Industrial Relations Association of America was held in New York City November 1–4, 1921. During the first three days there were a number of important round-table discussions, and sectional meetings dealing with some of the problems of the various industries in handling personnel. Business conditions, the basic principles of sound employment practice, department costs, fundamental principles of human relations in industry, unemployment, essential labor statistics and their uses, and determination of wage rates were among subjects discussed at other sessions. Magnus W. Alexander, managing director of the National Industrial Conference Board, George E. Roberts, vice-president of the National City Bank, W. H. Nichols, Jr., president of the General Chemical Company, C. R. Dooley and C. J. Hicks, of the Standard Oil Company, E. B. Merriam, director of industrial relations of the General Electric Company, and Loyall A. Osborne, president of the Westinghouse Electric Company, were among the speakers at these sessions.

The last two days of the convention were held in conjunction with the Academy of Political Science. There were five main sessions, three on Nov. 4 and two on Nov. 5. The first two considered the subjects of personnel work and coöperation within industrial plants and industry-wide coöperation.

One of the most important of these joint sessions was that held on Friday evening, Nov. 4, dealing with good-will and coöperation in industry. The presiding officer was Herbert Hoover, who called attention to the growing tendency on the part of the public to demand that its interests be heard in the settlement of strikes, and emphasized the importance of making such demands in a way which will secure good-will as well as justice. B. Seebohm Rowntree, York, England, discussed conditions essential to industrial coöperation from a British employer's point of view, while Hugh Frayne, general organizer, American Federation of Labor, dealt with the worker's point of view. Industrial coöperation in Canada was the subject of an address by Hon. G. C. Robertson, Minister of Labor, Ottawa, Canada. Secretary of Labor Davis, in an address on government counselors and efforts to promote coöperation, stated as his belief that the living wage was not enough and that the country is benefited if its workmen are able to save.

The two sessions on Nov. 5 covered industrial relations in governmental employment and in financial institutions, and governmental and other organized counsel for the better promotion of industrial relations. Personnel work in the Post Office Department, Rock Island Arsenal, prisons and state institutions, Federal Civil Service, and financial institutions were considered at the first of these sessions. At the second, Alexander C. Brown, president of the Brown Hoisting Machinery Co., Cleveland, and president of Cleveland Chamber of Commerce, discussed the part of the chamber of commerce in promoting better industrial relations, and D. S. Kimball, dean of the College of Engineering, Cornell University, president-elect, A.S.M.E., the part of the universities and technical schools. Other speakers outlined specific work being carried on in Philadelphia and New York.

THE ENGINEERING INDEX

(Registered U. S. Patent Office and Canadian Patent Office.)

THE ENGINEERING INDEX presents each month, in conveniently classified form, items descriptive of the articles appearing in the current issues of the world's engineering and scientific press of particular interest to mechanical engineers. At the end of the year the monthly installments are combined along with items dealing with civil, electrical, mining and other branches of engineering, and published in book form, this annual volume having regularly appeared since 1906. In the preparation of the Index by the engineering staff of The American Society of Mechanical Engineers some 1200 technical publications received by the Engineering Societies Library (New York) are regularly reviewed, thus bringing the great resources of that library to the entire engineering profession.

Photostatic copies (white printing on a black background) of any of the articles listed in the Index may be obtained at a price of 25 cents per page, plus postage. A separate print is required for each page of the larger periodicals, but wherever possible two small or medium-sized pages will be photographed together on the same print. The bill will be mailed with the print. When ordering photostats identify the article by quoting from the Index item: (1) Title of article; (2) Name of periodical in which it appeared; (3) Volume, number, and date of publication of periodical; (4) Page numbers. Orders should be sent to the Engineering Societies Library, 29 West 39th Street, New York.

ABRASIVE WHEELS

Selection and Grading. Grinding Wheels, James Shaddock and Alfred Herbert. Eng. Production, vol. 3, no. 48, Sept. 1, 1921, pp. 198–200, 2 figs. Notes on selection and grading. Gives list of wheels suitable for use on Norton machines for external grinding, and on Heald machines for internal grinding.

ACCOUNTING

Power Plants. Power-Plant Accounts—I, II, III, IV and V, Wilfred E. Miller. Power, vol. 54, nos. 11, 12, 13, 14 and 15, Sept. 13, 20, 27, Oct. 4 and 11, 1921, pp. 408–410, 448–451, 489–491, 528–530 and 558–560, 13 figs., Sept. 13: Tells what accounting is and shows how to keep records of labor, fuel, water, lubricants, ash removal, repairs, scale removal, etc. Sept. 20 and 27: Use of journal and ledger. Oct. 4 and 11: Indirect expense.

AERODYNAMICS

Air-Flow Theory. Recent Progress in the Aerodynamic Air-Flow Theory (Die neueren Fortschritte der flugtechnischen Strömungslehre), L. Prandtl. Zeit. des Vereines deutscher Ingenieure, vol. 65, no. 37, Sept. 10, 1921, pp. 959–965, 16 figs. Notes on recent development of hydrodynamic theory of air resistance. Points out that Newton theory is not in accordance with actual behavior. Motion of air resembles that of a volumetrically constant liquid. Most important laws for such flows are presented, and their application to airship bodies and airplane surfaces explained. Tests are said to confirm results of investigation.

AERONAUTICS

Technical Problems. Some Technical Problems in Aeronautics. Mech. Eng., vol. 43, no. 8, Aug. 1921, pp. 526–528 and 562, 8 figs. Aluminum cylinder castings, air-cooled airplane engines, airplane carburetors and radiators, aerial photography, machine-gun synchronizers, etc., as discussed at joint visit of Am. Soc. Mech. Engrs. and Soc. Automotive Engrs. to McCook Field.

AEROPLANE ENGINES

Benz. The 300-hp. Benz Aircraft Engine, A. Heller. Flight, vol. 13, no. 32, August 11, 1921, pp. 537–542, 34 figs. Describes in detail latest type made by Benz & Co. Engine has 12 cylinders of 135 mm. bore and 150 mm. stroke. Trans. from Zeit. des Vereines Deutscher Ingenieure.

Comparative Data. Comparative Aircraft Engine Data. Automotive Industries, vol. 45, no. 10, Sept. 8, 1921, p. 457. Gives figures as to power of engines, compression ratio, fuel consumption, mean effective pressures, weight per hp. working stresses, etc. From La Technique Moderne.

Laboratory, Testing. A Laboratory for Aircraft Engine Testing, Herbert Chase. Automotive Industries, vol. 45, no. 11, Sept. 15, 1921, pp. 520–522, 3 figs. Describes laboratory of Wright Aeronautical Corp. and their facilities for testing engines.

Types. Aero Engines, Alan E. L. Chorlton. Jl. Roy. Soc. Arts, vol. 69, no. 3589, Sept. 2, 1921, pp. 689–705, 17 figs. Discusses various types of engines and gives tables of test data of leading engines in 1914, both British war office trials and German aeroplane engine trials.

AEROPLANES

Balancing. The Design of Aeroplane Control Surfaces, with Special Reference to Balancing, H. B. Irving. Aeronautical Jl., vol. 25, no. 130, Oct. 1921, pp. 537–555, 13 figs. Discusses three methods of balancing, all of which have been adopted in varying measure in practice: The "horn" method; "backward hinge" method; and Avro patent method.

Barnhart Twin 15. The Barnhart Twin 15 "Wampus-Kat." Aviation, vol. 11, no. 11, Sept. 2, 1921, pp. 309–311, 2 figs. Airplane built by C. R. Little; 180 hp.; gives data and describes principal features.

Bristol 10-Seater. The "Bristol" Ten-Seater Airplane. Aviation, vol. 11, no. 8, August 22, 1921, pp. 229, 1 fig. Gives dimensions, weights, loading and performance data; 450-hp. Napier engine.

Commercial. The Commercial Airplane, L. B. Lent. Aviation, vol. 11, no. 7, August 15, 1921, pp. 188–189. Discusses speed, carrying capacity, distribution of load, etc.

Handley-Page. The Handley-Page Airplane V/1500 (Das Handley Page-Flugzeug V/1500). Motorwagen, vol. 24, no. 23, Aug. 20, 1921, pp. 474–476, 3 figs. Discusses its salient features and compares it with German machines of similar type.

Helicopters. See HELICOPTERS.

Landing. The Manoeuvres of Getting Off and Landing, R. M. Hill. Aeronautical Jl., vol. 25, no. 130, Oct. 1921, pp. 510–536, 2 figs. Discusses factors influencing getting off and landing, and experiments with mechanical devices to assist landing, such as the Palethorpe tail skid and the Noakes ground indicator.

Safety Factors in Design. Safety Factors in Airplane Design, Alfred S. Niles. Eng. News-Rec., vol. 87, no. 12, Sept. 22, 1921, pp. 490–491. Reasons for adoption of low factors based on abnormal conditions. Successful use of long columns.

Single-Engined Cabin. Single-Engined Cabin Airplanes, Donald W. McIlhiney. Aviation, vol. 11, no. 13, Sept. 26, 1921, pp. 364–365, 1 fig. Includes table giving data concerning forty-two machines of this type.

Struts. Non-Injurious Ultimate-Strength Tests for Interplane Struts, E. R. Maurer. Jl. Soc. Automotive Engrs., vol. 9, no. 3, Sept. 1921, pp. 201–207, 10 figs. Describes direct test by subjecting the strut to ordinary test for maximum load, and indirect test, consisting in making a simple bending test for certain data.

Zeppelin-Staaken. The Monoplane "Zeppelin-Staaken" (Le Monoplan "Zeppelin-Staaken"), E.-H. Lemonon. L'Aerophile, vol. 29, no. 13–14, July 1–15, 1921, pp. 203–208, 12 figs. Gives data of dimensions and tests and describes main features; has 4 Mayhach 290-hp. engines.

AIRCRAFT

High-Altitude. High Altitude Aircraft of the Future, C. Eberhardt. Automotive Ind., vol. 45, no. 9, Sept. 1, 1921, pp. 418–420, 3 figs. Discusses possibility of keeping engine output constant at high altitudes. Translated from Der Motorwagen.

AIRCRAFT CONSTRUCTION MATERIALS

Plywood. Making Plywood in South Africa. So. African Jl. of Industries, vol. 4, no. 7, August 1921, pp. 613–618, 5 figs. Discusses preparation of logs, peeling process, gluing of sheets, uses of plywood, etc.

AIRSHIPS

Transatlantic. Airships for a Transatlantic Service, Ralph Upson. Aviation, vol. 11, no. 13, Sept. 26, 1921, pp. 374–376, 1 fig. Discusses advantages and disadvantages and works out average flying data for New York-London routes.

ALCOHOL

Corncobs as Source. A Fermentation Process for the Production of Acetone, Alcohol, and Volatile Acids from Corncobs, W. H. Petersan, E. B. Fred and J. H. Verhulst. Jl. Industrial & Eng. Chem., vol. 13, no. 9, Sept. 1921, pp. 757–759. Concludes that corncobs may be utilized to produce acetone, ethyl alcohol, formic acid, and acetic acid, by fermenting a syrup made from corncobs by hydrolysis with dilute sulphuric acid.

Fuel. Alcohol as a Combustion Fuel, E. C. Freeland and W. G. Harry. Sugar, vol. 23, no. 9, Sept. 1921, pp. 474–476. Concludes that alcohol is destined to supplant gasoline. (Continuation of serial.)

Molasses as Source. Use of Alcohol Made From Final Molasses As Motor Power in Cuba, R. G. Tillery. La. Planter & Sugar Manufacturer, vol. 67, no. 9, August 27, 1921, pp. 142–143.

ALIGNMENT CHARTS

Principles and Uses. The Alignment Chart, C. W. Crockett. Automotive Industries, vol. 45, no. 13, Sept. 29, 1921, pp. 614–618, 5 figs. Exposition of principles underlying construction of alignment charts. Used for graphical representation of many mathematical relations.

ALLOY STEEL

Heat Treatment. Three Types of Alloy Sheet Steel—II and III, Horace C. Knerr. Iron Age, vol. 108, nos. 11 and 12, Sept. 15 and 22, 1921, pp. 655–658 and 725–728, 7 figs. Sept. 15: Details of heat treatment necessary to attain highest tensile strength; hardness and other data. Sept. 22: Electric and acetylene welding details and their effect on physical properties; chrome-vanadium steel adopted.

ALLOYS

Metamorphosis. Metamorphosis in Metal Alloys (Ueber Umwandlungen an Metallegierungen), F. Hauser. Zeit. für Physik, vol. 5, no. 4, June 23, 1921, pp. 220–226, 7 figs. Writer has succeeded in following process of transformation, occurring in certain metals and alloys after congealing, under a metal microscope and of making photographic reproductions thereof.

Physical Properties. Thermal, Electrical and Magnetic Properties of Alloys, Alpheus W. Smith. Jl. Franklin Inst., vol. 192, nos. 1 and 2, July and Aug. 1921, pp. 69–105 and 157–202, 57 figs. Deals with metals insoluble in each other, completely soluble in each other, with limited solubility in each other, and forming compounds with each other. Notes on change of thermoelectromotive force with temperature; theories of resistance and thermoelectric forces, and resistance and hardness.

White-Metal Bearings. White Metal Bearing Alloys, John R. Freeman, Jr. and R. W. Woodward. Metal Ind., vol. 19, no. 9, August 26, 1921, pp. 149–

Western (West.)

152, 3 figs. Discusses design of new apparatus and results of tests to determine mechanical properties in compression and Brinell hardness at elevated temperatures. Technologic paper Bur. Standards, No. 188.

[See also ALUMINUM ALLOYS; BEARING METALS; BRASS; BRONZES; COPPER ALLOYS; MAGNESIUM ALLOYS; NICKEL ALLOYS; ZINC ALLOYS.]

ALUMINUM

Castings. Aluminum Casting, F. A. Livermore. Brass Wld., vol. 17, no. 8, August 1921, pp. 231–233. Discusses hardness and composition of alloys, also welding aluminum.

Uses. Aluminum and Its Uses (L'aluminium et ses applications), Sigma. La Metallurgie, vol. 53, nos. 35 and 36, Sept. 1 and 8, 1921, pp. 1663–1664 and 1701–1702. Discusses its properties and application in aeronautics. (Concluded.)

ALUMINUM ALLOYS

Aluminum-Copper. Aluminum-Copper Alloys, Robert J. Anderson. Am. Electrochemical Soc. advance paper no. 16, for Meeting, Sept. 29–Oct. 1, 1921, pp. 207–236, 1 fig. General information with regard to manufacture, properties, and uses of commercial aluminum-copper alloys employed in United States. Bibliography.

Aluminum-Magnesium-Silicon. The Constitution and Age-Hardening of the Alloys of Aluminium with Magnesium and Silicon, D. Hanson and Marie L. V. Gayler. Inst. Metals advance paper for meeting Sept. 21–22, 1921, no. 10, 35 pp., 47 figs. Results of investigation, summarized in diagrams, are said to leave little doubt that ageing of these alloys is due to fact that, on quenching, magnesium and silicon are retained, probably in solution, in an unstable condition, from which they tend to revert to a more stable form.

Iron-Pot Melting. Iron-Pot Melting Practice for Aluminum Alloys—IV, Robert J. Anderson. Metal Ind. (N. Y.), vol. 19, no. 9, Sept. 1921, pp. 360–362, 2 figs. Discusses size and capacity of furnaces, furnace linings and their life. (To be continued.)

Production. Experiments in the Production of Alloys for Aluminium Sheets, W. Schulte. Metal Ind. (Lond.), vol. 19, no. 8, August 19, 1921, pp. 131–134. Gives physical properties of a large number of alloys of different composition. Translated from Die Metallbörse.

AUTOGENOUS WELDING

Copper. Autogenous Copper Welding (Autogene Kupferschweissungen), Adolf Bothe. Betrieb, vol. 3, no. 22, Aug. 13, 1921, pp. 689–693, 6 figs. Describes how new or damaged copper engine or boiler parts, even when highly stressed, can be joined together or repaired through autogenous welding, quickly and durably, and with minimum cost.

Autogenous Welding of Copper Locomotive Fireboxes (Autogenschweissung von kupfernen Lokomotivfeuerbüchsen), H. Weese. Zeit. des Vereines deutscher Ingenieure, vol. 65, no. 36, Sept. 3, 1921, pp. 945–947, 11 figs. Account of work done in main railway shop in Magdeburg-Buckbau, Germany. Advantages of welding work which can be carried out in short time and without detachment of boiler. Experiences with oxy-acetylene welding. Success of different welding operations.

AUTOMOBILE ENGINES

Crankshafts. The Rolls-Royce Crankshaft, Fred H. Colvin. Am. Mach., vol. 55, no. 12, Sept. 22, 1921, pp. 453–454, 4 figs. Main bearings rough turned, crankpins ground from the rough. Finishing completed unit of crankshaft, flywheel and clutch ring.

Jordan. Important Changes Feature the New Jordan Model, J. Edward Schipper. Automotive Industries, vol. 45, no. 14, Oct. 6, 1921, pp. 654–657, 7 figs. New design of Jordan engine, incorporating chain drive and hollow shaft lubrication. Exposed metal parts are rustproofed.

Machining. Machining Motor-car Engine Flywheels. Machinery (Lond.), vol. 18, no. 465, August 25, 1921, pp. 641–645, 13 figs. Use of vertical automatic lathes for finishing all surfaces at two settings of work.

Pistons. Manufacturing Automobile Pistons in a Jobbing Shop, Robert Mawson. Am. Mach., vol. 55, no. 13, Sept. 29, 1921, pp. 493–496, 11 figs. Manufacturing on small scale made possible in job shop by use of simple tools and fixtures.

AUTOMOBILE FUELS

Alcohol. Production of 95–97 per cent Alcohol for Motor Fuel. Int. Sugar Jl., vol. 23, no. 273, Sept. 1921, pp. 513–516, 1 fig. Describes improved triple column continuous still made by Blair, Campbell & McLean of Glasgow for production of Natilite.

See also ALCOHOL.

Producer Gas. Producer Gas as a Fuel for Automotive Vehicles, P. M. Heldt. Automotive Industries, vol. 45, nos. 10 and 11, Sept. 8 and 15, 1921, pp. 461–464 and 507–511, 7 figs. Discusses theoretical and practical aspect of possibility of operating truck or similar internal-combustion engines on gas derived directly from coal. Describes three British systems and their method of operation.

[See also GASOLINE.]

AUTOMOBILES

Air-Propeller-Driven. Air Screw Drive for Cars, W. F. Bradley. Autocar, vol. 47, no. 1351, Sept. 10, 1921, pp. 448–449, 4 figs. Describes recent developments with wind cars in Paris.

Australian Use. A Car Especially Designed for Use in Australia. Automotive Ind., vol. 45, no. 9, Sept. 1, 1921, pp. 409–410, 3 figs. Designed to meet tropical climate and adverse road conditions.

Horstman. The 10.5 Hp. Horstman Chasis. Automobile Engr., vol. 11, no. 153, August 1921, pp. 273–277, 13 figs. Original detail design and full cantilever springing fore and aft.

Hudson. Refinements in Control Characterize the New Hudson, J. Edward Schipper. Automotive Industries, vol. 45, no. 13, Sept. 29, 1921, pp. 604–606, 8 figs. Clutch and brake controls and steering gear have been redesigned to facilitate ease in handling; carbureter air is preheated.

G. Irat. The G. Irat Car (La voiture G. Irat), A. Contet. La Vie Automobile, vol. 17, no. 763, August 25, 1921, pp. 293–295, 6 figs. Designed for greatest economy without sacrificing speed. Four cylinder engine 70 × 130.

Interaction of Wheels, Springs and Roads. Holding The Road, J. L. Napier. Automobile Engr., vol. 11, no. 153, August 1921, pp. 266–272, 12 figs. Discussion of fundamental principles affecting interaction of wheels, springs and roads.

Machining Methods. Special Fixtures in the Peerless Shop. Am. Mach., vol. 55, no. 14, Oct. 6, 1921, pp. 549–550, 7 figs. Milling fixtures for continuous work; fixture for grinding ball ends; radius milling and threading; drilling connecting rods.

Plywood Bodies. Plywood as Material for Automobile Body Construction, Armin Elmendorf. Automotive Ind., vol. 45, no. 9, Sept. 1, 1921, pp. 414–417, 8 figs. Discusses waterproof glue development and advantages of plywood.

Rear-Axle Casing. Machining Rear Axle Casings. Machinery (Lond.), vol. 18, no. 470, Sept. 29, 1921, pp. 781–786, 11 figs. Discusses methods of machining a malleable iron casting for motor rear-axle casing. Production costs.

Rear-Axle Housing. Machining Two Peerless Rear-Axle Parts, Fred H. Colvin. Am. Mach., vol. 55, no. 13, Sept. 29, 1921, pp. 510–512, 9 figs. Notes on machining and assembly of rear-axle housing; fixtures used in production brake spider.

Repairing Methods and Equipment. Automotive Service Methods and Equipment, Howard Campbell. Am. Mach., vol. 55, no. 16, Oct. 20, 1921, pp. 619–623, 11 figs. Tools and methods used at New York Packard service plant, including testing fixtures, special reamers and other tools. "Maximum estimate" system.

Rhode Light Car. The Rhode Light Car. Auto, vol. 26, no. 37, Sept. 15, 1921, pp. 797–800, 11 figs. A 10-hp. car built by Mebes & Mebes, London, W. Describes engine (four-cylinder monoblock type with overhead valves inverted in detachable bead), transmission, suspension, and equipment.

Rover Runabout. Engineering Features of a Popular British Runabout, M. W. Bourdon. Automotive Ind., vol. 45, no. 9, Sept. 1, 1921, pp. 404–406, 3 figs. Describes 8-hp. air-cooled Rover.

Shop Practice, Daimler. The Works of the Daimler Co., Ltd. Automobile Engr., vol. 11, no. 153, August 1921, pp. 285–290, 20 figs. Interesting examples of shop practice on special work, at Coventry, Eng.

Suspension. Acme Spring Suspension. Autocar, vol. 47, no. 1350, Sept. 3, 1921, pp. 427–428, 4 figs. Describes three cantilever spring system for insulation from rough shocks.

Suspensions for Automobiles (Le problème de la suspension des voitures automobiles), M. Broulhiet. Révue de l'Industrie Minérale, no. 17, Sept. 1, 1921, pp. 93–100, 7 figs. It is shown that perfection can be attained in this as well as in other parts of automobile. (Concluded.)

Wheels. The Production of Pressed Steel Wheels Is Successfully Accomplished, J. Edward Schipper. Automotive Industries, vol. 45, no. 14, Oct. 6, 1921, pp. 668–671, 9 figs. Describes the various operations required in fabricating Gier pressed steel disk wheel.

[See also CARBURETORS.]

AVIATION

Civil. Developing a Ground Organization for Civil Aviation—II, W. F. Bradley. Automotive Industries, vol. 45, no. 13, Sept. 29, 1921, pp. 622–626, 6 figs. Discusses commercial aviation in France based on system of government subsidies. Particulars of air traffic; diagrams of 1st, 2nd, 3rd and 4th class landing fields. (Concluded.)

European Air Routes. The European Air Traffic Network (Das europäische Luftverkehrsnetz), George P. Neumann. Verkehrstechnik, vol. 38, May-June, 1921, pp. 218–221, 1 fig. Includes map showing air routes already in operation and those for which preparations have been made.

Future Prospects. The Future of Aerial Transport in the Public Services (L'Avvenire dei Trasporti Aerei Nei Servizi Pubblici), Umberto Nobile. Giornale del Genio Civile, vol. 59, May 31, 1921, pp. 270–304, 1 fig. Discusses security of aeroplanes, aerotransports and dirigibles; regularity of service; cost of aerial transportation compared with other systems; replacing of aerial material; etc.

B

BALANCING

Unbalance, Static and Dynamic. Four Years of Balancing Practice, N. W. Akimoff. Shipbldg. & Shipg. Rec., vol. 18, no. 10, Sept. 8, 1921, pp. 311–314, 6 figs. Discusses static unbalance, dynamic unbalance, obstacles in the development of the art, etc. (From Jl. Am. Soc. Naval Engrs.)

BEARING METALS

Bronze. Bronze for Bearing Metal, E. T. Keenan. Power, vol. 54, no. 9, Aug. 30, 1921, pp. 322–323. States that satisfactory results for general use was obtained with alloy consisting of copper 75 per cent, lead 17 per cent, zinc 5 per cent, tin 3 per cent.

BEARINGS, BALL

Manufacture. Ball and Roller Bearing Manufacture —I, J. D. Scaife. Eng. Production, vol. 3, nos. 52, 53 and 54, Sept 29, Oct. 6 and 13, 1921, pp. 290–293, 314–319 and 340–343, 25 figs. Methods employed. Paper presented before Instn. Production Engrs. Oct. 13: Discussion.

The Ball Bearing: In The Making, Under Test, and on Service, Henry L. Heathcote. Mech. Wld., vol. 70, nos. 1808 and 1811, Aug. 26 and Sept. 16, 1921, pp. 159–161, 3 figs. and 220–222, 3 figs. (Continuation of serial.) Paper read before Instn. Automobile Engrs.

BEARINGS, ENGINE

Machine for Fitting. Lapping and Running-in Machine. Machinery (Lond.), vol. 18, no. 470, Sept. 29, 1921, pp. 791–793, 4 figs. Discusses running-in and lapping processes in connection with fitting automobile engine bearings.

BELTING

Quarter-Twist. On an Irregular Behavior of Ordinary Quarter Twist Belt and Its Prevention, Hosaku Iwaoka. Jl. Soc. Mech. Engrs. & Soc. Nav. Architects, Sept. 1921. (In Japanese.)

BLAST FURNACES

Crane Iron Works, Pa. New Blast Furnace of the Crane Iron Works, Richard Peters. Iron Age, vol. 108, no. 31, Sept. 29, 1921, pp. 814–817, 5 figs.; also Iron Trade Rev., vol. 69, no. 13, Sept. 29, 1921, pp. 803–806, 4 figs. Plant at Catasauqua, Pa., modernized. Coke is now used as fuel. New stack is designed to produce foundry, forge and basic iron from mixture of 65 per cent magnetite ore and 35 per cent non-bessemer Mesabi ore.

Crane Operation. Crane Operating Costs at Blast Furnaces, George L. Collord. Iron Age, vol. 108, no. 15, Oct. 13, 1921, pp. 935–936, 1 fig. Locomotive and ore-bridge cranes shown to save much money, compared with hand methods formerly used. Analyses of costs.

Design. Completes New 600-Ton Blast Furnace in Ten Months. Iron Trade Rev., vol. 69, no. 11, Sept. 15, 1921, pp. 688–693, 6 figs.; also Iron Age, vol. 108, no. 11, Sept. 15, 1921, pp. 673–679, 9 figs. Details of plant of Trumbull-Cliffs Furnace Co. for delivery of hot metal to mixer at open-hearth building of Trumbull Steel Co.

Special Features of Blast Furnace Plant. Iron Age, vol. 108, no. 12, Sept. 22, 1921, pp. 730–732, 2 figs. Auxiliary features of new blast-furnace plant of Trumbull-Cliffs Furnace Co., Warren, Ohio, including methods of firing boilers, regulating blast and of handling water.

St. Louis. Blast-Furnace Plant of the St. Louis Coke and Chemical Company. Iron & Coal Trades Rev., vol. 103, no. 2791, Aug. 26, 1921, pp. 257–258, 6 figs. Describes general equipment. Includes two batteries of 40 coke ovens each.

Zinc. A Blast Furnace for Zinc, Evans W. Buskett. Eng. & Min. Jl., vol. 112, no. 11, Sept. 10, 1921, pp. 409–410. Experiments in smelting of ores under pressure suggested which might result in economies over present methods.

BOILER FEEDWATER

Grease in. Grease in Boiler Feed Water, Edward Ingham. Colliery Guardian, vol. 122, no. 3163, August 12, 1921, pp. 447–448. Explains how grease gets into boiler, its deleterious effect, and how to remove grease.

Softening. Boiler Feed Water Purification—II. Eng. & Indus. Management, vol. 6, no. 9, Sept. 1, 1921, pp. 230–231. Outlines respective merits of various methods used for boiler-feedwater treatment, with special reference to advantage of the Zeolite water-softening process.

Treatment. Boiler Feed Water Treatment and Treatment Control, E. G. Bashore. Combustion, vol. 5, no. 4, Oct. 1921, pp. 163–166. Discusses boiler compounds, feedwater heaters, continuous tank systems, intermittent tank system, zeolite, and internal treatment. (Abstract.) Paper read before Chem. Exposition.

Boiler Water Treatment Plants, Robert June. Blast Furnace & Steel Plant, vol. 9, no. 9, Sept. 1921, pp. 564–566. Formulates specifications for ideal water-purification plants.

The Treatment of Boiler Feed Water, Robert June. Power House, vol. 14, no. 17, Sept. 5, 1921, pp. 21–23, 2 figs. Discusses treatment with boiler compounds, graphite, kerosene, zinc, boiler metal treatment, water softening and purifying systems.

Water Treatment for Boilers, Julian S. Simsohn. Mech. Eng., vol. 43, no. 9, Sept. 1921, pp. 597–600 and 606, 2 figs. Various methods of water softening. Treatment of excessive concentration of soluble salts in boiler. Corrosion of boilers and economizers due to decomposition of organic compounds at high temperatures accompanying present steam pressures and superheats, etc.

BOILER OPERATION

Control. The Control of Boiler Operation, Walter N. Flanagan. Assn. Iron & Steel Elec. Engrs., vol. 3, no. 9, Sept. 1921, pp. 453–469, 5 figs. Discusses hand and automatic control, a.c. and d.c. drive for auxiliaries.

Efficiency as Affected by Draft. Boiler Efficiency

between efficiency, evaporative power and stokehold air pressure in steam boiler, in light of results of series of twelve exhaustive tests carried out by five authorities upon a marine boiler of Inglis type.

Efficient. Successful Boiler Operation, Guy L. Warden. Combustion, vol. 5, no. 3, Sept. 1921, pp. 116–117. Discusses type of equipment, its arrangement for operation, operators and their instructions, accessories and instruments.

Industrial. The Practical Operation of Industrial Boilers, W. E. Snyder. Mech. World, vol. 70, no. 1811, Sept. 16, 1921, pp. 231–232. Discusses instruments in boiler room and their proper use, training of operators, etc. (Continued.)

BOILER PLANTS

Equipment. Modern Boiler House Arrangement and Equipment, R. M. Gordon. Combustion, vol. 5, no. 4, Oct. 1921, pp. 159–161, 8 figs. Describes boiler plant of Solvay Process Co., an outgrowth of several smaller plants. (Abstract.) Paper read before Chem. Exposition.

BOILERS

Electrically Heated. Electrically Heated Steam Boilers, Eric A. Lof. Power Plant Eng., vol. 25, no. 18, Sept. 15, 1921, pp. 919–920, 3 figs. Electric boiler problem in general does not offer any technical difficulties; used where power is very cheap.

Hand-Fired. Hand-Fired-Boiler Performance in France, Carroll F. Merriam. Power, vol. 54, no. 13, Sept. 27, 1921, pp. 473–474. Contains abstract of report of First Subcommittee of Commission for Utilization of Fuels, published in Revue Générale de l'Électricité; and comparison of American and French boiler performances.

Steam-Heating. Largest Boiler to Supply Steam for Heating, J. H. Walker. Power, vol. 54, no. 13, Sept. 27, 1921, pp. 477–478, 2 figs. Details of saturated-steam boiler unit having 29,820 sq. ft. of steam-making surface, being installed in heating plant of Detroit Edison Co. Volume of combustion chamber, 11,440 cu. ft. Two 14-retort motor-driven underfeed stokers have fuel-burning capacity of 33,600 to 39,200 lb. of coal per hr.

BOILERS, WATER-TUBE

New Designs. The Three New Designs of Water Tube Boilers, Tsuruzo Matsumura. Jl. Soc. Mech. Engrs. & Soc. Nav. Architects, Sept. 1921. (In Japanese.)

BRAKES

Engine-Testing. Air-brakes for Engine Testing, Etc., A. T. Cross. Mech. Wld., vol. 70, no. 1808, August 26, 1921, pp. 168–169, 5 figs. Describes a cheap and simple method of constructing an absorption brake for determining the b.hp. of any size engine.

BRASS

Pickling of Strip. Continuous Pickling of Strip Brass, Wadsworth Doster. Metal Ind. (Lond.), vol. 19, no. 8, August 19, 1921, pp. 137–138, 4 figs. Describes the automatic strip cleaning machine used in brass rolling mills.

Red, Lead in. The Influence of Lead in Red Brass (Der Einfluss des Bleies im Rotguss), J. Czochralski. Zeit. fur Metallkunde, vol. 13, no. 7, Apr. 1921, pp. 171–178, 13 figs. Investigation of its influence on tensile strength, dilatation, hardness, torsional strength, and shock resistance.

Tempering with Tin Content. Tempering Brasses With a Tin Content (La Trempe des laitons à l'étain), Leon Guillet. Revue de Métallurgie, vol. 18, no. 7, July 1921, pp. 445–458, 26 figs. Concludes that one per cent of tin does not have the bad effect on mechanical properties generally attributed to it.

BRASS FOUNDING

Casting of Ingots. The Casting of Brass Ingots, R. Genders. Inst. Metals advance paper for meeting Sept. 21–22, 1921, no. 3, 4 pp., 2 figs.; also Engineering, vol. 112, no. 2908, Sept. 23, 1921, p. 452, 2 figs. Results of experiments carried out to minimize occurrence of non-metallic inclusions. Describes method involving use of short broad tapered ingots with dozzle feed, by use of which, it is claimed, failures and wastage were considerably reduced.

England. Modern Developments in the British Brass Industry, Ernest A. Smith. Am. Electrochemical Soc. advance paper, no. 24, for Meeting, Sept. 29–Oct. 1, 1921, pp. 301–326. Discusses electric brass furnaces in England; extrusion, hot pressing and forging of brass; rolling-mill practice; annealing; composition of industrial brasses; and treatment and utilization of scrap brass.

BRONZES

Low-Tin. The Effect of Progressive Cold-Drawing upon Some of the Physical Properties of Low-Tin Bronze, W. E. Alkins and W. Cartwright. Inst. Metals advance paper for meeting Sept. 21–22, 1921, no. 6, 23 pp., 17 figs. Experimental data is summarized in diagrams showing variation during cold-drawing of the three properties, tensile strength, specific volume, and scleroscope hardness.

Manganese. Casting Manganese Bronze Test Bars, E. H. Dix, Jr. Foundry, vol. 49, no. 18, Sept. 15, 1921, pp. 734–736, 1 fig. Discusses several methods of casting and compares results of physical tests.

C

CAR WHEELS

Molding. Molds Car Wheels on Jolt Machines. Systems for transferring molds, flasks and sand.

Novel Mechanical Molding of Car Wheels. Iron Age, vol. 108, no. 11, Sept. 15, 1921, pp. 662–664, 6 figs. Foundry of Brown Car Wheel Works, Inc., Buffalo, N. Y., has moving platform to handle molds from molding machines, through pouring stage and to shake-out machines.

Tires. British Standard Specification for Tramway Tyres. British Eng. Standards Assn., no. 101, July 1921, 11 pp., 7 figs. Includes conversion table from tons to pounds; appendix giving forms of British standard tensile test pieces; and diagram illustrating British standard tires for tramway driving and pony wheels.

CARBURETORS

Zenith Triple-Diffuser. A New Carburetor (Un Nouveau Carburateur), R. Villers. La Nature, no. 2471, August 13, 1921, pp. 100–104, 7 figs. Describes Zenith triple-diffuser carburetor.

CARS

Frames. A Study of Carriage Frames (Etude des Chassis de Wagons), M. Le Touzé. Revue Générale des Chemins de Fer, vol. 40, no. 9, Sept. 1921, pp. 185–205, 11 figs. Calculates stresses in car or carriage frames when over 10–12 in. long and describes successful method of construction by Compagnie de l'Est.

CARS, PASSENGER

Insulation-of. Insulation of Passenger and Refrigerator Cars, Arthur J. Wood. Ry. Mech. Engr., vol. 95, no. 9, Sept. 1921, pp. 547–549. Discussion of principles involved in determining heat transmission under various conditions.

CARS, REFRIGERATOR

Temperature Control. Controlling Refrigerator Car Temperature in Winter Months. Ry. Rev., vol. 69, no. 10, Sept. 3, 1921, pp. 293–297, 9 figs. Department of Agriculture makes practical suggestions for reducing loss and damage to fruit shipped in refrigerator cars during winter months.

CASTINGS

Breaking and Deformation. Breaking and Deformation of Castings Whose Thickness Varies Very Much (Rotture e Deformazione Nei Getti di Ghisa a Spessori Assai Diversi), Piero Gatti. L'Industria, vol. 35, no. 14, July 31, 1921, pp. 319–321, 2 figs. Discusses design, patterns, quality of metal, drill molds.

Specification and Testing. The Specification and Testing of Castings, Walter Rosenhain. Automotive Industries, vol. 45, no. 5, August 4, 1921, pp. 217–219. Analyzes various methods and indicates best practice under present conditions.

CENTRAL STATIONS

Power in Middle West. Location and Distribution of the Central-Station Power of the Middle West, W. L. Abbott. Mech. Eng., vol. 43, no. 7, July 1921, pp. 443–444 and 458, 2 figs. Notes on location of water powers; question of power plants at mine mouth; location of power stations and distribution lines.

CHAIN DRIVE

Roller Chain. The Development of the Roller Chain Drive, G. M. Bartlett. Automotive Industries, vol. 45, no 8, August 25, 1921, pp. 363–366, 6 figs. Discusses changes in design and construction of chains and sprockets and a new form of roller-chain sprocket tooth. From paper presented at meeting of Gear Manufacturers' Assn.

CHROME-NICKEL STEEL

Heat Treatment and Characteristics. Nickel-chromium Steels: Their Heat-Treatment and Characteristics, W. E. Murphy. Machinery (Lond.), vol. 18, no. 465, August 25, 1921, pp. 638–639, 2 figs. Gives mechanical properties; shows effect after oil-hardening and air-hardening.

CHUCKS

Magnetic. Magnetic Chucks Require Careful Mounting, F. Horner. Can. Machy., vol. 26, no. 9, Sept. 1, 1921, pp. 33–35, 7 figs. Mounting can be of permanent or temporary character; magnetic holding faces of chuck must be absolutely correct.

COAL HANDLING

Locomotive Cranes. Economical Coal Handling With Locomotive Cranes, H. D. Fisher. Combustion, vol. 5, no. 3, Sept. 1921, pp. 108–110, 4 figs.

Power Installation. Power Installation at Coverdale Mine, Charles M. Means. Trans. Am. Inst. Min. & Metallurgical Engrs., no. 1101-C, Sept. 1921, 14 pp., 3 figs. Details of coal-handling system installed at Pittsburgh Terminal R. R. & Coal Co.'s new shaft. Main hoist is first Ilgner-Ward-Leonard hoisting installation in Pittsburgh district. Operating conditions: Total lift, 405 ft.; inclination of shaft to horizontal, 90 deg.; weight of cage, 20,000 lb.; weight of load (coal) 10,000 lb., (slate) 16,000 lb.; weight of cars, 5000 lb.

COLD STORAGE

English Docks. The Development of Cold Storage at the Avonmouth Docks, Thomas A. Peace. Cold Storage & Ice Assn. Proc., vol. 17, no. 2, 1921, pp. 17–32 and (discussion) 33–40, 3 figs. on supp. plates. Describes cold storage in various transit sheds, refrigerating machinery in Avonmouth and Royal Edward docks, and electrical arrangements.

Mechanical Handling of Meats and Produce. The Mechanical Handling of Meat and Produce in Cold Storage, S. G. Calladine. Cold Storage & Ice Assn. Proc., vol. 17, no. 2, 1921, pp. 43–50 conveyors used, comparative cost, etc.

Piping for Rooms. Piping Required in Cold Storage Rooms, Benj. J. Masters. Southern Engr., vol. 36, no. 1, Sept. 1921, pp. 38–41. Calculates piping for various conditions.

COMBUSTION

New Theories. New Combustion Theories (Nyare Förbränningsteorier), Hilding Håkanson Teknisk Tidskrift (Veckoupplagan), vol. 51, no. 37, Sept. 17, 1921, pp. 381–387, 6 figs. Discusses theories of Nusselt, Neumann, Aufhäuser.

CONDENSERS, STEAM

Air Pumps for. Recent Improvements in Condensing Apparatus for Steam Engines (Recents perfectionnements des appareils de condensation des machines a vapeur d'eau), L. Jauch. Chaleur et Industrie, vol. 2, no. 16, August 1921, pp. 501–508, 13 figs. Discusses air pumps of various types. (Continuation of serial.)

Scale Prevention. Installations for the Prevention of Scale Formation in Surface Condensers (Anlagen zur Verhütung von Wassersteinbildung in Oberflächen-Kondensationen), Hans Rissmann. Zeit. des Oberschlesischen Berg- u Hüttenmännischen Vereins, vol. 59, no. 6, 1920, pp. 185–205, 33 figs. The Balcke inoculation process as modern protection against incrustation and silting up with mud, and its economic advantages. Process so-called because it renders cooling water immune from influence of scale-producing salts.

Surface. Surface Condenser Operation, George C. Cook. Power, vol. 54, no. 10, Sept. 6, 1921, pp. 365–367. Notes on vacuum decrease with temperature increase; quantity of circulating water required; air and steam distribution; removing deposits from inside surfaces; and other methods of cleaning.

Surface and Jet. Modern Surface and Jet Condensers, K. Hoefer. Eng. Progress, vol. 1, no. 7–8, July-August 1920, pp. 237–242, 14 figs. Describes various types, results of tests, cleaning during running.

Tests of Various Types. Relative Efficiency of Various Types of Condensing Apparatus, Allen F. Brewer and Frank A. Stivers. Mech. Eng., vol. 43, no. 10, Oct. 1921, pp. 672–673. Results of comparative tests carried out on double-pipe coils, submerged coils with and without manifolds, and cooling towers, and of value as guide in selection and design of most efficient type of condenser.

Water-Distributing Device. New Water Distributing Device For Condensers, George M. Kleucker. Ice & Refrigeration, vol. 61, no. 2, August 1921, p. 84, 1 fig. Discusses U. S. Patent 1,291,926.

CONNECTING RODS

Machining. Machining Connecting Rods. Machinery (Lond.), vol. 18, no. 369, Sept. 22, 1921, pp. 759–763, 13 figs. Manufacturing methods employed by Austin Motor Co., Longbridge Works, Birmingham, for producing balanced connecting rods.

COPPER ALLOYS

Copper-Zinc. The Density of the Copper-Zinc Alloys, T. C. Bamford. Inst. Metals advance paper for meeting Sept. 21–22, 1921, no. 4, 12 pp., 4 figs. Results of investigation of both chill and sand-cast billets show that with only one exception the densities of sand-cast specimens are less than those of chill-cast ones.

COST ACCOUNTING

Mechanical. Cost Accounting by Machinery, E. W. Workman. Eng. & Indus. Management, vol. 6, no. 12, Sept. 22, 1921, pp. 314–318, 4 figs. Describes Hollerith systems of mechanical sorting and tabulating, application of these systems to problems of collecting labor and overhead expenses, and applying them to costs of manufactured articles, etc.

Methods. The Necessity of Proper Cost Accounting, J. B. Sehl. Forging & Heat Treating, vol. 7, no. 8, August 1921, pp. 432–434. Methods of distributing expense over product are, the percentage, man hour, sold hour, list percentage and machine rate for production center methods.

Overhead, Allocation of. The Correct Allocation of On-Costs, H. Varley. Eng. & Indus. Management, vol. 6, no. 9, Sept. 1, 1921, pp. 241–242. Where reductions can be made.

Uniform System. Uniform Cost System Use Advised, Robert E. Belt. Iron Trade Rev., vol. 69, no. 13, Sept. 29, 1921, pp. 807–809. Points out benefits to be derived by introduction of such a system; too much detail has proved detrimental. States that accountant should be familiar with manufacturing methods.

CRANES

Harbor. Modern Harbour Cranes, Richard Hänchen. Eng. Progress, vol. 1, no. 6, June 1920, pp. 203–210, 10 figs. Describes slewing, travelling, gantry, and double cranes.

Level Luffing. A Level Luffing Crane. Engineer, vol. 132, no. 3431, Sept. 30, 1921, p. 354, 2 figs. Outstanding feature of crane supplied to Great Western Ry. Co. by Wellman Smith Owen Eng. Corp., Ltd., London, is arrangement provided for moving load along a horizontal path while jib of crane is being luffed, thus saving both time and power in manipulating it.

Operator's Manual. Crane Operator's Manual, L. F. Galbraith. Assn. Iron & Steel Elec. Engrs., vol. 3, no. 9, Sept. 1921, pp. 437–452, 12 figs. Duties

of crane operators, including inspection, reports, operations, etc. (Report of Educational Committee for 1921.)

Shipyard. Mammoth Cranes For Shipyard and Harbour Service, Richard Hänchen. Eng. Progress, vol. 1, no. 11, November 1920, pp. 335–339, 11 figs. Describes stationary cranes, their construction and development, including cantilever jib cranes of 250 tons carrying capacity.

Steam Goliath. 20-Ton Steam Goliath Crane. Engineer, vol. 132, no. 3432, Oct. 7, 1921, p. 381, 2 figs. on p. 374. Built for 60-ft. span with clear lift of 32 ft. Engines are of double-cylinder and boiler of vertical type.

CUTTING TOOLS

Selection and Use. Selection and Proper Use of Cutting Tools. Can. Machy., vol. 26, no. 9, Sept. 1, 1921, pp. 36–40, 15 figs. Discusses design, use in operation, maintenance, etc.

CYLINDERS

Steel, Tests of. Experiments on the Effects of Extremely High Pressures, P. W. Bridgman. Compressed Air Mag., vol. 26, no. 9, Sept. 1921, pp. 10223–10225, 4 figs. Describes experimental tests of tool steel and mild steel cylinders, the former rupturing at 40,000 atmospheres.

D

DIE CASTING

Advantages. Die Casting—I and II, A. G. Hopking. Engineer, vol. 132, nos. 3429 and 3430, Sept. 16 and 23, 1921, pp. 281–282 and 309–311, 5 figs. Description and advantages of die-casting process, and some of its uses.

DIES

Die-Sinking Machines. Die Sinking and Metal Patternmaking by Automatic Machine, Joseph F. Keller. Mech. Eng., vol. 43, no. 9, Sept. 1921, pp. 584–588 and 606, 16 figs. Discusses dies used for stamping, forging, embossing, pressing, etc. Notes on various methods employed in die sinking; automatic die-sinking machines; duplicating machines; advantages and relative cost of machine-cut dies.

Die-Sinking Machine. Engineering, vol. 112, no. 2905, Sept. 2, 1921, pp. 341–342, 4 figs. Constructed by Bryant Symons & Co., London, for cutting dies used in drop-forging work.

Electrical Terminals and Connectors. Dies for Electrical Terminals and Connectors. Machinery (Lond.), vol. 18, no. 468, Sept. 15, 1921, pp. 733–736, 10 figs. Discusses piercing, trimming and forming dies, and dies for making band clamp ends.

Self-Opening Die Heads. Self-Opening Die Heads. Eng. Production, vol. 3, nos. 51 and 52, Sept. 22 and 29, 1921, pp. 269–274 and 296–300, 35 figs. Design, construction and application.

DIESEL ENGINES

Construction and Lubrication. Diesel Engine Practice—I, A. H. Pritchard. Power Plant Eng., vol. 25, no. 18, Sept. 15, 1921, pp. 901–903, 4 figs. Discusses Diesel oil engine, construction and lubrication.

Ignition. Internal-Combustion Engines, Charles E. Lucke. Power, vol. 54, no. 13, Sept. 27, 1921, pp. 479–483, 18 figs. Ignition problems in semi-Diesel and Diesel oil engines.

Improvements. Innovations in Diesel Engine Construction. Mar. Eng., vol. 26, no. 9, Sept. 1921, pp. 700–701, 1 fig. German builders introducing novelties in Burmeister and Wain design; Blohm and Voss building new double acting engine.

Knocks. Knocks in Diesel Engines, Louis R. Ford. Power, vol. 54, no. 9, Aug. 30, 1921, pp. 327–328. Deals with worn bearing knocks, knocks in valve gear, and within cylinder. Characteristics and causes.

Marine. Diesel and Semi-Diesel Marine Engines—Renault System (Les moteurs Diesel et Semi-Diesel Marine—système Renault), Ch. Dantin. Le Génie Civil, vol. 79, no. 11, Sept. 10, 1921, pp. 221–225, 10 figs. Discusses large increase in heavy-oil engines; describes Renault 300-hp. Diesel and 80-hp. semi-Diesel.

Marine Diesel Engine Operation (La conduite des moteurs Diesel marins), Y. Le Gallou. Bulletin Technique du Bureau Veritas, vol. 3, no. 7, July 1921, pp. 160–163. Studies causes of bad functioning, including air compressors and their influence, lubricating, etc. (Concluded.)

Overhauling. Overhauling an Oil Engine, G. Grow. Power, vol. 54, no. 10, Sept. 6, 1921, pp. 375–377, 7 figs. Author's experience in overhauling a Diesel engine.

DROP FORGING

Design of Parts. The Art of Drop Forging with Examples of Work. Can. Machy., vol. 26, no. 12, Sept. 22, 1921, pp. 25–28, 4 figs. Discusses design of parts, additional strength due to drop forging, etc.

Dies. Design and Making of Drop-forging Dies. Machy. (N. Y.), vol. 28, no. 2, Oct. 1921, pp. 123–124. Methods of heating, quenching and drawing carbon and alloy-steel dies.

Design and Making of Drop-forging Dies. Machinery (Lond.), vol. 18, no. 469, Sept. 22, 1921, pp. 749–752, 7 figs. Methods employed in modern drop-forging plants; die-sinking machines, two-impression dies, trimming, etc.

Drop Forgings—I. Machinery (Lond.), vol. 18, no. 468, Sept. 15, 1921, pp. 738–739, 3 figs. Discusses quantity required, quality of steel in drop forgings, simplicity or otherwise of dies required, and die cutting or sinking.

DRYING

Methods and Machines. Drying (Das Trocknen), H. Hausbrand. Zeit. des Vereines deutscher Ingenieure, vol. 65, nos. 33, 37 and 38, Aug. 13, Sept. 10 and 17, 1921, pp. 863–868, 966–970 and 994–998, 85 figs. Discusses various different properties of materials affecting their behavior during process of drying. Deals with drying through direct contact with heating surfaces, and with air drying. Schematic presentation of number of devices and machines used in drying.

E

EDUCATION

General, Needs of. General Education and the Engineering Profession, H. E. Miles. Mech. Eng., vol. 43, no. 8, Aug. 1921, pp. 517–520 and 550, 7 figs. Points out lack of vocational schools in United States and need for longer school year. Notes on continuation schools and training of teachers.

EDUCATION, INDUSTRIAL

Training of Metal Workers. The National Metal Trades Association and Industrial Education, Harold C. Smith. Mech. Eng., vol. 43, no. 8, Aug. 1921, pp. 521–522 and 550. Outline of its activities in training of new workers, with opinions of its committee on industrial education regarding apprenticeship, trade and continuation schools, instruction of foremen, training in plant, and vestibule schools.

ELECTRIC DRIVE

Mechanical Difficulties. Reducing Mechanical Difficulties With Motor-Driven Applications, Raoul Pruger and Louis A. Deesz. Elec. Jl., vol. 18, no. 9, Sept. 1921, pp. 408–413, 9 figs. Considers belted, geared, chain-driven and direct-connected drives, cushioned and uncushioned loads, etc.

ELECTRIC FURNACES

Annealing. Design Electric Annealing Furnace, C. E. Chaney. Foundry, vol. 49, no. 18, Sept. 15, 1921, pp. 720–723, 6 figs. Malleable iron is annealed in 42 hours.

Fuel-Fired vs. Comparison of Electric Furnace Practice with Fuel-Fired Furnace Practice, N. K. B. Patch. Am. Electrochemical Soc. advance paper, no. 22, for Meeting, Sept. 29–Oct. 1, 1921, pp. 287–290. Author's experiences are that cost of metal melted, melting losses, and solution of gases in metal, are substantially the same in electric and fuel-fired furnace, provided intelligent operation is pursued.

Girod. Electric Furnaces for Making Steel—VI, Alfred Stansfield. Blast Furnace & Steel Plant, vol. 9, no. 9, Sept. 1921, pp. 550–552, 1 fig. Describes Girod electrode-hearth arc-furnace at Bethlehem Steel Co.

Gray-Iron. Electric Furnace Gray Iron, Jas. L. Cawthon, Jr. Elec. Jl., vol. 18, no. 9, Sept. 1921, pp. 396–400, 4 figs. Discusses economies compared with cupola, addition of silicon, temperature control, etc.

Heat-Treating. Electric Furnaces and Heat Treatment, Edwin F. Cone. Iron Age, vol. 108, no. 11, Sept. 15, 1921, pp. 643–648, 10 figs. Survey of their commercial application to steel and other industries.

Levoz. The Electric Furnace (Le four électrique). Révue d'Electrochimie & d'Electrometallurgie, vol. 15, no. 3–4, March–April, 1921, pp. 57–61. Describes Levoz furnace which is capable of producing a good quality of metal with a minimum expenditure of electric power.

Muffled-Arc-Type. Recent Developments in Electric Furnaces of the Muffled Arc Type, H. A. Winne. Am. Electrochemical Soc., advance paper, no. 19, for Meeting, Sept. 29–Oct. 1, 1921, pp. 263–272, 5 figs. Smaller units of 1500 lb. and 100 lb. per hr. capacity are described in comparison to larger rectangular shell-type furnace. Discusses advantages of muffled-arc furnaces.

Non-Ferrous Metals. The Influence of the Electric Furnace on the Metallurgy of Non-Ferrous Metals, H. M. St. John. Am. Electrochemical Soc., advance copy, no. 3, pp. 55–75. Discusses gradual breaking down of secretiveness as to methods and results, melting of high-quality brass and bronze in ton lots, more convenient and economical handling of charges, etc. (Abstract.)

Progress in 1921. Electric Furnace Progress in 1921, E. T. Moore. Iron Age, vol. 108, no. 12, Sept. 22, 1921, pp. 723–724. Discusses merits of dual voltages for melting steel and for refining. Heat losses and electrodes are considered. Report submitted to Assn. Iron & Steel Elec. Engrs.

Resistance-Type. Electric Resistance Furnaces, E. P. Barfield. Elec. Rev. (Lond.), vol. 89, no. 2286, Sept. 16, 1921, p. 364. Discusses heat treatment of steel by electricity and other applications, power cost, etc.

Resistance Type Electric Furnace in the Melting of Brass and Other Non-Ferrous Metals, T. F. Baily. Am. Electrochemical Soc., advance paper, no. 20, for Meeting, Sept. 29–Oct. 1, 1921, pp. 273–279. Discusses various features to be considered, and summarizes advantages and disadvantages of resistance-type as compared with other types.

Rotary. Rotary Electric Furnace Shows Marked Advantages, Alan D. Dauch. Elec. Wld., vol. 78, no. 12, Sept. 17, 1921, pp. 565–566, 2 figs. This furnace replaces oil-fired furnaces for continuous heat treating, annealing and carbonizing.

Superheats in. Superheats in the Electric Furnace, George K. Elliott. Foundry, vol. 49, no. 18, Sept. 15, 1921, pp. 714–719. Discusses temperature losses, temperature limit for cupola iron, deoxidation, limits of sulphur, etc.

Types. Electric Furnaces, Ezer Griffiths. Beama, vol. 9, nos. 2 and 3, Aug. and Sept. 1921, pp. 145–150, 5 figs., and 254–259, 4 figs. Describes carbon-resistor furnace, vacuum furnace, furnaces for testing refractories and for experiments under high gaseous pressures; arc, induction high-frequency induction and vacuum cathode ray furnaces.

ELECTRIC LOCOMOTIVES

Operating Characteristics. Operating Characteristics of the Electric Locomotive, N. W. Storer. Ry. Rev., vol 69, no. 6, August 6, 1921, pp. 169–173, 5 figs. Discusses changes due to general adoption of electrification and adaptability of electric locomotives.

Swiss. Electric Locomotives of the Bernese Railway (Locomotives électriques des chemins de fer Bernois), Lucien A. -H. Pahin. L'Industrie Electrique, vol. 30, no. 701, Sept. 10, 1921, pp. 328–331. Data on 2–4+4–2 locomotives of 8000 kg. tractive effort, also mechanical and electrical equipment.

Electric Traction in Switzerland. Electrician, vol. 87, no. 2261, Sept. 16, 1921, pp. 348–352, 7 figs. Discusses freight-locomotive details, express locomotives 1-C-1 and 1-B+B-1, freight locomotive 1-C+C-1, and their electrical equipment. (Concluded.)

Vibration of. Diagram of the Vibrations of an Electric Locomotive with Coupling Rods (Diagramm der Schuttelschwingungen einer elektrischen Lokomotive mit Stangenantrieb), A. Wichert. Elektrotechnische Zeit., vol. 42, no. 17, Apr. 28, 1921, pp. 427–430, 2 figs. Torsion diagrams are presented which were taken on an electric locomotive with a single motor after it had been at work 18 months, and which, in author's belief, tend to confirm theories already advanced by him. Various vibrations, as shown on torsion diagram, are examined with view to tracing connection between their periodicity and other variables of problem.

Modern Theories on the Vibration Phenomena of Electric Locomotives with Parallel-Crank Drives (Neuere Theorien der Schüttelerscheinungen elektrischer Lokomotiven mit Paralellkurbelgetrieben), A. Wichert. Elektrotechnische Zeit., vol. 42, nos. 5, 6 and 7, Feb. 3, 10 and 17, 1921, pp. 103–107, 128–132 and 151–154, 19 figs. Gives mechanical analysis and criticism of observations and data made by seven different European authors on complex problems of vibrations of rod-driven electric locomotives. Viewpoints of different writers in their attempt to analyze and remedy dangerous vibrations on such drives.

ELECTRIC WELDING

Oil Tanks. Electric Welding of Oil Storage Tanks, William Schenstrom. Welding Engr., vol. 6, no. 9, Sept. 1921, pp. 49–52, 7 figs. Discusses advantages of welded over riveted, and need for standardized methods. Paper read before Am. Welding Soc.

ELECTRIC WELDING, ARC

Electrodes. Electric Arc Welding With Metal Electrode (Lysbuesvejsning med Metalelektroder), J. Clausen. Teknisk Tidsskrift (Elektroteknisk), vol. 17, no. 32, August 10, 1921, pp. 117–122, 4 figs. Reviews development of this method and discusses quality of electrodes, power required and efficiency of weld. (To be continued.)

ELECTRON METAL

See MAGNESIUM ALLOYS, Electron Metal.

ELEVATORS

Electric. Electric Elevator Machinery—Elevator Cables, Their Care and Inspection, M. A. Myers. Power, vol. 54, no. 10, Sept. 6, 1921, pp. 369–371, 7 figs. Types of elevator rope, machines and accessories. Cable measurement.

Motor-Control Equipment. Motor-Control Equipment Used in Elevator Service—I, G. J. Kirkgasser and E. W. Seeger. Elec. Rev. (Chicago), vol. 79, no. 13, Sept. 24, 1921, pp. 465–468, 8 figs. Machines, roping, brakes and motors employed in operation of elevators; features of magnetic and mechanical controllers; diagrams and illustrations of circuits and control devices. (To be continued.)

EMPLOYMENT MANAGEMENT

Employment System. A Modern Factory Employment System, W. H. Rohr. Wood-Worker, vol. 40, no. 7, Sept. 1921, pp. 27–29, 8 figs. Discusses the question of reducing labor turnover.

Hiring System. Efficient System of Hiring Men, Russel J. Waldo. Machy. (N. Y.), vol. 28, no. 2, Oct. 1921, pp. 135–137, 7 figs. Methods adopted by large manufacturing plant for insuring selection of applicants best suited for work.

ENGINEERS

Education and. Making Better Engineers of College Men. Elec. Wld., vol. 78, no. 12, Sept. 17, 1921, pp. 567–569. Power to think is more important than mind filled with facts.

The Character of the Engineer. Times Eng. Supp., no. 563, Sept. 1921, p. 259. Discusses natural qualifications and education as training. Believes there is room for all really fit.

ETHYLENE

Preparation from Acetylene. The Preparation of Ethylene by Hydrogenation of Acetylene, William H Ross, James B. Culbertson and J. P. Parsons. Jl. Industrial & Eng. Chem., vol. 13, no. 9, Sept. 1921, pp. 775–778, 3 figs. Discusses preparation

EVAPORATORS

Design. Studies in Evaporator Design—V, W. L. Badger. Chem. & Met. Eng., vol. 25, no. 10, Sept. 7, 1921, pp. 459–463, 5 figs. Experimental data for horizontal-tube evaporator showing relation between hydrostatic head, temperature drop and heat transmission.

EXTRUSION OF METALS

Extrusion Defect. The Extrusion Defect, R. Genders. Inst. Metals advance paper for meeting Sept. 21–22, 1921, no. 7, 9 pp., 12 figs.; also Engineering, vol. 112, no. 2909, Sept. 30, 1921, pp. 487–489, 12 figs. Describes method which is said to be successful in avoiding formation of extrusion defect, and is in use in many places for production of tubes and rod from soft metals such as lead and aluminum. Writer suggests its use for extrusion of copper alloys.

F

FACTORIES

Hygienic Arrangements. Modern Industrial-Hygienic Arrangements for Factories (Zeitgemässe gewerbehygienische Einrichtungen für Fabrikbauten), Otto Brandt. Betrieb, vol. 3, no. 23, Aug. 27, 1921, pp. 728–738, 22 figs. Points to necessity of maintaining pure air in work rooms. Most dangerous kinds of dust found in industrial works are visualized with aid of photomicrographs, and installations for removal of dust, smoke, gases, vapors, and arrangements for supplying moisture to air are described. In connection with dust-removal plants, installations for recovery of valuable kinds of dust from dust-laden air and metallurgical gases are discussed.

Layout. Production Plans and Layout of Factories (Fabrikbauten und Umstellungen), Otto Hardung. Betrieb, vol. 3, no. 23, Aug. 27, 1921, pp. 751–759, 6 figs. Determination of working periods, dimensions, required machines and materials, based on complete production plant in a new system and separate working systems. Discusses desiderata for selection of factory site and layout.

Maintenance. Factory and Plant Maintenance—II, Arnold A. Arnold. Mech. World, vol. 70, no. 1811, Sept. 16, 1921, pp. 222–223. Discusses various works plans that it may be advisable to keep and information they record, also inventory of machinery and plant. (To be continued.)

FLAME PROPAGATION

Definition. Flame, C. A. French. Jl. Soc. Automotive Engrs., vol. 9, no. 3, Sept. 1921, pp. 182–185 and (discussion) 185–188, 1 fig. Discusses definition of atomic theory, combustion, oxidation and flame propagation.

FLIGHT

Circling. Control in Circling Flight, F. H. Norton and E. T. Allen. Natl. Advisory Committee For Aeronautics, Report no. 112, 22 pp., 52 figs. Results of investigation for the purpose of developing instruments that would record forces and positions of all three controls and to obtain data on behavior of an airplane in turns.

FORGINGS

Ordnance, Heat Treatment of. Observations Made in the Heat Treatment of Ordnance Forgings, Paul E. McKinney. Trans. Am. Soc. for Steel Treating, vol. 1, no. 12, Sept. 1921, pp. 738–745, 3 figs. Shows the necessity of having most complete data on material handled for successful heat treatment and to avoid erroneous deductions.

Press. A Method of Designing Press Forgings, W. R. Ward. Forging & Heat Treating, vol. 7, no. 8, August 1921, pp. 428–430. Combination of practical and theoretical gives best results working from finished forging back to billet.

FOUNDRIES

Core Rooms. Improved Core Output from Smaller Space. Iron Age, vol. 108, no. 15, Oct. 13, 1921, pp. 927–929, 4 figs. By providing improved working conditions for girl core makers, better product and higher type of employee have been secured.

Electric Suspension Travelers. Electric Suspension Traveller in Foundries, Richard Hänchen. Eng. Progress, vol. 1, no. 5, May 1920, pp. 181–185, 10 figs. Describes types made by various manufacturers.

Ford Motor Co. New Ford Foundry Plant at River Rouge, L. B. Breedlove. Iron Age, vol. 108, no. 13, Sept. 29, 1921, pp. 787–793, 7 figs. Laid out for quantity production. Uses direct blast-furnace metal mixed with cupola metal in definite proportions as required. Conveyor systems highly developed.

Malleable Iron. Equipment Features Malleable Shop, H. E. Diller. Iron Trade Rev., vol. 69, no. 15, Oct. 13, 1921, pp. 935–942 and 950, 14 figs. Details of new foundry of American Chain Co., New York, located at York, Pa., showing radical departures from general practice in all three stages of conveying, melting and annealing.

Manufacturing System. Manufacturing System Applied to the Foundry. Machinery (Lond.), vol. 18, no. 466, Sept. 1, 1921, pp. 664–671, 20 figs. Review of system developed by Derwent Foundry Co. (1920), Ltd., Derby.

Mixtures. Figuring the Charges for Foundry Irons, Y. A. Dyer. Iron Age, vol. 108, no. 15, Oct. 13, 1921, pp. 931–933. Iron mixtures and how to figure them chemically. Classification of castings and suggested analyses.

additions to equipment to modernize plant.

Steel Foundry Makes Sugar Mill Machinery—I, James J. Zimmerman. Blast Furnace & Steel Plant, vol. 9, no. 9, Sept. 1921, pp. 536–540, 3 figs. Discusses milling or rolling equipment and its proper selection.

FREIGHT HANDLING

Automatic Unloading Devices. The Economy of Modern Automatic Unloading Devices in Railroad Transportation (Ueber die Wirtschaftlichkeit moderner Selbstentladevorrichtungen im Eisenbahntransportwesen), Hartwig Orenstein. Fördertechnik u. Frachtverkehr, vol. 14, nos. 15, 16, 17 and 18, July 22, Aug. 5, 19 and Sept. 2, 1921, pp. 171–174, 186–189, 205–208 and 221–224, 27 figs. Technical part: Development of types of automatic unloaders and wagon-tipping devices; operating conditions; loading and unloading plants. Economical part: Calculation of an example; costs and their variability; formula is developed and its application under different conditions explained.

Slow Traffic. On the Question of Slow-Freight Traffic, W. H. Williams. Bul. International Ry. Assn., vol. 3, no. 8, August 1921, pp. 1087–1101, 2 figs. Discusses loading and unloading, yard and train operation, freight car movement, freight rates, etc.

FUELS

Coke Breeze as Boiler Fuel. Value of Mixture of Coke Breeze and Bituminous Coal as Fuel for a Hand-Fired Boiler, John Blizard and James Neil. Jl. Am. Soc. Heating & Ventilating Engrs., vol. 27, no. 6, Sept. 1921, pp. 645–655, 2 figs. Tests carried out by Bur. of Mines show that mixtures of coarser coke breeze with Pittsburgh coal gave less than one-half the smoke given out by Pittsburgh coal alone, about 20 per cent less steam, and require stronger draft to burn them; steaming value is about 70 per cent that of Pittsburgh run-of-mine coal, and its price should be less than 70 per cent that of Pittsburgh coal. Finer coke breeze can be recommended only for use at low rates of combustion.

Influence on Engine Performance. The Influence of Various Fuels on Engine Performance—V, H. R. Ricardo. Automotive Industries, vol. 45, no. 5, August 4, 1921, pp. 211–216, 11 figs. Relation between mixture strength and indicated mean pressure for various fuels, compression ratios and spark timing is shown and influence of jacket water temperature and heating of charge determined. From preliminary report conducted for Asiatic Petroleum Co.

Mixed Culm and Pitch. Mix Culm and Pitch in New Fuel, Donald Markle. Iron Trade Rev., vol. 69, no. 12, Sept. 22, 1921, pp. 753–755. New heating material prepared by mixing anthracite coal and pitch; designed for use in blast furnace and metallurgical operations and for domestic heating. By-products are limited. (Abstract.) Paper presented before Am. Inst. Min. & Metallurgical Engrs.

Smokeless. The Present Position of Smokeless Fuels, F. S. Sinnatt. Iron & Coal Trades Rev. vol. 103, no. 2790, August 19, 1921, p. 233. Concludes that manufacture of some type of smokeless fuel would solve the problems of fuel conservation, air pollution and efficient house heating; coal should be worked at pithead or in conjunction with coal gas. (Abstract.) Paper read before Royal Sanitary Inst.

[See also OIL FUEL; PULVERIZED COAL.]

FURNACES

Preheated-Air vs. Direct-Fired. Experimental Comparison of a Preheated Air Furnace With a Direct Fired Furnace, L. Lellep. Am. Gas Jl., vol. 115, no. 12, Sept. 17, 1921, pp. 247–252 and 260–263, 4 figs. Discusses results of experiments and gives table of theoretical computation of fuel saving due to preheated air compared with fuel consumption in a direct-fired furnace.

FURNACES, BOILER

Improvements. The Reconstruction of Steam-Boiler Furnaces and Their Auxiliary Equipment for Obtaining a Maximum Conservation of Fuel (Die Umstellung der Dampfkesselfeuerung und ihrer Nebeneinrichtungen zur Erzielung grösster Brennstoff-Ökonomie), H. Briem. Fördertechnik u. Frachtverkehr, vol. 14, no. 14, July 8, 1921, pp. 156–161, 9 figs. Deals with ash-removal installations; forced-draft furnaces; and electric boiler protection.

Recovery of Unburned Fuel from Refuse. The Recovery of Unburned Fuel from Boiler Furnace Refuse, Thomas Fraser and H. F. Yancey. U. S. Bur. Mines Reports of Investigations serial no. 2281, Sept. 1921, 3 pp. Washing tests made in laboratory of mining department of University of Illinois show possibility of recovering unburned fuel by crushing refuse to ¾-in. ring size, washing on coal-washing tables, and removing slime from washed product by a dewatering conveyor-elevator or screen.

FURNACES, HEATING

Regenerative. Employ Regenerative Furnaces, E. C. Kreutzberg. Iron Trade Rev., vol. 69, no. 11, Sept. 15, 1921, pp. 680–683, 7 figs. Installation at Harrison, N. J., comprises 24 units, to burn either oil or gas. Operation is explained and results of tests are given.

FURNACES, HEAT-TREATING

Automatic Semi-Cylindrical. New Heat-Treating Furnace. Iron Age, vol. 108, no. 11, Sept. 15, 1921, p. 665, 1 fig. Automatic furnace, known as A. D. Dauch. Iron Age, vol. 108, no. 11, Sept. 15, 1921, pp. 666–667, 4 figs. Moving hearth is an annular ring; heated electrically and controlled automatically; suitable for large variety of parts. Installed at plant of Nash Motors Co., Kenosha, Wis.

FURNACES, HOT-AIR

Small Blowers for. Small Blowers in Combination with Furnaces for Domestic Heating Plants, F. R. Still. Jl. Am. Soc. Heating & Ventilating Engrs., vol. 27, no. 6, Sept. 1921, pp. 659–663, 2 figs. Describes type of air-blast inductor and its application to hot-air furnaces.

G

GAGES

Snap. Tools Used in the Manufacture of P & W Adjustable Limit Snap-Gage, Ellsworth Sheldon. Am. Mach., vol. 55, nos. 11 and 12, Sept. 15 and 22, 1921, pp. 428–431 and 456–460, 24 figs. Sept. 15: Accurate alignment a prime requisite. Tool that drills a "cut-out" or crescent-shaped hole. Sept. 22: Making measuring anvils; accurate grinding operations; an ingenious lapping device.

Thread. New Type of Thread Gages, B. M. W. Hanson. Machy. (N. Y.), vol. 28, no. 2, Oct. 1921, pp. 110–111, 3 figs. Describes accurate method of determining correctness of screw threads by vision as well as by touch.

GALVANIZING

Metal-Spray Process. The Metal Spray Process and Its Use in Shipbuilding and Other Industries (Das Metallspritzverfahren und seine Anwendung in Schiffbau und anderen Industrien). Schiffbau, vol. 22, no. 48, Aug. 31, 1921, pp. 1238–1241, 4 figs. Discusses process, and its advantages in shipbuilding technique.

Processes. Metal Coatings as Protection Against Rust (Metallüberzüge als Rostschutzmittel), Werner Lange. Zeit. für Metallkunde, vol. 13, no. 7, Apr. 1921, pp. 161–170, 26 figs. Evaluation of different galvanizing processes, based on corrosion tests carried out by German military authorities during war.

GAS TURBINES

Aeronautical. Turbines and Kindred Problems in Aeronautics (Turbinen und verwandte Probleme in der Flugtechnik), W. G. Noack. Zeitschrift für Flugtechnik u. Motorluftschiffahrt, vol. 11, no. 14, July 31, 1920, pp. 201–207, 8 figs. Investigation of extent to which turbine can be considered as a motor for aircraft, and what prospects exist of applying the driving principle of the turbine, namely, the conversion of the energy of flow into mechanical work, in a more direct manner than is the case with the turbine for forward drive. (To be concluded.)

Holzwarth. The Internal-Combustion Turbine, Mark Meredith. Oil Field Eng., vol. 23, no. 9, Sept. 1921, p. 130. Describes "Holzwarth" oil turbine now being tested at works of Thyssen & Co., Germany; develops 500 hp. at 3,000 r.p.m.

Oil and Gas Turbines. Gas and Oil Turbines (Die Gas- und Oelturbine), W. Schüle. Elektrotechnische Zeit., vol. 42, nos. 29 and 30, July 21 and 28, 1921, pp. 777–784 and 821–824, 12 figs. Some of greatest difficulties in design of gas turbines are enumerated, and author proves by actual tests and operating results that all these problems have been solved and that gas or oil turbines represent serious competitor with steam turbine for either stationary, railway or ship-propulsion purposes. Test data of 500-kw. oil turbine are given.

GASOLINE

Absorption from Casinghead Gas. The Absorption of Gasoline From Casinghead Gas by Activated Charcoal, H. R. Auerswald. Mech. Eng., vol. 43, no. 9, Sept. 1921, pp. 601–602 and 606, 2 figs. Particulars regarding series of tests undertaken to evaluate process when applied to rich gas, with conclusions drawn therefrom as to its limitations.

Natural-Gas. Natural Gas-Gasoline Blends, D. B. Dow. U. S. Bur. Mines Reports of Investigations, serial no. 2279, Sept. 1921, 2 pp. Notes on how it is made. Includes table showing distillations of raw natural gas-gasoline, blending naphthas, and resulting blends.

GASOLINE ENGINES

Mixture Ratio and Temperature. The Effect of Mixture Ratio and Temperature on Power and Economy, C. S. Kegerreis. Automotive Industries, vol. 45, no. 13, Sept. 29, 1921, pp. 610–612, 5 figs. Tests conducted at Purdue Univ. show that marked gains in economy with but trifling loss in power result from proper heating of charge and correct mixture proportions.

GEARS

Compressive Stress. Gearing Calculations by the Compressive Stress Method—I, Joseph Jandasek. Automotive Industries, vol. 45, no. 11, Sept. 15, 1921, pp. 512–515, 15 figs. Maximum surface pressure, or compressive stress, must be considered if rate of wear of tooth is to be kept within proper limits.

Elliptical Wheels. The Design of Elliptical Wheels for a Constant Speed Reciprocating Motion—II, Osbert H. Nichols. Machinery (Lond.), vol. 18, no. 469, Sept. 22, 1921, pp. 754–756, 3 figs. Discusses proportions and effect of elliptical wheels, as used for modifying simple harmonic motion.

Helical. Cutting Rolling Mill Driving Gears. Machinery (Lond.), vol. 18, no. 470, Sept. 29, 1921,

pp. 787–790, 5 figs. Discusses production of large double helical gears by end-milling process.

Involute, Testing. Inspection of Involute Gear Hobs—II, Carl G. Olson. Machy. (N. Y.), vol. 28, no. 2, Oct. 1921, pp. 138–140, 6 figs. Methods used in examining test gears.

GRINDING

Automobile Parts. Grinding in the Automotive Industry—IV, P. M. Heldt. Automotive Ind., vol. 45, no. 9, Sept. 1, 1921, pp. 421–426, 12 figs. Discusses methods used in grinding crankshafts, flat faces, camshafts, gear teeth, splines and other parts. (Concluded.)

GRINDING MACHINES

Internal. Grinding Irregular-Shaped Holes on the Bryant Internal Grinding Machine. Am. Mach., vol. 55, no. 13, Sept. 29, 1921, pp. 499–500, 7 figs. Handling combinations of straight, tapered and curved internal surfaces. Grinding done in one operation. Laying out special control plates.

GUN MOUNTS

16-In. Disappearing Carriage. Design and Construction of the 16-in. Disappearing Carriage from an Engineer's Standpoint, G. M. Barnes. Mech. Eng., vol. 43, no. 10, Oct. 1921, pp. 659–660 and 674, 5 figs. Describes 16-in. high-power gun mounted on disappearing carriage, especially designed for seacoast-defense purposes; gun weighs 170 tons and carriage an additional 670 tons. Details of principal parts and forces acting on members of carriage, and recoil mechanism.

H

HANGARS

Concrete. The Hangar Near Tondern (Luftskibshallen ved Tönder), I. W. Unmack. Teknisk Tidsskrift (Elektroteknisk), vol. 45, no. 31, August 3, 1921, pp. 113–115, 5 figs. Reinforced concrete structure capable of housing two zeppelins. Details of construction and equipment.

Strauss Type. Airplane Shed with Special Roof and Door Construction. Eng. News-Rec., vol. 87, no. 14, Oct. 6, 1921, pp. 565–566, 2 figs. Quick-erection form of steel-roof-truss framing was adopted by designer, J. B. Strauss, and an adaptation of his well-known form of bascule bridge counterweighting was applied to pivoted door which forms one entire end of shed and is 21 ft. high and 100 ft. long.

HARDNESS

Testing. The Hardness Testing of Metals. Mech. Eng., vol. 43, no. 7, July 1921, pp. 445–449, 11 figs. Report of Committee of Engineering Division of Nat. Research Council on various methods of testing hardness of metals.

The Use of the Scleroscope on Light Specimens o Metals, Fred S. Tritton. Inst. Metals advance paper for meeting Sept. 21–22, 1921, no. 8, 10 pp., 4 figs.; also Engineering, vol. 112, no. 2909, Sept. 30, 1921, pp. 492–493, 4 figs. Results of experiments show that usual methods of supporting light specimens of metal for scleroscope test do not give results with accuracy which can be obtained when specimens are supported by methods described.

HEALTH

Plant Medical Department. Practices and Functions of the Medical Department, Robert E. Andrews. Indus. Management, vol. 62, no. 4, Oct. 1921, pp. 206–211, 6 figs. Experiences and procedure in medical department of large textile industry.

HEAT

Dissipation Coefficients of Iron and Copper. Determination of Heat-Dissipation Coefficients (Verfahren zur Bestimmung von Wärmeabgabekoeffizienten), K. Luhowsky. Elektrotechnische Zeit. vol. 42, no. 4, Jan. 27, 1921, pp. 79–81, 4 figs. Heat-dissipation coefficients of iron and copper bodies, in air and in oil, stationary and in motion, influenced by different paints and insulating materials, are determined in watts per sq. cm. for 1 deg. cent. temperature rise. Account of test. Curves and tables, giving test data obtained, are included.

HEAT TRANSMISSION

Buildings. Heat Loss Through Various Types of Building Construction, L. A. Scipio. Jl. Am. Soc. Heating & Ventilating Engrs., vol. 27, no. 6, Sept. 1921, pp. 637–643, 2 figs. Results of series of experiments carried out to determine heat losses from different wall constructions for residence buildings, for which five houses exactly similar with exception of wall material and construction were built and heated by electric stoves for observation.

Furnaces, Losses in. Principles of Heat Loss in Furnaces, P. Rosin. Forging & Heat Treating, vol. 7, no. 8, August 1921, pp. 425–428, 1 fig. Study of heat losses through a furnace wall consisting of at least two different parts, a refractory material and an insulating material. Extract of article from "Metall und Erz."

Liquids. Numerical Laws of Heat Transmission Between Liquids in Industrial Heat Exchangers (Lois numériques de la transmission de la chaleur entre les fluides dans les echangeurs industriels), H. Dieterlen. Chaleur et Industrie, vol. 2, no. 16, August 1921, pp. 494–500, 4 figs. Discusses various formulas in use and finds them contradictory. (Continuation of serial.)

Problems. Solution of Heat Transfer Problems, H. G. Nevitt. Power Plant Eng., vol. 25, no. 17, Sept. 1, 1921, pp. 849–850, 1 fig. Discusses chart for determining mean temperature difference in a heat-transfer problem when initial and final temperature differences are known.

HEAT TREATING

Oil-Burning System. Screw Stock Heat Treated With Oil, F. J. Ryan. Iron Age, vol. 108, no. 11, Sept. 15, 1921, pp. 660–661, 3 figs. Application of Mircs system to ferrous and non-ferrous material by Bridgeport Screw Co. Operating data.

HEATING, STEAM

Boiler Improvements. Fuel Economy in Heating Service, A. Bement. Heat. & Vent. Mag., vol. 18, no. 9, Sept. 1921, pp. 36–38. Comments on present practice in down-draft boiler design with suggestions for improvements.

Vacuum. Vacuum Steam Heating (Vakuumdampfheizung), L. Silberberg. Zeit. des Vereines deutscher Ingenieure, vol. 65, no. 34, Aug. 20, 1921, pp. 898–901, 15 figs. Comparison of different methods of exhaust-steam heating. Description of vacuum heating, and its efficiency in practice. Experimental results.

HELICOPTERS

Types. Helicopters (Les Hélicoptères), L. Guguet. L'Aerophile, vol. 29, no. 13–14, July 1–15, 1921, pp. 209–213, 6 figs. Discusses Austrian army captive type, Oehmichen, Pateras, Pescara, and other types.

HYDRAULIC TURBINES

Installation. The Hydraulic Plant—II, N. L. Devendorf. Power, vol. 54, no. 14, Oct. 4, 1921, pp. 513–516, 6 figs. Types of turbine setting, forms of draft tube, effect of air leakage, vertical vs. horizontal turbines, thrust bearings, maintenance and repairs.

Pelton Wheels. An Experimental Study of the Effect of Roughness of Bucket Surface on the Efficiency of Pelton Wheel, Junzo Nakahara. Jl. Soc. Mech. Engrs. & Soc. Nav. Architects, Sept. 1921. (In Japanese.)

Reaction. Contribution to the Knowledge of Hydraulic Reaction Turbines (Contributo Allo Studio Delle Turbine Idrauliche A Reazione), R. Leonardi. L'Industria, vol. 35, nos. 13 and 14, July 15 and 31, 1921, pp. 296–298, 5 figs. and pp. 314–319, 5 figs. Discusses theory of turbines, especially performance curves. Discussion and calculation of efficiency.

Types. The Hydraulic Plant—I, N. L. Devendorf. Power, vol. 54, no. 13, Sept. 27, 1921, pp. 484–486, 4 figs. Methods of removing débris from water in high- and low-head plants, types of hydraulic turbine employed, their limitations and means for effecting regulation.

HYDROELECTRIC DEVELOPMENTS

Great Britain. Hydro-Electric Developments—I, F. Rowlinson. Beama, vol. 9, no. 3, Sept. 1921, pp. 224–230, 1 fig. Summarizes developments in North Wales, Scotland and Ireland.

HYDROELECTRIC PLANTS

Brazil. Sorocaba Hydro-Electric Plant in Brazil, H. P. Quick. Power, vol. 54, no. 15, Oct. 11, 1921, pp. 548–551, 6 figs. Development planned for 75,000 hp. in five 15,000-hp. turbines operating under a 600-ft. net effective head. Designed and put into successful operation by American engineers.

Kern River, Cal. Automatic Features of New Kern River Power Plant. Eng. News-Rec., vol. 87, no. 11, Sept. 15, 1921, p. 453. Reaction turbines for 810-ft. head have quickly changeable runners. Extensive automatic control equipment.

Manitoba, Canada. New Plant on Winnipeg River. Can. Engr., vol. 41, no. 10, Sept. 8, 1921, pp. 1, 6 and 8 Great Falls development to have capacity of 168,000 hp., with six 28,000-hp. units. Details of head gates, screens, hydraulic turbines, generators, transformers, switching apparatus and transmission lines.

Switzerland. Constructional Details of the Oberhasli Hydroelectric Works (Les dispositions constructives des usines hydro électriques de l'Oberhasli). Bulletin Technique de la Suisse Romande, vol. 47, no. 17, August 20, 1921, pp. 193–198, 7 figs. Discusses hydrographic conditions, construction of dams, reservoirs, etc. (To be continued.)

I

IMPACT

Stress Recorder. Fereday & Palmer's Patent Stress Recorder. Ry. Gaz., vol. 35, no. 7, August 12, 1921, pp. 283–285, 27 figs., partly on supp. pl. Describes an instrument for recording impact stresses on railway bridges by a train passing at high speed.

INDICATORS

Diagrams. Taking Indicator Diagrams, P. A. Baumeister. Power, vol. 54, no. 15, Oct. 11, 1921, pp. 551–552, 4 figs. Points out requirements and necessary steps for getting good indicator diagrams.

Steam-Engine, High-Speed. A New Design of High Speed Engine Indicator, Benno R. Dierfeld. Automotive Ind., vol. 45, no. 10, Sept. 8, 1921, pp. 471–473, 15 figs. German instrument employs steel pencil to trace extremely small diagram on soot-covered glass plate which is enlarged by use of microscope.

INDUSTRIAL MANAGEMENT

Factory Investigations. Economic Value of Factory Investigations, Albert A. Dowd. Machy. (N. Y.), vol. 28, no. 2, Oct. 1921, pp. 121–122. Gives examples of cost reductions resulting from investigations. Improved method of manufacturing a long rod. Notes on handling materials, inspection and salvage, time studies and assembling.

Gantt Charts. The Gantt Chart—III, Wallace Clark. Management Eng., vol. 1, no. 4, Oct. 1921, pp. 225–229, 4 figs. Its application to progress of work.

Intra-Plant Communication. A Development in Intro-Plant Communication, Donald McNicol. Management Eng., vol. 1, no. 4, Oct. 1921, pp. 235–237, 3 figs. Describes how printing telegraph may be employed to supplement telephone in solving problem of plant communication.

Objections Made to. Scientific Management—XXXI, Henry Atkinson. Eng. & Indus. Management, vol. 6, no. 11, Sept. 15, 1921, pp. 286–289. Examination of objections made against scientific management.

Production, Economics of. The Economics of Production—IV, V and VI, D. A. McCabe. Am. Mach., vol. 55, nos. 11, 12, 13 and 14, Sept. 15, 22, 29, and Oct. 6, 1921, pp. 419–420, 455–456, 497–498 and 539–540. Sept. 15: Causes of changes in demand. Sept. 22: Production and reduced demand. Sept. 29: Producer's job and profits. Oct. 6: Production and wages.

Production Methods. Modern Production Methods—XXI, XXII and XXIII, W. R. Basset. Am. Mach., vol. 55, nos. 11, 13 and 15, Sept. 15, 29 and Oct. 13, 1921, pp. 421–423, 501–505 and 604–608, 13 figs. Sept. 15: Graphic methods of control; when to use graphic charts and when not to; master charts. Sept. 29: Various uses of time studies; attitude of workman; some general rules for time-study observer. Oct. 13: Records of actual time studies of machine operations; fallacy of taking over-all times for standards.

Protection Control by Graphics, Fred R. Daniels. Machy. (N. Y.), vol. 28, no. 2, Oct. 1921, pp. 112–120, 14 figs. System employing graphic charts for controlling shop operations, in use in plant of Hopedale Mfg. Co., Milford, Mass.

Production Planning. Quality and Costs as Standards of Production (Güte und Kosten als Grundmassstäbe der Produktion), H. Basson. Betrieb, vol. 3, no. 22, Aug. 13, 1921, pp. 695–703, 12 figs. States that quality and cost of product are influenced by fitness of design and quality of materials used, as well as by accuracy of production, etc. Based on practical examples, errors in design, possibilities for economizing in material, and accuracy of production are discussed.

Works Organization, R. Waring-Brown. Eng. & Indus. Management, vol. 6, no. 14, Oct. 6, 1921, pp. 377–382, 9 figs. Production engineer's planning department in automobile factory.

Purchasing Organization. Purchasing Organization in Machine Works (Beitrag zur Frage der Einkaufsorganisation in Maschinenfabriken), E. Springorum. Betrieb, vol. 3, no. 21, July 25, 1921, pp. 682–687, 13 figs. Purchasing system is described according to which departments making use of purchased material share responsibility.

Routing. Routing Work in Factories for Series Production with Numerous Separate Parts and Erection Groups (Die Abwicklung der Werkaufträge in Fabriken für Serienfabrikation mit sehr vielen Einzelteilen und Montagegruppen), H. Fürstenau. Betrieb, vol. 3, no. 21, July 25, 1921, pp. 665–674, 10 figs. Describes system for smooth flow of production and gives examples of its application in manufacture of railway cars. It can be applied to manufacture of locomotives, motor plows, automobiles, ships, etc.

Charting Routing Losses. Factory, vol. 27, no. 3, Sept. 1921, pp. 328–329, 2 figs. Graphic method of locating source of trouble. Experience of Am. Optical Co.

Simplification. Simplification in Industry—VII, Howard Coonley. Factory, vol. 27, no. 3, Sept. 1921, pp. 317–319, 4 figs. How line was reduced from 17,000 to 610 items. Describes how simplification facilitated development of suitable budget of business and opened way to other advantages.

Small Shop. Organization and Management of the Small Shop—V, VI and VII, E. W. Leach. Am. Mach., vol. 55, nos. 11, 13 and 15, Sept. 15, 29 and Oct. 13, 1921, pp. 438–441, 513–516, and 592–595, 7 figs. Sept. 15: Production planning and control. Necessity and uses of system. Figuring shop capacity. Simple method of cost-keeping. Sept. 29: Value of cost records; what profit should be based upon. Classification of material and labor accounts; overhead and what it consists of. Oct. 13: Filling customer's order; necessity of keeping records; efficiency in shipping room.

Stock-Record Keeping. Worth While Considerations in Stock Record Keeping, F. E. Merriam. Indus. Management, vol. 62, no. 4, Oct. 1921, pp. 199–205, 9 figs. Defines duties and scope of stock-record department, and its relation to management.

Tracing Materials. Making It Easy to Trace Materials, L. E. Dodd. Factory, vol. 27, no. 3, Sept. 1921, pp. 330–332, 5 figs. Plan for recording material in factory that readily permits tracing it back to its source or ahead to its ultimate destination. Developed in Optical Glass Plant of Nat. Bur. of Standards, Pittsburgh and Washington.

[See also MOTION STUDY.]

INDUSTRIAL ORGANIZATION

Knitting Mills. The Organization of Knitting Mills, Carle M. Bigelow. Management Eng., vol. 1, no. 4, Oct. 1921, pp. 193–198, 4 figs. Notes on solving problems of specialized industry.

INDUSTRIAL RELATIONS

Human Factor. The Human Factor in Industry—I,

grew above the machine.

INDUSTRIAL TRUCKS

Hydraulic. The L.A.C. Hydraulic Truck, George F. Zimmer. Eng. & Indus. Management, vol. 6, no. 14, Oct. 6, 1921, pp. 385–387, 3 figs. Describes truck consisting of a main and sub-frame, former supported by four wheels 9 in. in diam. and 3 in. wide. Hydraulic lifting device consists of two cylinders and operating valves, formed together in gun-metal casting.

INSPECTION

Delco System. The Delco Inspection System. Machinery (Lond.), vol. 18, no. 460, July 21, 1921, pp. 468–471, 8 figs. Description of methods used in tool and gage-designing department of Dayton Eng. Laboratories Co. and standards of gaging adopted.

INTERNAL-COMBUSTION ENGINES

Frictional Losses. Distribution of Frictional Losses in Internal Combustion Engines, E. P. Taylor. Gas & Oil Power, vol. 16, no. 192, Sept. 1, 1921, pp. 190–192. Describes a number of tests and concludes that the retardation method offers the advantages of accuracy and complete speed range with the disadvantage that values of friction are obtained under special conditions. (From Jl. Proc. Roy. Soc. of New South Wales.)

Fuel, Valves and Ignition. The Internal-Combustion Engine: Fuel, Valves, and Ignition, A. W. Bradbury. Mech. Wld., vol. 70, no. 1809, Sept. 2, 1921, p. 193. Discusses chemical and mechanical work done in combustion chamber. (To be continued.) From paper read before Inst. Mar. Engrs.

Fuels, Influence of. The Influence of Various Fuels on Engine Performance—VI, H. R. Ricardo. Automotive Industries, vol. 45, no. 10, Sept. 8, 1921, pp. 465–470, 6 figs. Outlines tests intended to determine conditions which govern ease of starting with various fuels and effect of fuel upon volumetric efficiency. (To be continued.) From preliminary report conducted for Asiatic Petroleum Co.

The Influence of Various Fuels on the Performance of Internal Combustion Engines—VII, H. R. Ricardo. Automobile Engr., vol. 11, no. 153, August 1921, pp. 279–284, 5 figs. Gives tables of fuel characteristics and experimental results for variable compression engines.

Two- and Four-Cycle. The Internal Combustion Engine Discussed, A. W. Bradbury. Power House, vol. 14, no. 17, Sept. 5, 1921, pp. 32–36, 14 figs. Discusses two-cycle and four-cycle types, their advantages and disadvantages. Read before Inst. Mar. Engrs.

[See also AEROPLANE ENGINES; AUTOMOBILE ENGINES; DIESEL ENGINES; GASOLINE ENGINES; OIL ENGINES.]

IRON

Stainless. Stainless Iron. Times Eng. Supp., no. 563, Sept. 1921, p. 257. A variant of stainless steel, mechanical properties, corrosion and errosion.

IRON AND STEEL

Microscopic Examination. Microscopic Examination of Iron and Steel. Chem. & Met. Eng., vol. 25, no. 10, Sept. 7, 1921, pp. 471–472. Report of committee appointed by Am. Soc. for Testing Materials on methods for testing iron and steel.

L

LABOR TURNOVER

Causes. Why Men Quit, H. L. Keely. Indus. Management, vol. 62, no. 4, Oct. 1921, pp. 223–227, 3 figs. Simple method of recording caused, classifying them, and making record of practical use to management.

LATHES

Bench. Bench Lathes and Millers as Production Tools. Machy. (N. Y.), vol. 28, no. 2, Oct. 1921, pp. 130–134, 9 figs. Examples of work regularly manufactured on bench machines by B. C. Ames Co., Waltham, Mass.

Large. A Very Large Lathe. Engineer, vol. 132, no. 3430, Sept. 23, 1921, pp. 325–326, 3 figs., two on supp. plate. Describes sliding, surfacing and screw-cutting lathe built by Thomas Shanks & Co., Johnstone. Principal dimensions are: Height of centers without packing, 111 in.; and with packing, 123 in.; admit between centers, 40 ft.; width of slide bed, 18 ft. 6 in.; overall length of bed, 60 ft.; diam. of face-plate, 15 ft.; main motor, 120 hp.

Motor-Driven Heavy. Recent Machine Tool Developments—XXI, Joseph Horner. Engineering, vol. 112, no. 2906, Sept. 9, 1921, pp. 364–367, 12 figs. Motor-driven heavy lathe of 20-in. centers, constructed by Francis Berry & Sons, Sowerby Bridge, England.

Turret. Improving Tool Equipments, Hubert Bentley. Eng. & Indus. Management, vol. 6, no. 10, Sept. 8, 1921, pp. 265–266, 3 figs. Describes hexagon turret toolholder, use of which, it is claimed, increases productivity of machine and prolongs life of tool.

Production Work in the Locomotive Shop—I. Machy. (N. Y.), vol. 28, no. 2, Oct. 1921, pp. 102–105, 10 figs. Application of Bullard vertical turret lathe to locomotive-shop practice, with typical examples and description of tooling for each job.

44 figs. partly on supp plate. Details of automatic turret lathe constructed by Gisholt Machine Co., Madison, Wis. Swing of lathe is 20 in., maximum distance between chuck and turret is 45 in. and maximum length of work which can be handled 14 in.; overall length, 11 ft. 10⅝ in.; weight, 10,100 lb. It can be driven by electric motor or belt.

Vertical. An Original Type of Lathe. Eng. Production, vol. 3, no. 49, Sept. 8, 1921, pp. 219–220, 1 fig. Details of vertical lathe made by Cadillac Tool Co., Detroit, which can be used for turning, facing and grooving operations.

LIQUIDS

Viscosity. Effect of Temperature on the Viscosity of Liquids (Influence de la température sur la viscosité des liquides normaux), Edm. van Aubel. Comptes Rendus des Séances de L'Académie des Sciences, vol. 173, no. 7, August 16, 1921, pp. 384–387. Gives new formula and shows that it is accurate with normal liquids.

LOCOMOTIVES

Booster Tests. Booster Tests on Temiskaming & Northern Ontario. Ry. Age, vol. 71, no. 10, Sept. 3, 1921, pp. 447–448, 4 figs. Results of tests of locomotive boosters show 20 per cent increased freight tonnage and rapid acceleration of passenger trains.

British. The Comparison of Dimensions and Proportions of British Locomotives, E. C. Poultney. Ry. Mech. Engr., vol. 95, no. 9, Sept. 1921, pp. 539–542, 1 fig. Discusses factor of adhesion, rated tractive effort, boiler factor, factors of combustion, firebox volume, efficiency, etc. (To be continued.)

Coaling Stations. Concrete Coaling Station. Engineer, vol. 132, no. 3428, Sept. 9, 1921, pp. 271–273, 3 figs. Plant of moderate size built at engine yard and running sheds of Phila. & Reading R. R., Philadelphia. Conveyor is intermittent vertical hoist, with single bucket of 3 tons capacity; both coal and sand for engines are handled by same apparatus. Reinforced-concrete structure consists of tower with hoisting shaft and a 600-ton storage bin which span two lines of rails.

New Coaling Stations on the Santa Fe. Ry. Elec. Engr., vol. 12, no. 9, Sept. 1921, pp. 334–337, 5 figs. Description of 400-ton reinforced-concrete automatic electric coaling and sanding plant permitting continuous operation of buckets.

Design and Operation. The Necessity for Improvement in the Design and Operation of Present-Day Locomotives, H. W. Snyder. Mech. Eng., vol. 43, no. 7, July 1921, pp. 455–458, 1 fig. Brief discussion of engine problems, followed by consideration of design of main and side rods and crankpins to withstand tremendous piston thrust to which they are subjected in large engines; problem of counterbalancing; frame design and cross-bracing; driving-box brasses; ashpan design, lubrication, etc.

4-6-0 Express Goods. Four-Cylinder Express Goods Locomotives on the Great Central Railway. Ry. Gaz., vol. 35, no. 10, Sept. 2, 1921, pp. 368–369, 2 figs. Type 4–6–0, tractive effort 29,507 lb. at 85 per cent boiler pressure.

4-6-0 Three-Cylinder. New Three-Cylinder 4–6–0 Type Locomotives, Caledonian Railway. Ry. Gaz., vol. 35, no. 13, Sept. 23, 1921, pp. 463, 2 figs. on page 464. Three 8½-in. single-expansion cylinders, six coupled wheels of medium diameter, and 60 tons of adhesion.

Freight. Advantages of Large Freight Locomotives. Particularly the 2–10–2 Type, Albert F. Stuebing. Mech. Eng. vol. 43, no. 7, July 1921, pp. 459–460. Points out more important considerations involved in study of economic value of various types of motive power and demonstrates complexity of problem.

Liquid Fuel. On the Utility of Studying the Question of the Use of Liquid Fuel in Locomotives, Henry Fowler. Bul. International Ry. Assn., vol. 3, no. 8, August 1921, pp. 923–976, 11 figs. Discusses a number of questions sent to R. R. administrations on their using liquid fuel and gives tabulated statement of replies received.

Mikado. New Locomotives for the Missouri Pacific. Ry. Age, vol. 71, no. 11, Sept. 10, 1921, pp. 495–498, 4 figs. Data on Mikado type equipped with booster, switcher, Pacific and mountain types.

Oil Firing. Oil-Firing on English Railways, E. C. Bowden-Smith. Petroleum Times, vol. 6, no. 139, Sept. 3, 1921, pp. 617–618, 1 fig. Describes working of a Great Central tank locomotive burning oil.

Superheater. Three-Cylinder Superheated Steam Goods Train Locomotive. Type 2–10–0, G. Heise. Eng. Progress, vol. 1, no. 5, May 1920, pp. 191–195, 25 figs. Describes types built by Lokomotiv-Bauanstalt Henschel & Sohn.

2-8-0 Belgian State Railways. Powerful New 2–8–0 Type Locomotives For the Belgian State Railways. Ry. Gaz., vol. 35, no. 7, August 12, 1921, pp. 286–287, 5 figs. Built by Armstrong, Whitworth & Co., for mixed traffic; develops tractive force of 45,820 lb.

Weighing Plant. A Large Capacity Locomotive Weighing Plant, Carl C. Bailey. Ry. Age, vol. 71, no. 10, Sept. 3, 1921, pp. 453–455, 5 figs. Heavy scale is housed in special building with equipment for determining wheel loads.

LUBRICATION

Car Journals. Lubrication of Car Journals Without the Use of Waste. Ry. Rev., vol. 69, no. 9, August 27, 1921, pp. 267–271, 6 figs. Particulars of tests conducted to determine relative advantages of splash-oil lubrication vs. waste-packed method.

MACHINE SHOPS

Design and Construction. The Design and Construction of Engineering Workshops—XXII, Ernest G. Beck. Mech. Wld., vol. 70, no. 1810, Sept. 9, 1921, pp. 202–203, 2 figs. Continuation of discussion on construction of roofs.

Haarlem, Holland. A Visit to the Haarlem Machine Works, Formerly Figee Bros. (Bezoek aan de fabrieksterreinen Noorder Buiten Spaarne van de Haarlemsche Machine-fabriek, voorheen Gebrs. Figee), P. J. Van Zwieten. De Ingenieur, vol. 36, no. 35, August 27, 1921, pp. 664–677, 23 figs. Describes development of works and some of its principal construction work carried out.

MACHINE-TOOL INDUSTRY

Influence of Automobile on. The Influence Exerted by the Automobile on the Machine-Tool Industry. Mech. Eng., vol. 43, no. 8, Aug. 1921, pp. 529–534, 1 fig. Group of papers by F. K. Hendrickson, Henry J. Eberhardt, Henry J. Hinde, Ralph E. Flanders and Chester B. Lord, dealing with changes brought about by automobile in machine-tool design, construction and operation, together with discussion of fundamentals of interchangeable manufacture.

MACHINE TOOLS

Special vs. Standard. Manufacturing with Special Machines vs. Standard Equipment—V, G. F. Jenks and M. H. Christopherson. Am. Mach., vol. 55, no. 12, Sept. 22, 1921, pp. 475–479, 12 figs. Lapping cylinders; testing and assembling. Comparison of machining times at Otis Works and Water town Arsenal.

MAGNESIUM ALLOYS

Electron Metal. The Magnesium Alloy "Electron," S. Beckinsale. Inst. Metals advance paper for meeting Sept. 21–22, 1921, no. 12, 2 pp. Note on results of examination of samples, of German origin, of magnesium alloy known as electron.

MALLEABLE IRON

American. American Malleable Cast Iron—XIX, H. A. Schwartz. Iron Trade Rev., vol. 69, no. 13, Sept. 29, 1921, pp. 813–816, 1 fig. Inspection and testing.

MANGANESE STEEL

Carbonizing. Carbonizing Manganese Steel, A. A. Blue. Forging & Heat Treating, vol. 7, no. 8, August 1921, pp. 413–415, 4 figs. States that increased manganese content produces greater sensitiveness to carbonizing.

MARINE ENGINES

Broken Propeller Blades. Examples of Broken Propeller Blades of Marine Engines, S. Sasaki. Jl. Soc. Mech. Engrs. & Soc. Nav. Architects, Sept. 1921. (In Japanese.)

MARINE STEAM TURBINES

Diaphragms. Turbine Diaphragms, H. M. David. Mech. Wld., vol. 70, no. 1809, Sept. 2, 1921, pp. 181–183, 7 figs. Examines question from mechanical and constructional point of view; discusses type applying more particularly to marine turbines of impulse type having double reduction gear.

Geared. Double-Reduction Gearing of the Three-Case Type for Steamships. Engineering, vol. 112, no. 2906, Sept. 9, 1921, p. 376, 2 figs. on supp. plate. Constructed by Scotts Shipbuilding & Eng. Co., Ltd., Greenock, England, for single-screw vessel; transmits 6000 shaft hp.; high-pressure and low-pressure turbines have speed of 3,000 and 18,000 r.p.m., respectively.

Angular Vibrations in Marine Propelling Machinery, Richard Gardner. Engineering, vol. 112, no. 2906, Sept. 9, 1921, pp. 363–364, 3 figs. Investigation of vibration effect in relation to geared steam-turbine installations. Proposes method for obtaining comparative estimates of outside limits to amplitude of vibration in gearing.

METAL SPRAYING

Schoop Process. The Schoop Process of Metal Spraying. Am. Mach., vol. 55, no. 16, Oct. 20, 1921, pp. 647–648, 6 figs. Protective coating of metal sprayed by compressed air. Impalpable particles discharged at high velocities penetrate pores. Variety of metals can be used.

METALLOGRAPHY

Etching. A New Etching Medium for Chrome and Tungsten Steels (Ein neues Aetzmittel für Chrom- und Wolframstähle), Karl Daeves. Stahl u. Eisen, vol. 41, no. 36, Sept. 8, 1921, pp. 1262–1264, 3 figs. Describes composition of new etching medium containing yellow prussiate of potassium, adapted to etching of high-speed tool steel, and other purposes.

The Electrolytic Etching of Metals, Frank Adcock. Inst. Metals advance paper for meeting Sept. 21–22, 1921, no. 11, 9 pp., 18 figs. Notes on citric acid solution; ammonium molybdate solution; method of etching cupro-nickel (80:20) so as to show both cores and grain boundaries. Notes on gold. Heat etching of platinum.

METALS

Alkaline. Experiences with the Alkaline and Alkaline Earth Metals in Connection with Non-Ferrous Alloys, Charles Vickers. Am. Electrochemical Soc. advance paper no. 14, for Meeting, Sept. 29–Oct. 1, 1921, pp. 191–198. Sodium, of the alkaline metals, is said to serve as suitable deoxidizing agent in producing copper castings of superior torsional

strength; calcium, of alkaline earth metals, when in combination with an acid element, as silicon, produces castings of good electrical conductivity.

Fatigue. The Fatigue of Metals, Clifford W. Nash. Commonwealth Engr., vol. 8, no. 12, July 1, 1921, pp. 250–353. Discusses fatigue and elastic limit, endurance limit, mechanism of fatigue failure, and conditions favoring resistance to fatigue.

Rigidity and Viscosity. The Effect of Temperature on the Modulus of Rigidity, and on the Viscosity of Solid Metals, Kei Iokibe and Sukeaki Sakai. Lond., Edinburgh, and Dublin Philosophical Mag. & Jl. Sci., vol. 42, no. 249, Sept. 1921, pp. 397–418, 17 figs. Gives results of experiments carried out with 13 different metals to measure rigidity and logarithmic decrement at ordinary and high temperatures.

MICROMETERS

Accuracy. Checking the Accuracy of Micrometer Measurements, Ellsworth Sheldon. Am. Mach., vol. 55, no. 14, Oct. 6, 1921, pp. 562–564. Notes on close measurements with micrometer; possibilities of error due to mechanical defects.

Recording Ultra-. The Recording Ultra-Micrometer, John J. Dowling. Engineering, vol. 112, no. 2906, Sept. 9, 1921, p. 395, 1 fig. States that both in physical laboratory and engineering, measurement of minute strains, displacements, expansions and the like, can be carried out with a degree of refinement altogether out of proportion with simplicity and reliability of apparatus. All measurements can be made from a distance and can be recorded by a recording galvanometer if desired. Paper read before British Assn. at Edinburgh.

MILLING CUTTERS

Forged High-Speed. Characteristics of the Forged Milling Cutter, William G. Galkins. Am. Mach., vol. 55, no. 11, Sept. 15, 1921, pp. 424–427, 10 figs. Methods of manufacture. Results of casting and forging high-speed steel. Structure of metal. Comparison of bar stock and forged steel.

MOLYBDENUM STEEL

Constituents. On Constituents Found in Tungsten and Molybdenum Steels, Albert M. Portevin. Iron & Steel Inst. advance proof for meeting Sept. 5–6, 1921, no. 5, 4 pp., 6 figs.; also Engineering, vol. 112, no. 2906, Sept. 9, 1921, pp. 372–373, 6 figs. As results of systematic investigation of special steels author has been able to effect disappearance of obviously hard states (martensitic or austenitic), and to establish fact that certain structures which might have been regarded as being in equilibrium, are superseded by others which represent an even more advanced state of equilibrium.

MOTION STUDY

Photographic Apparatus for. Photographic Apparatus for Motion Study (Hilfsmittel für Bewegungsuntersuchungen), R. Thun. Betrieb, vol. 3, no. 24, Sept. 5, 1921, pp. 771–779, 10 figs. Discusses motion pictures and photographic bases for time-motion studies. Describes apparatus for the taking and evaluation of motion pictures and compares two different kinds of motion photographs.

MOTOR PLOWS

German Ergomobil. The Ergomobil Motor Plow (Der Ergomobil-Motorseilpflug), A. Schilling. Oel- u. Gasmaschine, vol. 18, nos. 6, 7 and 8, June, July and Aug., 1921, pp. 96–97, 115–117 and 123–126, 15 figs. Details of rope-transmission plow with single-cylinder internal-combustion-engine drive, constructed by A. Borsig, Ltd., Berlin-Tegel.

Types. Motor-Driven Ploughs, Dr. Martiny. Eng. Progress, vol. 2, no. 8, August 1921, pp. 169–174, 21 figs. Discusses application of motor-driven plows; describes Stock, Wede, Hansa-Lloyd types.

MOTOR TRUCKS

Advantages. Trucks Pass the Tests of the Times, F. W. Fenn. Power Wagon, no. 202, September 1921, pp. 15–17 and 37. Gives figures showing decrease of horse traffic and increase of motor trucks, and gives examples of advantages of latter.

Dump Bodies. Making Dump Bodies for Motor Trucks. Iron Age, vol. 108, no. 15, Oct. 13, 1921, pp. 937–938, 2 figs. Specialized factory unit of Van Dorn Iron Works Co. arranged for convenience and economy in handling materials. Shipping room is abolished.

MOTORCYCLES

Engines. Machining Motor Cycle Engines. Eng. Production, vol. 3, no. 48, Sept. 1, 1921, pp. 205–210, 15 figs. Methods of J. A. Prestwich & Co., Ltd., Tottenham, London.

N

NICKEL ALLOYS

Nickel-Aluminum-Copper. The Properties of Some Nickel-Aluminium-Copper Alloys, A. A. Read. Inst. Metals advance paper for meeting Sept. 21–22, 1921, no. 1, 24 pp., 23 figs.; also Engineering, vol. 112, no. 2908, Sept. 23, 1921, pp. 453–456, 22 figs. Continuation of work described in Jl. Inst. Metals (vol. 11, no. 1, 1914, p. 169) in course of which a type of alloy was observed which, while extremely soft and ductile on quenching from 900 deg. cent., was considerably hardened by cooling. In present work the properties of alloys of this type are investigated more fully.

NOZZLES

Diffuser, Tests of. Tests with Diffusers ([Ueber Versuche mit Verdichtungsdüsen (Diffusoren)], August Riffart. Zeit. des Vereines deutscher Ingenieure, vol. 65, no. 35, Aug. 27, 1921, pp. 918–922, 44 figs. A diffuser is a wedge-shaped pipe section for conversion of flow velocity into pressure. Whereas in conversion of pressure into velocity efficiency of 96 to 98 per cent has been obtained, the reverse is possible only with great loss. Writer seeks to determine causes therefor based on phenomena of flow.

O

OIL ENGINES

Injection Type. The Rising Importance of Oil-Injection Type of Internal-Combustion Engine, Charles E. Lucke. Mech. Eng., vol. 43, no. 10, Oct. 1921, pp. 653–658 and 686, 24 figs. Review of development of internal-combustion engine from early gas-burning type to present-day injection engine capable of operating on any form of liquid fuel without explosive shock.

Marine. Some Observations on Marine Oil Engines, D. M. Shannon. Mech. Wld., vol. 70, no. 1808, August 26, 1921, pp. 163–164, 3 figs. Discusses systems of oil injection and states that for large marine engines the favorite mechanical injection system consists in having a common pressure main in which oil is kept at 3000 to 4000 lb. and to which all fuel valves are connected. (Continued.) Paper read before Inst. Mar. Engrs.

Piston Temperature Measurements. Temperature Measurements of Oil-Engine Pistons (Temperaturmessungen an Kolben von Oelmaschinen), W. Riehm. Zeit. des Vereines deutscher Ingenieure, vol. 65, no. 35, Aug. 27, 1921, pp. 923–925, 7 figs. Direct measurement of temperatures of uncooled pistons in Diesel engines under different operating conditions. Temperature distribution in piston heads of different shapes.

Still. Still Oil Engine for Marine Propulsion. Engineering, vol. 112, no. 2905, Sept. 2, 1921, pp. 344–345, 2 figs. Brief description of engine followed by extracts of report by deputation of French engineers of tests on experimental engine designed and built by Scotts' Shipbuilding & Eng. Co., Ltd., Greenock, England.

Vegetable-Oil Fuel. Using Vegetable Oils in Hot-Bulb Engines (Essais sur l'utilisation des huiles végétales dans les moteurs a boule chaude), M. Mathot. Bulletin Technique du Bureau Veritas, vol. 3, no. 7, July 1921, pp. 167–169. Results of tests show that with palm and cotton oil a hp-hour requires 265 grams in a 4-stroke 25-hp. engine, 320 grams in a 2-stroke 16-hp. engine, 285 grams in a 2-stroke 33-hp. engine, etc. Paper read before Association pour le perfectionnement du materiel colonial, at Brussels.

OIL FUEL

Chemical Research. The Role of the Chemist in Relation to the Future Supply of Liquid Fuel, Harold Hibbert. Jl. Industrial & Eng. Chem., vol. 13, no. 9, Sept. 1921, pp. 841–843. Discusses alcohol, saccharifying organisms, and sources other than alcohol. Read before Am. Chem. Soc.

Installations. The Installation of Oil as Fuel, Allen F. Brewer. Power, vol. 54, no. 10, Sept. 6, 1921, pp. 361–364, 1 fig. Suggestions for selection of suitable equipment.

Mexican. The Production and Combustion of Mexican Fuel Oil—V and VI, J. M. Pettingell and J. R. Carlson. Combustion, vol. 5, nos. 3 and 4, Sept. and Oct. 1921, pp. 110–114, 6 figs. and 168–175, 6 figs. Describes features common to oil-burning plants and successful practice; various types of burners and furnaces.

Production and Use. Fuel Oil: Its Production and Use, W. A. Whyte. Petroleum Times, vol. 6, no. 133, July 23, 1921, pp. 133–135. Discusses Mexican oils, physical tests, etc. (Concluded.)

Vegetation. Motor Fuel from Vegetation, T. A. Boyd. Jl. Industrial & Eng. Chem., vol. 13, no. 9, Sept. 1921, pp. 836–841, 6 figs. Discusses shale, benzene, alcohol and cellulose as sources of motor fuel. Read before Am. Chem. Soc.

OILS

Linseed. A Study on the Oil Bromide Test of Linseed Oil, Thomas A. Davidson. Jl. Industrial & Eng. Chem., vol. 13, no. 9, Sept. 1921, pp. 801–806. Finds that the centrifuge is most satisfactory for separating oil bromides from reaction mixture, and volatility of either proved no drawback.

Viscosity. Viscosity-Temperature Curves of Fractions of Typical American Crude Oils, E. W. Dean and F. W. Lane. Jl. Industrial & Eng. Chem., vol. 13, no. 9, Sept. 1921, pp. 779–786, 7 figs. Determines curves for products derived from Pennsylvania, California and Wyoming crude oils.

Viscosity of Engine Oils, O. W. Franke. Power Plant Eng., vol. 25, no. 17, Sept. 1, 1921, pp. 847–848. Greasy friction is essential for reciprocating engines.

OPEN-HEARTH FURNACES

Acid. Acid Open-Hearth Practice (Der saure Martinofenbetrieb). Stahl u. Eisen, vol. 40, nos. 34 and 35, Aug. 26 and Sept. 2, 1920, pp. 1129–1135 and 1165–1170, 15 figs. on supp. plate. Refers to two works by B. Yaneske, and J. H. Whiteley and A. F. Hallimond, respectively, in Jl. Iron & Steel Inst. (vol. 99, no. 1, 1919), both based on the physical-chemical phase rules. Notes on presence of ferric oxide in furnace; regulation of degree of acid in slag; addition of lime; physical conditions during smelting; removal of carbon due to oxidation through gas; reaction between metal and slag; etc. (To be concluded.)

Design. Open-Hearth Furnace Design, A. D. Williams. Iron Age, vol. 108, no. 12, Sept. 22, 1921, pp. 719–721, 6 figs. Reversing valves and their effect on efficiency. Chimney areas and heights.

P

PAINTS

White Lead. Paints, Painting and Painters, With Reference to Technical Problems, Public Interests and Health, Henry E. Armstrong. Jl. Roy. Soc. Arts, vol. 69, no. 3588, August 26, 1921, pp. 655–682 and (discussion) 682–685, 4 figs. Discusses suggested prohibition of white lead; volatilization of lead and turpentine; volatile constituents of paint removers; risks and dangers due to mechanical operation; etc. Is against government interference.

PATTERNS

Storage. The Organization of Pattern Stores, H. Varley. Eng. & Indus. Management, vol. 6, no. 14, Oct. 6, 1921, pp. 374–376, 3 figs. Account of organization of stores shows how economy in time, money and labor may easily be effected by introduction of suitable system.

PISTON RINGS

Design. Important Factors in Piston-Ring Design, H. H. Platt. Jl. Soc. Automotive Engrs., vol. 9, no. 3, Sept. 1921, pp. 195–197 and (discussion) 197–199, 1 fig. Discusses diagonal and lap joints, design for gas tightness, oil leakage.

POWER GENERATION

Steam, Fuel Economy in. Fuel Economy by the Adoption of Scientific Management in Steam Generation and Utilisation, David Brownlie. Eng. & Indus. Management, vol. 6, no. 14, Oct. 6, 1921, pp. 393–394 and 396. Discusses cause of losses in steam generation, low-temperature carbonization, and flue-gas analysis.

POWER PLANTS

Design. Developments in Power Station Design—VI–XI. Engineer, vol. 132, nos. 3426, 3427, 3428, 3429, 3430, 3431, Aug. 26, Sept. 2, 9, 16, 23 and 30, 1921, pp. 214–216, 8 figs., pp. 234–235, 7 figs., pp. 258–260, 8 figs., pp. 282–284, 9 figs., pp. 324–325, 5 figs. and pp. 336–338, 6 figs. Aug. 26: The Scarab and Babcock oil burners. Sept. 2: The Thornycroft oil fuel burners; the White low-pressure system; the Lawton steam jet burner. Sept. 9: The Alldays & Onions, and White oil burners, and the Wilton burner for burning of all classes of liquid fuel. Sept. 16: Electrical distance thermometers and CO_2 recorders. Sept. 23: Describes Tozer retort for low-temperature carbonization of bituminous coal. Sept. 30: Tozer low-temperature carbonization power plant for South African Carbide & By-Products Co., Natal, with retorts, steam turbine and electric plant.

Economic Operation. The Economic Operation of Small Power Plants, Malcolm C. W. Tomlinson. Management Eng., vol. 1, no. 4, Oct. 1921, pp. 199–204, 4 figs. How to reduce wastage of coal, steam, water, electric power, and compressed air.

Evolution. Power-Plant Evolution, C. F. Hirshfeld. Mech. Eng., vol. 43, no. 9, Sept. 1921, pp. 575–578. Discusses decrease brought about in cost of producing electric power, and of possibilities of further increasing plant efficiencies by use of higher steam pressures, air preheating, improved methods of feedwater heating, etc.

Ford Plant, River Rouge. New Ford Power Plant at River Rouge, Thomas Wilson. Power, vol. 54, no. 9, Sept. 6, 1921, pp. 348–353, 9 figs. Plant featured by large double-ended boilers having 26,470 sq. ft. of steam-making surface and burning simultaneously blast-furnace gas and powdered coal; complete electrical system and unique substation layout.

Toledo, Ohio. Acme Power Plant at Toledo. Power, vol. 54, no. 12, Sept. 20, 1921, pp. 434–442, 13 figs. A 200,000-kw. ultimate-capacity generating station, of which 40,000 kw. in two units has been installed. Prominent features of station are said to be coal handling, water supply, boiler room with unusual facilities for metering and control, and switchhouse.

PRESSES

Spring-Clip, Manufacture. Press Tools for the Manufacture of Spring Clips, J. J. Holloway. Machinery (Lond.), vol. 18, no. 469, Sept. 22, 1921, pp. 765–766, 6 figs. Describes operation of each tool.

Uses. Cutting Costs with the Power Press, Edward K. Hammond. Machy. (N. Y.), vol. 28, no. 2, Oct. 1921, pp. 96–101, 9 figs. How material and labor are saved by use of power presses.

PROFIT SHARING

Disadvantages. Thrift Encouragement by Employers—IV, Leonhard Felix Fuld. Indus. Management, vol. 62, no. 4, Oct. 1921, pp. 214–215. Writer explains his objections to profit-sharing dividends.

PULVERIZED COAL

Advantages and Disadvantages. Commission on Fuel Utilization (Commission d'Utilisation du Combustible). Revue de L'Industrie Minérale, no. 15, August 1, 1921, pp. 514–519. Third report Minister of Public Works. Discusses firing with pulverized coal and summarizes advantages and disadvantages.

Application. Application of Pulverized Coal (Renseignements sur l'emploi du charbon pulvérisé), Pierre Appell. Chaleur et Industrie, vol. 2, no. 16, August 1921, pp. 510–512. Gives results of tests made in boiler burning 200 kg. per hour.

Boilers. Powdered Coal Under Steam Boilers—III, H. D. Savage. Coal Trade Jl., vol. 52, no. 38,

of pulverized-fuel combustion.

Colloidal Mixtures. Pulverised Coal and Colloidal Mixtures, L. C. Harvey. Eng. & Indus. Management, vol. 6, no. 11, Sept. 15, 1921, pp. 310–312. Discusses merits and general features of pulverized coal and its admixture with liquid fuel.

Furnaces for Electrical Works. Pulverized-Coal Furnaces for Electrical Works (Kohlenstaubfeuerungen für Elektrizitätswerke), Friedrich Münzinger. Elektrotechnische Zeit., vol. 42, no. 5, Feb. 3, 1921, pp. 97–103, 10 figs. Systematic review and critical investigation of prospects of different construction types of pulverized-coal furnaces, especially from operative and economic viewpoint. Notes on preparation plant; combustion of pulverized coal; and adaptability of pulverized-coal furnaces for stationary steam boilers. Abstract of book entitled Pulverized-Coal Furnaces for Stationary Steam Boilers, published by J. Springer, Berlin.

Plant. Development of a Powdered Coal Plant, Charles Longenecker. Blast Furnace & Steel Plant, vol. 9, no. 9, Sept. 1921, pp. 567–569. Discusses grade of coal, powdered-coal equipment and furnace changes.

PUMPS

Air-Lift. Experiments on Air Lift Pumping, John S. Owen. Engineering, vol. 112, no. 2908, Sept. 23, 1921, pp. 458–461, 9 figs. Describes experiments made with view to ascertaining most efficient design for air-lift pump, for lifting acid mine liquors in mine in San Domingos, Portugal. Describes installation finally adopted, and gives lists of tests showing that it is quite possible to get pump efficiencies with air lifts of between 60 and 70 per cent. Paper read before British Assn.

PUMPS, CENTRIFUGAL

Flood-Proof Pump House. Novel Condenser Pump House. Elec. Ry. Jl., vol. 58, no. 11, Sept. 10, 1921, pp. 387–391, 9 figs. American Railways power plant at Kenova, W. Va., recently enlarged in capacity, now derives circulating water from new electrically driven centrifugal pumps, housed in a structure which is designed to be floodproof.

R

RAILS

Fissures. Causes of Fissures in Street-Railway Rails (Ursachen der Riffelbildung auf Strassenbahnschienen), P. Oberhoffer. Stahl u. Eisen, vol. 41, no. 33, Aug. 18, 1921, pp. 1137–1141, 14 figs. on supp. plate. Discusses results of tests (shown in tables) carried out on different makes of rails of the Berlin street railway, from which it is concluded that the character of section has a greater influence than quality of material used.

Grooved, Wear of. The Alternating Contact Action Between Car-Wheel Flanges and Grooved Rails on Curves (Die Wechselwirkung zwischen den Berührungskreisen des Räderpaares und des Bogengleises beim Rillenschienenoberbau), F. Hartmann. Verkehrstechnik, vol. 38, no. 19, July 5, 1921, pp. 294–295, 13 figs. Shows that where both flanges are in contact with groove sides, the layout is such that the wear and tear is only half as great as usual.

RAILWAY ELECTRIFICATION

Austria. Electrification of the Austrian Federal Railway (Einführung der elektrischen Zugförderung auf den österreichischen Bundesbahnen), C. Wlach. Elektrotechnische Zeit., vol. 42, no. 20, May 19, 1921, pp. 505–511, 8 figs. Abstract of officially accepted electrification program of Austrian Republic. It is expected to finish four main branches before end of 1925. Description of Austrian main roads which are to be electrified, together with description and sketches of four types of locomotives, all of which are 15,000-volt, 16²/₃-cycle a.c. machines.

France. French Railways Electrification—V and VI. Elec. Ry. & Tramway Jl., vol. 44, nos. 1072 and 1077, April 8 and May 13, 1921, pp. 164–165. April 8: Classification of locomotives according to axle arrangement. May 13: Three-phase system as applied to Simplon line, single-phase system as applied to Swiss Railways, and continuous current at high tension.

Holland. Railways Electrification in Holland. Elec. Ry. & Tramway Jl., vol. 45, no. 1095, Sept. 9, 1921, pp. 171–173. Concludes that electrification must be on the direct-current system and a 1500-volt working tension. Report of special commission.

Italy. Electrification Progress on Italian Railways, Giovanni B. Santi. Ry. Age, vol. 71, no. 10, Sept. 3, 1921, pp. 439–442, 6 figs. A number of hydroelectric plants are under construction, as fuel is expensive and hard to obtain.

Switzerland. Electrification Program of the Swiss Federal Railroads (Programme d'électrification des chemins de fer Fédéraux et consequences financières du remplacement de la traction a vapeur par la traction électrique). Bulletin Téchnique de la Suisse Romande, vol. 47, no. 18, Sept. 3, 1921, pp. 208–211, 5 figs. Compares cost of traction of trains at various prices of coal. (Concluded.)

The Electrification of the Swiss Federal Railways—I and II. Engineer, vol. 132, nos. 3431 and 3432, Sept. 30 and Oct. 7, 1921, p. 335 and 376–377, 1 fig. Abstract of paper by L. Thorman dealing with technical side of electric traction for main lines in so far as it affects electrification of Swiss Federal Railway. Points out successful use of 15,000-volt single-phase current in Switzerland.

RAILWAY OPERATION

Cost of Stopping Trains. The Cost of Stopping train resistance and analyzes cost of stopping.

Freight Traffic, Unit Cost Data for. Unit Cost Data For Freight Traffic. Ry. Gaz., vol. 35, no. 13, Sept. 23, 1921, pp. 458 and 462. Discusses simple method of recording work of freight and mixed trains in order to get ton-mile costs quickly.

Train Control. Train Control Problems Discussed in England. Ry. Signal Engr., vol. 14, no. 9, Sept. 1921, pp. 336–342. Problems of Automatic Train Control by W. J. Thorrowgood; Automatic Train Control by J. Beaumont; Elimination of Frost Trouble by E. W. Kolb; Stop or Proceed vs. Stop and Proceed by A. H. Rudd.

RAILWAY SIGNALING

Electric. Maintenance of A. C. Signal Apparatus, L. F. Viellard. Ry. Signal Engr., vol. 14, no. 9, Sept. 1921, pp. 347–350. Describes experience with a.c. signals and interlockers on Long Island R. R.

Principles of Alternating Current Signaling—VI, J. S. Holliday. Ry. Signal Engr., vol. 14, no. 9, Sept. 1921, pp. 350–352, 2 figs. Vector solutions of correct transformer voltage and distribution of energy between signal motor, slot-coil and lamps.

Position-Light Signal. New Design of Position Light Signal. Ry. Age, vol. 71, no. 12, Sept. 17, 1921, pp. 538–539, 3 figs. Discusses new Pennsylvania R. R. signaling system worked day and night by uncolored electric lights.

RAILWAY TIES

Machine for Cutting and Boring. Cross-Cutting, Adzing and Boring Machine for Railway Sleepers. Engineer, vol. 132, no. 3431, Sept. 30, 1921, pp. 353–354, 4 figs. partly on p. 348. Built by Indian State Railways by Thos. Robinson & Son, Ltd., Rochdale.

RAILWAY TRACK

Construction. On the Question of the Construction of the Road Bed and of the Track, E. F. C. Trench. Bul. International Ry. Assn., vol. 3, no. 8, August 1921, pp. 991–1086, 15 figs. Report deals with Great Britain, India, South Africa, Australia and New Zealand. Gives a large appendix containing answers to question from railways. Concludes that present conditions are satisfactory.

Maintenance. On the Question of the Maintenance and the Supervision of the Track, Earl Stimson. Bul. International Ry. Assn., vol. 3, no. 8, August 1921, pp. 977–990. Concludes that high costs are due to causes beyond the control of supervisory organizations; advises most direct contact between maintenance-of-way engineer and division engineer.

RAILWAYS

France. The Great French Railroad Lines in 1920 (Les résultats de l'exploitation des grands réseaux français de chemins de fer en 1920). Révue Générale des Chemins de Fer, vol. 40, no. 9, Sept. 1921, pp. 141–167. Discusses income and expenditure, rolling stock, traffic, fuel, wages, of the Nord, Est, P.L.M., P.O., Midi and Etat lines, giving numerous tables.

REDUCTION GEARS

Machining. Machining Turbine Reduction Gears. Machinery (Lond.), vol. 18, no. 460, July 21, 1921, pp. 481–483, 6 figs. Discusses methods adopted by W. Beardmore & Co. Dalmuir, Scotland.

REFRACTORIES

Physical Characteristics. Physical Characteristics of Specialized Refractories, M. L. Hartmann and W. A. Koehler. Am. Electrochemical Soc., advance paper no. 9, for Meeting, Sept. 29–Oct. 1, 1921, pp. 129–136, 1 fig. Series of tests to determine transverse breaking strength of each of ten refractories, at 20 and 1350 deg. cent. Chrome brick showed most decided drop in modulus of rupture, followed in order by bauxite, magnesia, fireclay and silica.

REFRIGERATING PLANTS

Fulton Market, Chicago. Fulton Market Cold Storage Plant, Chicago. Power, vol. 54, no. 13, Sept. 27, 1921, pp. 470–473, 4 figs. Describes economical synchronous-motor-driven refrigerating plant to have eventually 10,500,000 cu. ft. of storage space and 888 tons of refrigerating capacity. Compressors are two-stage machines with injection of liquid between stages and pipe coil in intermediate drum to precool ammonia liquor on its way to brine coolers.

Pipe for. Pipe for Refrigeration Systems. Southern Engr., vol. 36, no. 1, Sept. 1921, pp. 50–54, 8 figs. Discusses dependability, bursting pressure, threading principle of pipe, etc.

Reconstruction. Reconstruction of Ice and Cold Storage Plant. Ice & Refrigeration, vol. 61, no. 2, August 1921, pp. 91–93, 7 figs. Sherman Ice Co. Sherman, Texas.

Turbo-Compressor. Calculation of Turbo-Compressor Refrigerating Plant (Intorno al calcolo degli impianti frigoriferi a vapore d'acqua azionati da turbo-compressori), Luigi M. Brunelli. L'Industria, vol. 35, no. 15, August 15, 1921, pp. 334–337, 2 figs. Discusses Leblanc turbo-compressors and its application to refrigeration.

ROLLING MILLS

Matching and Doubling Machine. Mechanical Matcher Lowers Cost. Iron Trade Rev., vol. 69, no. 15, Oct. 13, 1921, pp. 948–950, 5 figs. Manual work involved in aligning and doubling hot rolled sheets is performed by motor-driven machine. Device designed by Lawrence C. Steele, Pittsburgh, is said to offer increased production.

108, no. 14, Oct. 6, 1921, pp. 859–864, 7 figs. Prominent features of new rolling mill in Chicago is pack cooling bed, said to be first installation of its kind in industry, and hot runout table, all rollers having individual motor drive, those next to bed being of swiveled cone type. See also article on same subject by George H. Manlove in Iron Trade Rev., vol. 69, no. 14, Oct. 6, 1921, pp. 869–873 and 880, 10 figs.

Plate Mills. A Plate Mill in Norway, Wilh. Krämer. Eng. Progress, vol. 1, no. 7–8, July–August 1920, pp. 267–270, 2 figs. Describes equipment and working processes of A. S. Norsk Valseverk's installation.

Roll Design. The Logic of Roll Design—V, W. H. Melaney. Blast Furnace & Steel Plant, vol. 9, no. 9, Sept. 1921, pp. 543–545, 3 figs. Proportion of wabbler to size of neck for various type mills is considered.

Rotary Piercing Machines. The Rotary Piercing Machine for Steel and Copper Billets, C. E. Davies. Engineering, vol. 112, nos. 2907, 2908, 2910 and 2911, Sept. 16, 23, Oct 7 and 14, 1921, pp. 397–399, 429–430, 495–496 and 527–528, 25 figs. Writer seeks to outline satisfactory theory for rotary piercer. Description and theory is obtained from translation of article published in Stahl u. Eisen (Sept. 1919), to which a short summary with remarks on design and use of rotary piercer in England are added.

Sheet Mills. The Possibility of Improved Methods of Rolling Sheet Steel, Sumner B. Ely. Mech. Eng., vol. 43, no. 10, Oct. 1921, pp. 670–671. Points out importance of proper heating in sheet-steel rolling and discusses possibility of a continuous sheet mill. Describes a successful Austrian continuous sheet mill.

RUBBER

Aging Tests. Ten Years' Experience With Aging Tests, William C. Geer. India Rubber Wld., vol. 64, no. 10, Sept. 1, 1921, pp. 887–892, 15 figs. Describes test that can be used for predicting probable effect of natural aging upon vulcanized rubber. Paper read at International Rubber Conference, Lond.

Substitutes. Rubber Substitutes and the Role They Play in Vulcanisation, D. H. Priestley and H. Skellon. Rubber Age, vol. 2, no. 7, Sept. 1921, pp. 351–352. Discusses unsaturated oils and oxydized oils, dark substitutes and white substitutes.

Vulcanization. Influence of Certain Organic Accelerators on Vulcanization of Rubber, George Stafford Whitby and Osman James Walker. Jl. Industrial & Eng. Chem., vol. 13, no. 9, Sept. 1921, pp. 816–819, 4 figs. Influence of 1 per cent of (a) piperidine piperidyl-dithocarbamate (b) hexamethylenetetramine, and (c) thiocarbanilide on the rate of vulcanization of a 90:10 rubber-surface mix etc. Presented before Am. Chem. Soc.

S

SAFETY ENGINEERING

Education in. Education in Safety Engineering as Given at the Lynn General Electric Engineering and Apprentice School, N. M. DuChemin. Safety Eng., vol 42, no. 3, Sept. 1921, pp. 106–112. Outline of lessons presented in ten lectures.

SCIENTIFIC MANAGEMENT

See INDUSTRIAL MANAGEMENT

SHAPERS

Production Work, Use in. Production Shaping—I. Machy. (N. Y.), vol. 28, no. 2, Oct. 1921, pp. 89–93, 5 figs. Use of shapers in production work for planing column and table castings for Avey drilling machine.

SPECIFIC HEAT

Apparatus. New Specific Heat Apparatus, Ezer Griffiths. Physical Soc. of Lond. Proc., vol. 33, no. 190, August 15, 1921, pp. 355–361, 3 figs. Describes apparatus for determination of specific heat of cork, charcoal, etc., difficult to deal with by ordinary methods.

Lead. The Behaviour of Substances Near The Absolute Zero, William R. Fielding. Chemical News, vol. 123, no. 3201, August 19. 1921, pp. 97–99, 1 fig. Discusses specific heats of lead and gives tables for lead, water and copper.

STANDARDIZATION

German N.D.I. Report. Report of the German Industry Committee on Standards (Mitteilungen des Normenausschusses der Deutschen Industrie). Betrieb, vol. 3, no. 21, July 25, 1921, pp. 319–330, 14 figs. Accepted standards: Blank castel nuts, standard screw heads and points. Proposals of Board of Directors for cotter and taper-pin nut locking devices; sizes for technical photographic prints; proposed standards for steel window sash; concrete sewer pipes.

Report of the German Industry Committee on Standards (Mitteilungen des Normenausschusses der Deutschen Industrie). Betrieb, vol. 3, no. 22, Aug. 13, 1921, pp. 339–348, 16 figs. Proposals of Board of Directors for relative temperature of measuring tools and workpieces; drive and sunk keys, flat keys, saddle keys, fitted and sliding feather keys, gibhead keys, gibhead flat and saddle keys. Proposed standards for belt-pulley diameters; speeds for transmission gears; graphic representation by means of curves.

Report of the German Industry Committee on Standards (Mitteilungen des Normenausschusses der Deutschen Industrie). Betrieb, vol. 3, no. 23, Aug. 27, 1921, pp. 355–360, 7 figs. Proposals of

ENGINEERING INDEX (Continued)

Board of Directors for pressure stages for pipe lines; wires and cables for high-voltage overhead lines. Proposed standards for drawings.

STEAM

Flow Measurement. Steam Flow Measurements from a Boiler, C. T. Mitchell. Power, vol. 54, no. 9, Aug. 30, 1921, p. 318. Points out importance of constant pressure as regards accuracy of steam-flow records, and develops simple formula for calculating amount of steam given off by boiler for given pressure drop, independently of fuel consumption.

High-Pressure. High Pressure Steam in Small Power Plants—III, Charles L. Hubbard. Sanitary & Heating Eng., vol. 96, no. 7, Sept. 23, 1921, pp. 199–201, 9 figs. Disclosing functions and principles of steam specialties used in conjunction with power plants, and explaining their mechanical operations (To be continued.)

Specific Heat. The Various Determinations of the Specific Heat of Steam and Their Technical Significance, H. Schmolke. Mech. Eng., vol. 43, no. 10, Oct. 1921, pp. 675–677. Account of experiments carried out over pressure range of 2 to 8 atmos. and with temperatures ranging from around saturation to 350 deg. cent., and other investigations. Translated from Zeit. für Dampfkessel u. Maschinenbetrieb, vol. 44, nos. 1 and 2, Jan. 7 and 14, 1921.

STEAM ENGINES

Throttle Valves. Throttle Valves for Steam Engines, W. H. Wakeman. Power, vol. 54, no. 10, Sept. 6, 1921, pp. 372–373, 7 figs. Various types.

Uniflow. Straight-Flow High-Lift Poppet-Valve Steam Engine, J. Stumpf. Mech. Eng., vol. 43, no. 8, Aug. 1921, pp. 541–542, 6 figs. Describes engine in which, it is claimed, losses due to cylinder condensation, clearance space, throttling, friction, leakage, heat radiation, heat conduction and imperfect expansion are reduced. Its most characteristic element is said to be the very small high-lift nozzle-disk valve employed therein. Translated from Zeit. des Vereines deutscher Ingenieure, vol. 65, no. 19, May 7, 1921.

200 Hp. Uniflow Steam Engine. Engineer, vol. 132, no. 3426, Aug. 26, 1921, pp. 222–224, 5 figs. Describes engine constructed by Galloways, Ltd., Manchester, England, most novel features of which are said to be shockless high-speed valve gear and a compression release device designed by Henry Piling.

STEAM GENERATION

Waste-Heat Utilization. Waste Heat Utilization For Steam Generation, G. R. McDermott. Assn. Iron & Steel Elec. Engrs., vol. 3, no. 9, Sept. 1921, pp. 293–319, 7 figs. Gives particulars of tests with waste heat boilers and discusses sources of waste gases, including those from large gas engines.

STEAM GENERATORS

Electric. An Electric Steam-Generator For Low Voltage, F. A. Lidbury and F. A. Stamps. Am. Electrochemical Soc., advance copy, no. 4, pp. 77–86, 2 figs. Describes an inexpensive form of apparatus for the generation of steam by means of alternating current of voltages from 100 to 500. (Abstract.)

STEAM PIPES

Resistance Reduction. Savings Effected by Reducing the Resistance in Steam Pipe Lines (Ersparnisse durch Verminderung der Widerstände in Dampfleitungen), O. Denecke. Zeit für Dampfkessel u. Maschinenbetrieb, vol. 44, no. 26, July 1, 1921, pp. 201–204, 2 figs. Total pressure reduction through friction and various resistances. Determination of diameter of pipe with given pressure reduction for any given resistances. Curve is given with which it is possible to read pipe diameter for any steam volume, pipe length, variation of pressure and of the various resistances.

STEAM POWER PLANTS

Condensation in Turbine Room. Condensation in Turbine Rooms of Steam Power Stations, L. J. Towne. Stone & Webster Jl., vol. 29, no. 3, Sept. 1921, pp. 119 225. Condensation on walls and ceilings especially inconvenient during winter months. How condensation occurs and fundamental principles which will prevent or minimize this trouble.

Buick Motor Co. The New Buick Plant. Power Plant Eng., vol. 25, no. 17, Sept. 1, 1921, pp. 835–845, 14 figs. Describes coal-handling equipment, engine and boiler room, wood-burning equipment and electric equipment of Buick Motor Co., a subsidiary of General Motors Corp.

Hydraulic-Relay. Requirements in the Design of Steam Power Stations for Hydraulic Relay, E. B. Powell. Mech. Eng., vol. 43, no. 10, Oct. 1921, pp. 650–652 and 674, 6 figs. Flow or head deficiency type of relay; effect of growth of load, seasonal variation of flow and pondage; relay stations for minimum flow development and for higher-load-factor conditions. Emergency reserve type of relay.

Oil-Burning. Efficient Operation of Oil-Burning Steam Plants, C. H. Delany. Mech. Eng., vol. 43, no. 9, Sept. 1921, pp. 603–605, 4 figs. Discussion of plant characteristic diagram, with particulars regarding its use in establishment of standard of performance and in increasing plant efficiency.

STEAM TRAPS

Types. Steam Traps—Types, Principles of Operation, Selection, Installation, Troubles, Remedies, L. A. H. Merrihew. Power, vol. 54, no. 10, Sept. 6, 1921, pp. 378–381, 4 figs. Savings by proper use of traps; advantages and disadvantages of each type.

STEAM TURBINES

Bleeder. Estimating Steam Consumption of Bleeder Turbines, Joseph Gershberg. Power, vol. 54, no. 15, Oct. 11, 1921, pp. 556–557, 1 fig. Explains convenient method of estimating steam consumption at given load and with given amount of steam being bled.

Curtis Impulse. Efficiency Tests of a 30,000 kw. Turbine, Herbert B. Reynolds. Power House, vol. 14, no. 16, August 20, 1921, pp. 21–25 and 27, 8 figs. Turbines are of Curtis impulse type having twenty pressure stages. Gives tables of turbine, condenser and dry-vacuum-pump tests.

Design. Recent Developments in Steam Turbine Design, C. J. Everett. Trans. S. African Inst. Elec. Engrs., vol. 12, part 7, July 1921, pp. 131–142, 10 figs. Discusses impulse type; Curtis impulse; reaction type; radial-flow type; steam, shaft, and disk packings; blading; etc.

Developments. Some Recent Developments in Large Steam Turbine Practice, K. Baumann. Jl. Instn. Elec. Engrs., vol. 59, no. 302, June 1921, pp. 565–623 and (discussion) 623–663, 49 figs. Part I—Discusses general trend of development, reaction turbines, impulse turbines, turbines for special purposes. Part II—Discusses reliability, working conditions, thermodynamic efficiency, overall dimensions, weights and costs in connection with turbine design. Part III—Economic rating of a given turbine frame. Part IV—Maximum output of turbines at a given speed. Part V—Governing of steam turbines. Part VI—Steam consumption guarantees and test results of large turbines. Part VII—Operation experience with large turbines.

Efficiency Tests. Efficiency Tests of a 30,000-Kw. Steam Turbine, Herbert B. Reynolds. Mech. Eng., vol. 43, no. 7, July 1921, pp. 450–454 and 460, 8 figs. Account and results of tests carried out during 1920 on General Electric turbines at 59th St. power station of Interborough Rapid Transit Co., New York City. These turbines are of straight Curtis impulse type, having 20 pressure stages, each pressure stage consisting of one velocity stage; speed is 1500 r.p.m.

Foundations. Steam Turbine Foundations of Reinforced Concrete (Dampfturbinen-Fundamente aus Eisenbeton), Paul Müller. Bauingenieur, vol. 2, nos. 16 and 17, Aug. 31 and Sept. 15, 1921, pp. 436–439 and 474–478, 14 figs. Writer seeks to determine influence of dynamic action of turbo-compressors and generators on their foundations, and recommends basic form for such foundations which, with minimum use of material, is qualified to withstand all such unfavorable influences.

Heat Balance. Heat Balance with House Turbine. Power, vol. 54, no. 10, Sept. 6, 1921, pp. 382–383, 2 figs. Layout of system for obtaining heat balance with house turbine.

High-Capacity. Steam Turbines for Maximum Loads, A. Loschge. Mech. Eng., vol. 43, no. 9, Sept. 1921, pp. 607–608, 2 figs. Discusses magnitudes which determine value of maximum output of turbine, technical difficulties which have to be overcome in order to make a higher output possible, and ways and means adopted by various concerns to overcome these difficulties. Translated from Zeit. des Vereines deutscher Ingenieure, vol. 65, no. 28, July 9, 1921.

Safe Operation. Safety Precautions in the Operation of Large Turbines. Power, vol. 54, no. 10, Sept. 6, 1921, pp. 354–357, 5 figs. Practical pointers on avoiding turbine injury due to spindle deflection, blade rub, dummy rub and other causes, together with rules for starting and stopping large turbines.

[See also MARINE STEAM TURBINES.]

STEEL

Bars, Specification for. British Standard Specification for Steel Bars for the Production of Machined Parts. British Eng Standards Assn., no. 32, May 1921, 13 pp., 4 figs. Specification of bars for production of machined parts suitable for automatic, semi-automatic and turret lathes. Tables of round, square and hexagon bars; Appendix giving forms of British standard tensile test pieces.

Coalescence in. Contributions to the Study of Coalescence in Steels and Its Commercial Results, Albert Portevin and Victor Bernard. Iron & Steel Inst. advance proof for meeting Sept. 5–6, 1921, no. 6, 35 figs., 10 figs. Experiments are said to afford abundant evidence of influence of initial structural state on solution of cementite during heating, on its precipitation on cooling, and therefore on general result of quenching.

Corrosion. Rust Prevention by Slushing, Haakon Styri. Am. Electrochemical Soc. advance paper no. 8, for Meeting, Sept. 29–Oct. 1, 1921, pp. 113–128. It is shown that a prerequisite for protection against rust by greases is a thorough cleaning of steel parts by an aqueous solution, preferably by oil emulsion which leaves a thin oil film for short time protection.

Damascene. Damascene Steel, N. T. Belaiew. Iron & Steel Inst. advance proof for meeting Sept. 5–6, 1921, no. 1, 4 pp., 1 fig.; also Engineering, vol. 112, no. 2906, Sept. 9, p. 395, 1 fig. In author's opinion a marked analogy exists in structure and in some of properties of high-speed and damascene steels, and a comparative study of both is presented.

Elasticity. On the Temperature Coefficient of the Modulus of Longitudinal Elasticity of Steel, H. M. Dadourian. Lond., Edinburgh, and Dublin. Phil. Mag. & Jl. Sci., vol. 42, no. 249, Sept. 1921, pp. 442–448. Reviews work done on the subject and describes additional experiments.

Fatigue Resistance. Fatigue Resistance of Steel under Repeated Combined Stresses, Akimasa Ono. Jl. Soc. Mech. Engrs. & Soc. Nav. Architects, Sept. 1921. (In Japanese.)

Fracture. Woody Fracture in Steel (Ein Beitrag zur Frage des Holzfaserbruches im Stahl), J. Hanny. Stahl u. Eisen, vol. 41, no. 37, Sept. 15, 1921, pp. 1298–1300. Shows how in production of gun steel, it was possible to prevent formation of woody fracture, through measures based on assumption that inclusions of carbon-monoxide bubbles originating in oxides are the cause of such formations.

Mechanical Properties. An Experimental Investigation of the Mechanical Properties of Steels at High Temperatures, E. L. Dupuy. Engineering, vol. 112, nos. 2906 and 2907, Sept. 9 and 16, 1921, pp. 391–394 and 427–428, 33 figs.; also Iron & Steel Inst. advance proof, Sept. 1921, no. 2, 22 pp., 33 figs. Determination of mechanical properties of steels in respect of their carbon percentages, at all temperatures between normal and incipient fusion. Experiments were carried out on both cast and rolled material.

Physics in. New Discussion on the Physics of Steel, Wm. R. Webster. Blast Furnace & Steel Plant, vol. 9, no. 9, Sept. 1921, pp. 555–563. Application in rolling of effects of carbon, phosphorus and manganese on mechanical properties of steel.

Special. On the Question of Special Steels, M. Sand. Bul. International Ry. Assn., vol. 3, no. 8, August 1921, pp. 1103–1107. Discusses trials with cast manganese steel and Edelstahl cast-steel crossings, also Sandberg process applied to rails of basic open-hearth high-silicon steel.

Tensile Tests. Elongation and Gauge Length in Tensile Tests, J. H. G. Monypenny. Engineer, vol. 132, no. 3426, Aug. 26, 1921, pp. 220–221, 2 figs. Results of series of comparative tests on a large series of steels to see if it were possible to fix some approximate relationship for commercial use between values obtained on British standard test piece on one hand and French and German types on the other.

Testing. Test for Shock Strength of Hardened Steel, C. E. Margerum. Forging & Heat Treating, vol. 7, no. 9, Sept. 1921, pp. 488–490, 3 figs. Describes apparatus to determine ability to resist impact and gives curves of various impact strength tests. Paper presented before Am. Soc. for Testing Materials.

The Influence of the Width of the Specimen Upon the Results of Tensile Tests of Mild Steel and Rolled Copper, T. Hudson Beare and William Gordon. Engineering, vol. 112, no. 2906, Sept. 9, 1921, pp. 389–391, 6 figs. Results of experiments show that, as final thickness is shown to be practically constant for all widths of specimen, decline in percentage of reduction of area is due to gradual diminution in proportional reduction of width. Paper read before British Assn. in Edinburgh.

The Influence of the Width of the Specimen Upon the Results of Tensile Tests of Mild Steel and Rolled Copper, T. Hudson Beare and William Gordon. Metal Industry (Lond.), vol. 19, no. 12, Sept. 16, 1921, pp. 209–212, 6 figs. Details of experiments carried out. Paper read before British Assn.

Worked, Structure of. Structure of Worked Steel as Shown by Etched Sections (Kraftwirkungsfiguren in Flusseisen, dargestellt durch ein neues Aetzverfahren), Ad. Fry. Stahl u. Eisen, vol. 41, no. 32, Aug. 11, 1921, pp. 1093–1097, 19 figs. Describes new etching process which, under certain conditions, reveals peculiar, heretofore unobserved figures; and the brittleness of iron at blue heat is traced to these phenomena.

[See also ALLOY STEEL; CHROME-NICKEL STEEL; MANGANESE STEEL; MOLYBDENUM STEEL; STEEL, HIGH-SPEED.]

STEEL, HEAT TREATMENT OF

Annealing. A Metallographic Characteristic for the Determination of the Pre-Heating of Soft Low-Carbon Steel (Ueber ein metallographisches Kennzeichen für die Ermittlung der vorangegangenen Glühbehandlung von weichem Flusseisen), P. Oberhoffer. Stahl u. Eisen, vol. 41, no. 35, Sept. 1, 1921, pp. 1215–1217, 8 figs. Describes characteristic in structure which makes it possible to determine whether annealing has taken place between Ac_1 and Ac_3.

Cast Steel. The Thermal Treatment of Cast Steel, Alvin N. Conarroe. Trans. Am. Soc. for Steel Treating, vol. 1, no. 12, Sept. 1921, pp. 746–757, 35 figs. Concludes that steel castings can be refined by heat treatment to possess physical characteristics comparable to forgings; also considers inclusions, segregation, shrinkage, etc.

Characteristic Curves. The "Characteristic Curves" of the Heat Treatment of Steels, Albert M. Portevin and Pierre Chevenard. Iron & Steel Inst., advance proof for meeting Sept. 5–6, 1921, no. 7, 19 pp., 11 figs. So-called characteristic curves combine, within a single diagram, fundamental data of every possible heat treatment, and also afford a means of defining accurately the annealed and hardened states of the particular steel.

Drop Forgings. Effect of Heat-Treatment on Steel Castings and Drop Forgings, A. A. Blue. Am. Mach., vol. 55, no. 11, Sept. 15, 1921, pp. 413–418, 26 figs. Results of tests at different stages in heat treatment. Chemical analyses and their results.

Hardened Carbon Steel. Thermal and Physical Changes Accompanying the Heating of Hardened Carbon Steels, Howard Scott and H. Gretchen Movius. Trans. Am. Soc. for Steel Treating, vol. 1, no. 12, Sept. 1921, pp. 758–774, 12 figs. Discusses in detail the transformations in steel below the A_1 change.

Overheating, Effect of. Effect of Overheating High Carbon Steel, Lancelot W. Wild. Blast Furnace & Steel Plant, vol. 9, no. 9, Sept. 1921, pp. 541–542. Heating to the completion of the magnetic change before quenching gives strongest, toughest, best wearing and best cutting steel.

Quenching. Cooling Oil for Quenching Tanks, S. E. Derby. Iron Trade Rev., vol. 69, no. 11, Sept. 15, 1921, pp. 674–676, 5 figs. Proper speed of

ENGINEERING INDEX (Continued)

cooling steel is said to be determining factor in attaining degree of hardness; after determining best temperature of medium, it should be maintained by suitable cooling system.

Steel Castings. Heat Treating Improves Castings, Martin M. Rock. Iron Trade Rev., vol. 69, no. 11, Sept. 15, 1921, pp. 677–679. Tensile tests of unannealed, annealed, air-cooled and water-quenched steel castings do not disclose marked difference in strength, but impact tests show water-quenched product excels other three.

Stresses. Stresses Resulting from Heat Treatment (Das Entstehen von Spannungen bei der Wärmebehandlung), W. Tafel. Stahl u. Eisen, vol. 41, no. 38, Sept. 22, 1921, pp. 1321–1328, 13 figs. It is shown that every heat treatment of a spherical, prismatic or cylindrical body changes its state of stress, based on which the principal deformations in connection with hardening are derived and conclusions arrived at relative to annealing and hardening of steel.

Tempering. Changes Taking Place in Steels During Tempering (Sur la nature des transformations qui se produisent pendant la trempe des aciers), M. P. Dejean. Revue de Métallurgie, vol. 18, no. 7, July 1921, pp. 419–427, 7 figs. Discusses critical points in cooling of nickel steel, carbon steel, manganese steel, etc.

On the Tempering Phenomena of Steels (Remarque et observations concernant les phénomènes de trempe des aciers), Portevin and P. Chevenard. Revue de Metallurgie, vol. 18, no. 7, July 1921, pp. 428–444, 16 figs. Discusses cooling and elongation curves, cementite formation, etc. in ferro-nickel system.

Volume Changes. Volume Changes in the Heat Treatment of Steel, Leslie Aitchison. Trans. Am. Soc. for Steel Treating, vol. 1, no. 12, Sept. 1921, pp. 734–737, 2 figs. Gives curves showing alterations in volume during heating and cooling.

STEEL, HIGH-SPEED

Heat Treatment. Heat Treatment of High Speed Steel, J. L. Thorne. Trans. Am. Soc. for Steel Treating, vol. 1, no. 12, Sept. 1921, pp. 727–732 and (discussion) 732–733. Discusses composition, influence of principal elements, and various stages of heat treating.

Metallurgy of. The Metallurgy of High Speed Steel, D. M. Giltinan. Trans. Am. Soc. for Steel Treating, vol. 1, no. 12, Sept. 1921, pp. 716–726, 10 figs. Discusses present requirements of high-speed steels to meet demand for increased production without increased cost; theories of self-hardening.

STEEL WORKS

Anti-Friction Bearings. Anti-Friction Bearings in the Steel Mill, A. M. MacCutcheon. Assn. Iron & Steel Elec. Engrs., vol. 3, no. 9, Sept. 1921, pp. 321–350, 16 figs. Discusses advantages and disadvantages of anti-friction and oil ring type of bearings, development of ball and roller bearings, mounting of anti-friction bearings and experiences in various mills.

Fuel Requirements. Fuel Requirements of Steel Mills, F. E. Leahy. Assn. Iron & Steel Elec. Engrs., vol. 3, no. 9, Sept. 1921, pp. 427–435. Discusses application of solid, gaseous and liquid fuels, also pulverized coal.

Railway Electrification. Electrification of the Steel Plant Railroad, R. B. Gerhardt. Assn. Iron & Steel Elec. Engrs., vol. 3, no. 9, Sept. 1921, pp. 277–291. Concludes that electric motor will displace steam engine just as happened in rolling mills.

STOKERS

Capacity and Limitations. Capacity and Efficiency Limitations of Stokers Using Mid-West Coals, John E. Wilson. Mech. Eng., vol. 43, no. 8, Aug. 1921, pp. 536–537 and 561. In case of natural-draft chain-grate stokers, greatest losses are said to be those due to dry chimney gases and carbon in ash. Capacity is governed principally by available draft and ratio of total boiler heating surface to grate area. Notes on use of underfeed and overfeed forced-draft stokers in Mid-West.

Limitations. Limitations of Mechanical Stokers Utilizing Mid-West Coals, Edward H. Tenney. Mech. Eng., vol. 43, no. 8, Aug. 1921, pp. 535–536. Points out that Mid-West coals are characterized by higher moisture, volatile and ash contents as compared with Eastern coals. Discusses limitations imposed by air supply and by design of furnace; and effect of these various limitations on stoker operation. (Abstract.)

Low-Grade Fuel. Stoking Inferior Fuels, A. Wirth. Eng. Progress, vol. 2, no. 8, August 1921, pp. 185–189, 27 figs. Discusses grates, traveling stokers, removal of slag and ashes.

Traveling Grate Regulators. Speed Regulators for Traveling Grates (Geschwindigkeitsregler für Wanderroste), H. Generlich. Zeit. des Vereines deutscher Ingenieure, vol. 65, no. 36, Sept. 3, 1921, pp. 943–944, 5 figs. Describes device for automatic regulation of speed of grate.

SUPERHEATED STEAM

Use in Sugar Factories. The Employment of Superheated Steam in Sugar Factories, E. de Bernard. La. Planter & Sugar Mfr., vol. 47, no. 13, Sept. 24, 1921, p. 202, 1 fig. Points out that in order to employ superheated steam, it is necessary to have separate boilers for supplying machine developing motive power and for supplying steam to evaporators, as then different pressures in both cases may be developed.

SUPERHEATERS

Design and Calculation. Steam Superheaters: Their Design, Construction, Application and Use, H. B. Oatley. Mech. Eng., vol. 43, no. 10, Oct. 1921, pp. 663–669, 15 figs. Fundamentals of design and materials used. Characteristics and details of locomotive, marine and stationary superheaters. Operating conditions where reciprocating or rotating prime movers used superheated steam. Results obtained by using superheated steam.

T

TEMPERATURE MEASUREMENT

Radiation of Energy. The Measurement of Temperature—XIV, P. Field Foster. Mech. World, vol. 70, no. 1811, Sept. 16, 1921, pp. 225–226, 3 figs. Discusses radiation, or transmission, of energy without the aid of intervening matter. (To be continued.)

TERMINALS, LOCOMOTIVE

Oklahoma City, M., K. & T. Ry. Oklahoma Engine Terminal and Line Revision; M., K. & T. Ry. Eng. News-Rec., vol. 87, no. 11, Sept. 15, 1921, pp. 440–443, 10 figs. Extensive improvements cover terminal and freight facilities and new entrance to city. Novel turntable. Coal, ash and water-softening plants.

TEXTILE MILLS

Air Conditioning. Air Conditioning in Textile Mill (in Japanese), Masanosuke Yanagimachi. Jl. Soc. Mech. Engrs., Tokyo, Japan, vol. 24, no. 69, June 1921, pp. 11–23, 3 figs.

TIDAL POWER

Utilization. The Utilisation of Tidal Power, with Special Reference to the Severn Estuary, F. C. Lea. Engineering, vol. 112, no. 2907, Sept. 16, 1921, pp. 424–426, 8 figs. Writer summarizes preliminary work and investigations necessary before decisions are come to, relative to use of tidal estuaries for power purposes. Paper read before British Assn.

Transmission of Electrical Energy and Tidal Power, T. F. Wall. Engineer, vol. 132, no. 3431, Sept. 30, 1921, p. 345. Brief preliminary outline of system obviating difficulty of varying speeds of turbines, and permitting use of a.c. generators driven directly from turbines. (Abstract.)

TIME STUDY

Foundries. Time Studies in the Foundry, A. G. Peter. Indus. Management, vol. 62, no. 4, Oct. 1921, pp. 244–250, 3 figs. Describes method of graphic analysis of molding work, and its successful operation at Chain Belt Co., Milwaukee, Wis.

Stop-Watches. More Jobs for the Factory Stop-Watch—I. Factory, vol. 27, no. 4, Oct. 1921, pp. 473–475, 1 fig. Describes development of stop-watches and different types which are available for different industrial uses.

TOOL MAKING

Analysis of Production. Analysing Tool Production Problems. Eng. & Indus. Management, vol. 6, no. 14, Oct. 6, 1921, pp. 370–373, 9 figs. Describes method of analysis and gives results of alternative methods of machining and set-up.

TRACTORS

Cletrac. Smaller Tractor Added to Cleveland Line, J. Edward Schipper. Automotive Industries, vol. 45, no. 10, Sept. 8, 1921, pp. 454–457, 6 figs. Describes the "Cletrac" built by Cleveland Tractor Co.; weighs 1820 lbs. and can plow 6 to 8 acres a day; can perform other farm tasks.

TRADE UNIONS

Influence on Production. Some Thoughts on Modern Trade Unionism—II, Edward Brown. Eng. & Indus. Management, vol. 6, no. 9, Sept. 1, 1921, pp. 237–239. Its influence on production.

Modern. Some Thoughts on Modern Trade Unionism—IV, V and VI, Edward Brown. Eng. & Indus. Management, vol. 6, nos. 11, 12 and 13, Sept. 15, 22 and 29, 1921, pp. 296–298, 320–322 and 356–358. Sept. 15: Discusses share of trades unions in control of industry. Sept. 22: Relation to individual worker. Sept. 29: Is trade unionism the means or the end?

TUBING

Steel. Investigation of the Effect of the Ratio of Diameter to Gage Thickness Upon the Torsional Strength of Steel Tubing. Air Service Information Circular, vol. 3, no. 263, July 20, 1921, 11 pp., 6 figs. Research of investigation showing that modulus of rupture of thin wall steel tubing varies with relation to diam./thickness.

V

VENTILATION

Air Filtration in Buildings. A Study of the Infiltration of Air in Buildings, F. Paul. Jl. Am. Soc. Heating & Ventilating Engrs., vol. 27, no. 6, Sept. 1921, pp. 671–676, 5 figs. Supplementary to report by O. W. Armspach in same journal (Jan. 1921), explaining fundamental principles of experiments being conducted, methods followed, etc. Present report contains explanation of several changes and refinements introduced and report of 25 tests conducted in seven different rooms in five different buildings.

VISCOSIMETERS

Atreco Air-Bubble. Air Bubble Viscosimeter, Victor R. Abrams, Joseph T. Kavanagh and Charles H. Osmond. Chem. & Met. Eng., vol. 25, no. 14, Oct. 5, 1921, pp. 665–666, 1 fig. Describes "Atreco" viscosimeter constructed on the principle that the rate of gravitational upward movement of an air bubble in a liquid is a function of the viscosity of the latter.

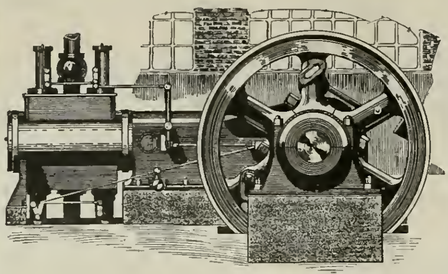
Balances for. The Bifilar Windbalance, A. F. Zahm. Jl. Franklin Inst., vol. 192, no. 2, Aug. 1921, pp. 233–237, 3 figs. For delicate measurement of air resistance along stream, in a wind tunnel. Practical usefulness.



No "Back Talk" from the LENTZ Poppet Valve ENGINE

Springfield, Massachusetts,
November 1, 1921.

Erie City Iron Works,
Erie, Pa.

Gentlemen:

In reply to your favor of the 31st ultimo relative to the Lentz Engine which you installed in our Springfield plant in January 1920, we beg to advise that it is a pleasure to say the engine is very satisfactory.

We are carrying almost a continuous overload of from 20 to 25 percent and there is not any of the "back talk" that we have experienced with other types of poppet valve engines. On the whole we find it quite easy to operate and very economical in steam consumption.

Very truly yours,
THE WILLIAM CARTER COMPANY,
(Signed) Walter Prouty, Chief Engineer.

Every experienced mechanical engineer will appreciate what Mr. Prouty means when he says that he has never had any "Back Talk" from his Lentz Engine. Freedom from the various annoyances that are common with less perfectly constructed engines means a great deal added to the operating efficiency of the entire plant,

Remember, too, that Lentz Engines are very economical of steam; give close regulation; and maintain their original efficiency for an almost unlimited period of years if properly taken care of.

A very complete and well-illustrated catalogue describing the Lentz Engine will be sent promptly on request.

Manufacturers Agents and Distributors for lines possessing unusual features or exceptional excellence which conserve fuel, labor, or industrial costs.

10 HIGH STREET BOSTON, MASS.

Let us make three SUGGESTIONS

During this period of post-war re-adjustment, there is a natural tendency to put off buying mechanical equipment except that which is absolutely required; and also to consider *price* rather than *quality* when forced to buy. In this connection, we say "don't" in three suggestions.

DON'T use old machinery that is badly worn. DON'T buy cheap, rather than, good machinery. DON'T buy important machinery without consulting a competent engineer.

Experience has shown us that it is neither economical or safe to do any of these three things; and we advise and serve our clients thoroughly.

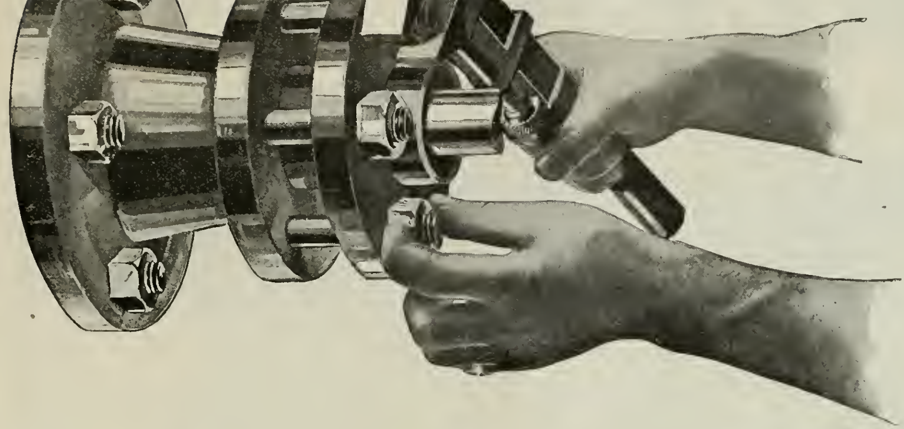
gland nuts than forcing them with a wrench—a way that makes both rod and packing last longer. Read about it.



How do you pull up gland nuts?

With a wrench?

WHEN you pull up gland nuts tight with a wrench, you may stop leakage. But when you've stopped the leak, the packing grips the rod tighter than before—the only reason why inert packing packs at all. But the power required to force the rod through tightly jammed packing and the resulting destructive wear are often more expensive than the leak.

Why not just finger-tight?

You need and should only make the gland nuts finger-tight when you use Johns-Manville Sea Rings. This is because gland pressure is not required to force the Sea Ring against the rod. Sea Rings do not press against the rod except when there is a tendency to leakage past them. But the instant pressure starts to escape a part of each Sea Ring automatically presses against the rod with a force that is proportional to the tendency of leakage—only maximum when necessary, and this maximum is always the minimum required to prevent leakage.

Let the Packing do the Work Automatically

Sea Rings' pliant lips, automatically touching the rod only when necessary to prevent leakage, ease away automatically as the pressure drops.

It's much more economical to pack automatically, with the gland nuts merely finger-tight—just enough to retain the packing in the stuffing box.

Stop needless rod friction with Sea Rings

Sea Rings save power and largely prevent rod and packing wear. For they press against the rod only when the pressure requires it. That's why Sea Rings outlast ordinary inert packing. Ask the nearest Johns-Manville Branch for the Sea Ring Booklet.

The Engineering Societies Library

One of the largest collections of engineering literature in the world is that found in the Engineering Societies Library, 29 West 39th Street, New York.

It comprises 150,000 volumes, including many rare and valuable reference works not readily accessible elsewhere. Over 1,300 technical journals and magazines are regularly received, including practically every important engineering journal published in the civil, mechanical, electrical, and mining fields.

The library is open from 9 a. m. to 10 p. m. with trained librarians in constant attendance. Its resources are at the service of the engineering and scientific public

A Heine Waste-Heat Boiler in process of installation

Heine Waste-Heat Boilers

can be profitably used in such plants as employ any of the following furnaces for industrial operations:

- Open-Hearth Steel Furnaces
- Rotary Cement Kilns
- Puddling Furnaces
- Malleable-Iron Melting Furnaces
- Coal-Gas Benches
- Oil Stills
- Glass-Melting Furnaces
- Soda-Ash Furnaces
- Zinc, Copper, Nickel, etc. Refining Furnaces
- Miscellaneous Heating Furnaces

Wherever conditions permit the installation of Heine Waste-Heat Boilers it is possible to increase substantially the thermal efficiency of the primary furnace. In fact, the economy effected by the **utilization** of the waste heat from the primary furnace for steam generation is often sufficient to pay the cost of the installation in a few years.

Inasmuch as there are many modifying conditions affecting the proper design of boilers of this type, such as raw materials, fuel, operating characteristics of the primary furnace, etc., each installation requires individual study to determine the feasibility of the plan and the best methods of application. The Heine Boiler Company will be glad to answer in detail any inquiries of this nature.

Green Stokers Last Longer

Industrial engineers investigate three phases of the mechanical equipment which they propose to install in their factories:

Correctness of operating principle.
Materials used in construction.
Workmanship employed.

They have learned that equipment embodying the correct operating principle is limited in length of service only by the materials used and workmanship employed.

Since the patenting of the first chain grate stoker in the United States in 1848 the operating principle of burning coal progressively with continuous ash discharge has never changed.

Materials used and workmanship employed in Green Chain Grate Stokers insure longest service. They set the standard for the boiler room —your steam factory.

Hundreds of Green Chain Grate Stokers that have been in use from fifteen to twenty years have been modernized and are delivering results comparable with new installations.

Write to Department M for information on how Green Chain Grate Stokers meet every factory standard.

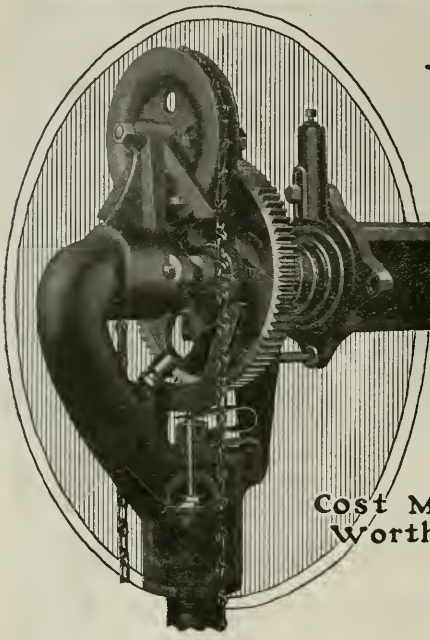
40 to 50% Saving on Labor and Steam

DIAMOND VALV-IN-HEAD SOOT BLOWERS



Cost More Worth More

Important mechanical features of the Diamond Valv-in-Head soot blower are: Monel metal valve seat and disc; full floating construction permitting movement of the unit in any direction; control of speed through reduction gearing; ease of operation due to ball thrust bearings, etc., etc.

COST of labor and steam are two important items in soot blower operation. Note how the Diamond Valv-in-Head cuts these costs in half:

LABOR—

(a) The total time required for blowing is cut squarely in two.

(b) There are no lost steps and no lost time between opening of valve and operation of unit.

(c) Only one man is required, no matter how large the boiler. (With other types of blower heads two men are customarily employed on large boilers).

Under these conditions the cost of labor for cleaning boilers is comparatively small.

STEAM—

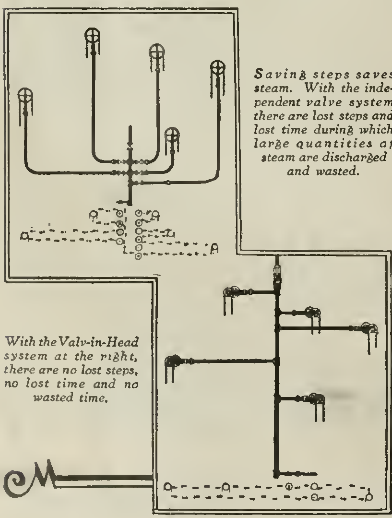
(a) Steam jets are revolving throughout the entire blowing period.

(b) Speed of rotation is controlled by gear reduction. No waste of steam occurs as the result of too slow or too rapid operation.

(c) Globe valves, essential to other heads, require many valuable moments to open and close, during which steam is wasted. The automatic operation of the Valv-in-Head eliminates losses.

The saving in steam with the Valv-in-Head is pronounced, because every bit of steam does effective work in cleaning the boiler.

These are only two of eleven important advantages of Diamond Valv-in-Head soot blowers. Others include savings in pipe, valves and fittings, maintenance, gain in cleaning efficiency, etc., etc.



Saving steps saves steam. With the independent valve system there are lost steps and lost time during which large quantities of steam are discharged and wasted.

With the Valv-in-Head system at the right, there are no lost steps, no lost time and no wasted time.

Every boiler needs a mechanical soot blower and you will save money by buying the best. Ask for your copy of Bulletin 237 describing the new blower.

SOOT BLOWERS - SAVE 4 to 8% FUEL

WORKING DATA

FOR ENGINEERS

AND PURCHASING AGENTS

EVERY member of The American Society of Mechanical Engineers (prior to October 1, 1921) should by this time have received, free of charge and postpaid, one copy of the 1921 volume of Condensed Catalogues of Mechanical Equipment. New members desiring to purchase copies, and old members desiring additional copies, are entitled to a special price of $3.00, plus 25 cents for carrying charges.

A limited number of copies are available, also, for sale to non-members at $4.00 per volume (plus 25 cents for carrying charges); and all such orders will be filled as received so long as the supply lasts.

Engineers, draftsmen, purchasing agents, and all others who are concerned with the design, selection, or buying of mechanical equipment will find in this volume a considerable fund of useful working data, arranged under four principal heads as follows:

(1) 648 pages of Condensed Catalogue data covering the products of 495 leading American manufacturers; all conveniently arranged in standardized form; liberally illustrated; and containing so far as circumstances permit complete tables of dimensions, capacities, weights, etc.

(3) A Classified Table of Contents, which enables its user to turn at once to that section of the book in which is contained catalogue data on the desired subject.

(2) A 233-page Mechanical Equipment Directory or "Buyers' Guide" in which the principal products of 4,000 manufacturers are classified under 3,000 headings, with page reference in all cases where the firms listed have published condensed catalogue data.

(4) A Directory of Consulting Engineers, in which the names and addresses of 1,000 engineers are classified under 400 subject headings.

Volumes Sent on Approval

So that there need be no hesitation about ordering the volume, because of possible misapprehension as to the precise nature of its contents, a copy will be delivered to any member of The Society or subscriber to Mechanical Engineering, subject to approval, as specified on the attached coupon. The percentage of books returned to us after such examination has been so small as to be almost negligible—a striking testimonial to the fundamental value of the work. Please use the coupon in ordering.

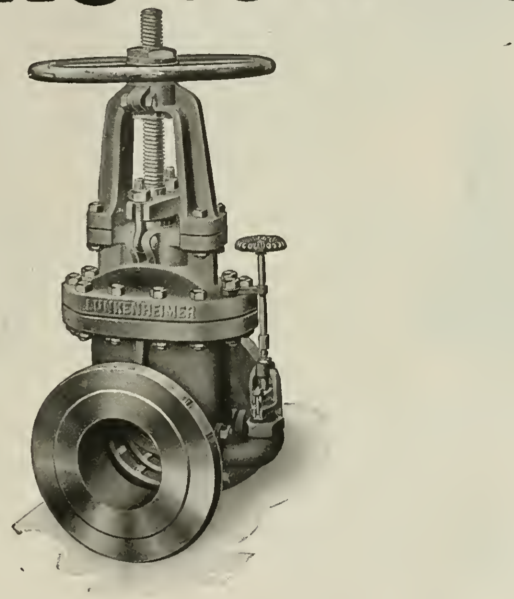
LUNKENHEIMER
"Victor" Gate Valves



Dependable performance is the service record of LUNKENHEIMER "VICTOR" Gate Valves. The "VICTOR" solid wedge disc, double-faced and guided in its travel, is the most practical design of Gate Valve construction. It eliminates "dragging" across the seatring faces and the consequent wear prevalent in valves employing loose parts.

Highest quality materials, coupled with the LUNKENHEIMER method of manufacture; bearings bronze bushed to minimize wear; the indestructible gasket between the bonnet and body flanges and all parts, including the seatrings renewable, all tend to enhance their value and insure longevity.

Made of Iron, bronze mounted, in both Inside Screw Stationary Stem and Outside Screw Rising Stem types, in four weights for pressures ranging from 100 to 250 pounds. Also in Quick-opening Sliding Stem type for pressures from 125 to 50 Pounds, depending on the size.

"VICTOR" Gate Valves are also made in Bronze for pressures up to 250 pounds, and in Cast Steel for pressures up to 350 pounds and temperatures to 800 deg. F.

Specify LUNKENHEIMER "VICTOR" GATE VALVES and insist on their installation.

"A Valve in the Line is worth Two Under Repair"

Unless a valve is positively dependable and will remain tight for long periods without attention it represents a poor investment.

Pratt & Cady Renewable Valves are a worthwhile economy in times where every effort is made to reduce the cost of doing business. When after long hard service or because of scale, or other similar substances in the line, leaks develop, the worn parts can be repaired without removing the valves from the line and in minimum time.

Gate valve wedges are reversible and the discs of globe, angle and check valves, as well as seat rings in all types of valves, are renewable. No tool more complicated than a spanner wrench is needed to make the replacement.

Pratt & Cady Valves are economical in both first and final cost. You cannot afford to install any other kind.

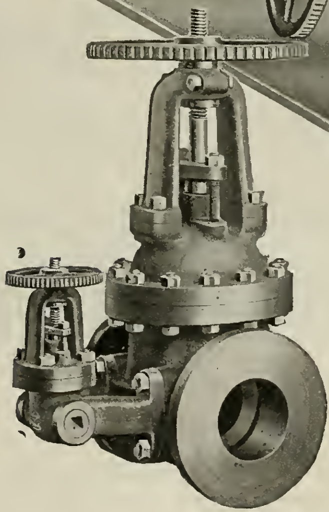
Jenkins E. H. Iron Body Gate Valve with by-pass, one of several of the type installed in the Atlantic Building, New York City.



Flanged, 204-B

Jenkins Extra Heavy Iron Body Gate Valves

Built throughout for heavy pressures and high temperatures and especially adapted to meet the requirements of modern high pressure power plants.

The valves are of the double face, solid wedge type and are made either with inside screw, stationary spindle, or outside screw, rising spindle.

Shape and the distribution of metal are such as to not only insure castings entirely free from internal and shrinkage strains, but also to secure perfect rigidity and resistance to the severe stresses incident to the service for which they are recommended.

Suitable for working pressures of 250 pounds steam or 400 pounds water. Made with screwed or flanged ends, and with or without by-pass, as ordered.

Genuine Jenkins Valves are known by the name and Jenkins "Diamond Mark"—and are obtainable through supply houses everywhere.

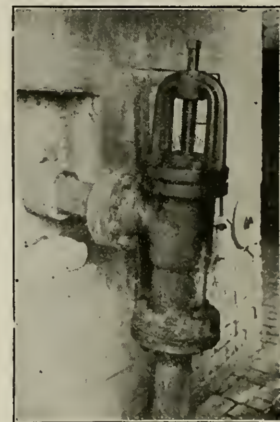
10 Years' Daily Blow-Off Service Without Repacking



The illustration—made from an unretouched photograph—shows a 3-inch angle flanged YARWAY SEATLESS BLOW-OFF VALVE in the plant of the Consumers Power Company, Cadillac, Mich.

This valve was installed in 1911, has been in continuous daily service ever since, and has never been repacked.

The engineer says it looks good for ten more years.

Do you experiment—or do you buy blow-off valves of proved worth?

Many power plants now use Yarway Seatless and Yarway Double Tightening Valves in tandem, where two valves are required on each blow-off line.

Conveying Abrasive Material

Cast Iron Pipe

The greatest copper reclaiming plant in the world is that of the Calumet & Hecla Mining Co., on the shores of Torch Lake, an arm of Lake Superior. Fifty million tons of mill tailings, which have accumulated here during the past 50 years, and now being dredged and pumped out through the two lines of cast iron pipe shown here, at the rate of thousands of tons, daily, to the tanks in their ammonia leaching plant. No other pipe has been found to withstand this severe service so well.

A partial list of our automatic steam specialties.

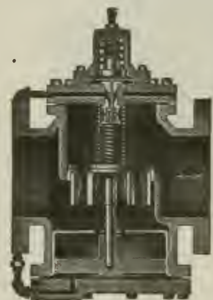
Beginning at the boiler with the **Non-return Pilot Valve** that closes in case of rupture to either power piping or boiler.

High and Low Water Alarm indicating when not enough water or too much is in the boiler.

Feed Water Controlling Device to maintain constant water level in high pressure boilers.

Damper Regulator to control draft dampers.

Pressure Reducing Valves from high to medium or above vacuum. Also for water, gas or air.



Kieley High Pressure Pilot Regulating Valve

Combination for controlling engine and draft for mechanical stoker fired boilers.

Steam Separators and Traps.

Oil Separators and Grease Traps.

Back Pressure Valves, enabling the use of exhaust steam for heating purposes.

Pump Governor to return condensation from high and low pressure returns direct to boilers.

Exhaust Heads, Blow-off and Drip Tank Controllers.

Temperature Controller for hot water tank.

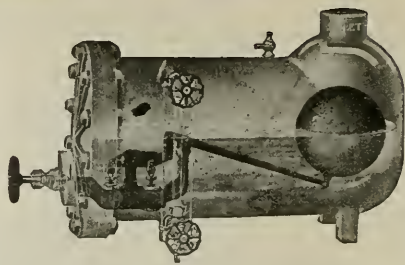
Combination Pump Governor and Lever Float Valve for keeping water supply tank filled.

Low Pressure Boiler Water Feeders and Damper Regulators.

Lifting and Return Traps to return condensation back to boiler where radiators or coils are set below same.

Our catalogue and further information regarding your requirements are at your service.

(*See Our Data in* 1921 A.S.M.E. Condensed Catalogues of Mechanical Equipment)



Its family name is "Davis"—

You might guess that from the history of the operation of this Davis Steam Trap. For by giving unusually dependable service and long life it exhibits the Davis family traits.

The Davis Steam Trap operates under any pressure without loss of steam. Valves are cone shaped and well balanced. They are isolated from the inlet, so that they cannot be clogged or damaged by incoming foreign matter. Valves and seats are made of durable Tobin bronze—and are renewable. All parts are easily accessible without breaking steam line by removing trap cover.

Write to the G. M. Davis Regulator Co., 439 Milwaukee Ave., Chicago, for the 72 page catalog that describes the complete line of Davis Valve Specialties.

The Engineering Societies Library

ONE of the largest collections of engineering literature in the world is that found in the Engineering Societies Library, 29 West 39th Street, New York.

It comprises 150,000 volumes, including many rare and valuable reference works not readily accessible elsewhere. Over 1,300 technical journals and magazines are regularly received, including practically every important engineering journal in the civil, mechanical, electrical, and mining fields.

The library is open from 9 a.m. to 10 p.m., with trained librarians in constant attendance. Its resources are at the service of the engineering and scientific public.

MEASURING OIL

AND ALL OIL PRODUCTS WITH THE

EMPIRE METER

The most accurate, convenient and efficient method of performing this highly important function of the oil industry.

The positive displacement, oscillating piston EMPIRE oil meter is commended to the attention of all Oil Engineers because of its extreme simplicity, ease of installation and operation and great reliability. We offer every facility for its complete investigation, in factory or actual service.

EMPIRE meters have proved their worth by the test of thirty years of service under a wide range of conditions in every part of the country.

Jones Spur Gear Speed Reducer, with slow speed shaft connected directly to driven shaft by all-metal flexible coupling. Motor speed, 365 r.p.m. Final speed, 30.25 r.p.m. Reduction ratio, 28 1/2 to 1.

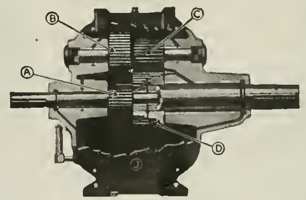
Compact—Simple—Durable

—the Jones Spur Gear Speed Reducer

Although it occupies very little installation space, the Jones Speed Reducer accomplishes reductions up to 200 to one, and over. A typical installation is shown above.

Its simplicity and durability are due to its mechanical correctness—demonstrated in the small illustration on the right. Three countershafts are evenly spaced about the drive and driven shafts, so that transverse loads due to tooth thrust are exactly balanced.

Just plain spur gear drive, with no internal gears or overhanging shafts.



A—Pinion meshes with and drives three gears B. B—Gears are mounted integral with the three pinions C. C—Pinions mesh with and drive slow speed gear D.

Better Machine Tools

Timken performance charts are laid out in years; and the service element in terms of hundreds of millions of revolutions at speeds of more than 3,000 r p m.

No one of the more than 60,000,000 Timken Tapered Roller Bearings now in service has been recommended for its service except on the basis of tried and known performance. Timken Tapered Roller Bearings are applicable in every industry

—because Timken Tapered Roller Bearings perform most satisfactorily where demands both of high speed and heavy load are excessive.

Timken performance is quite readily accounted for because Timken Tapered Roller Bearings

—carry radial loads, thrust loads, and resultant loads continuously and simultaneously

—function uniformly satisfactorily throughout the entire speed and load range

—carry more load per unit space required

—are adjustable for the wear which *must* follow motion.

The Timken Engineering Journal, containing authoritative data on better machine tools of all descriptions, mine equipment, road machinery, electrical equipment, printing presses, pumps, and hundreds of other industrial and machinery appliances, is available upon request

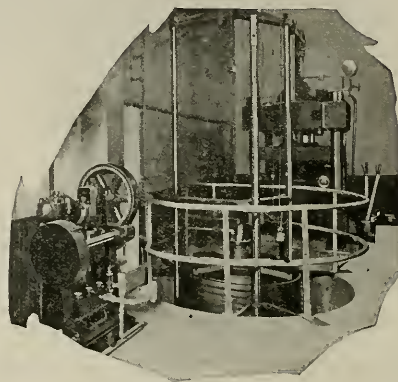
HYDRAULIC EQUIPMENT
For Every High Pressure Purpose

A Difficult Pressing Problem.



The illustration shows a complete H-P-M hydraulic installation,—press, pump, accumulator, valves and fittings, in operation in one of the largest industrial laboratories in the country.

The press shown in background is used for making a special form of metallic briquette. The metal which is in powdered form is placed in a mould. The mould is in two pieces and is not bolted. The base of the press is so designed that a side ram operated hydraulically clamps the mould together and holds it in place while the upper ram exerts a pressure of 500 tons on the material. Both upper and side rams have hydraulic pull back cylinders.

These and similar pressing problems which we have solved, guarantee our ability to meet your "pressing needs," no matter how out-of-the-ordinary they may be. Tell us what you wish to press. We will submit catalogs, drawings and estimates.

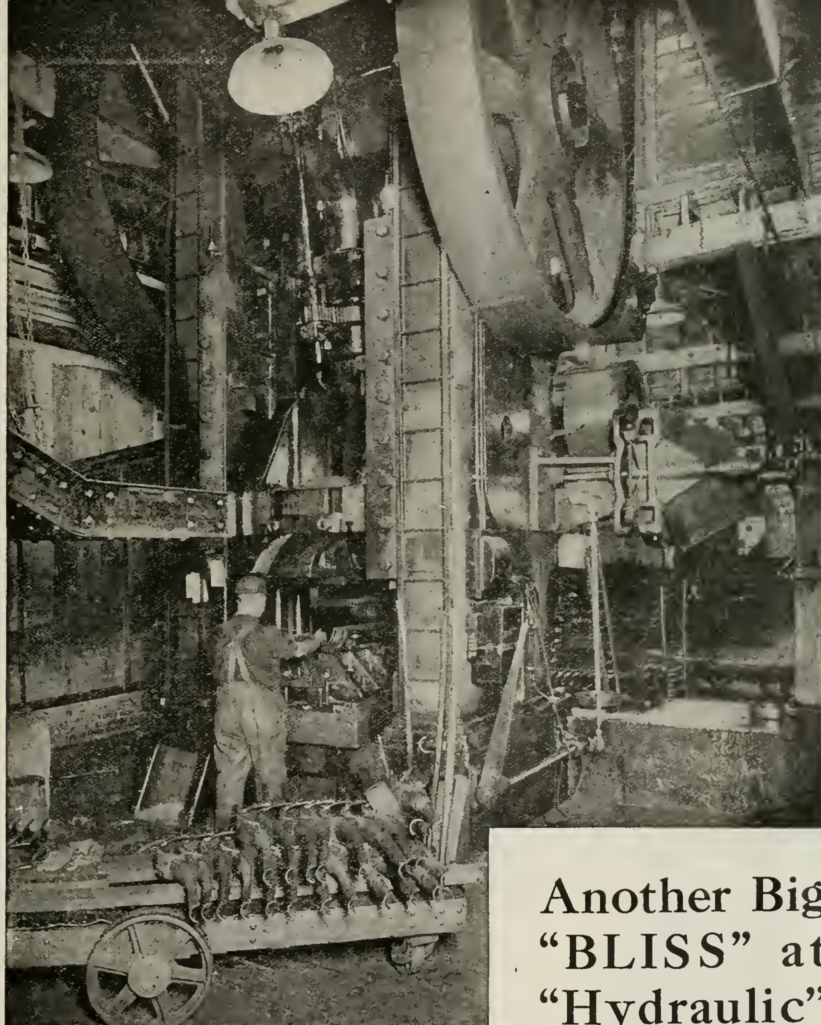
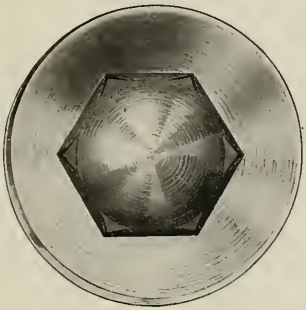
"FOR - YOUR - PRESSING - NEEDS"



The corner triangles in the bottom

Identify—



The 30% Stronger Hollow Set Screw

Look in the bottom of the socket-hole: At the corners are little triangular "pits," left by the hexagon punch in the Allen process of cold-drawing.

First the socket-hole is drilled; you'll see the drill marks on the bottom. Then a solid hex. punch (of the same diameter) fits down into the hole and drives the "blank" through a die, compressing the metal around the hexagon shaft—*forming the socket.*

In the corner triangles the angular edges of the punch leave their mark. And that is the mark of an Allen screw; essential evidence of the Allen process; your guide in getting the right article.

This doesn't tell you much about the advantages of USING "Allens," but we'll gladly send you an interesting booklet that will (not forgetting the price list!).

BUY IT FROM THE NAVY

Naval Vessels as Hulks for Salvage

By Sealed Proposals opening January 16, 1922
At Board of Survey, Appraisal and Sale,
Navy Yard, Washington, D. C.

Improvements in Naval construction have rendered these fine old warships obsolete, and the opportunity is now being given the metal trades to purchase for salvage the following vessels:—

Some of the Vessels Offered for Salvage

(Note.—Displacement given below is for full load.)

U. S. S. MAINE (Battleship). Built in 1901.
Length, 393 feet; draft, 23 feet; beam, 72 feet.
Displacement, 13,500 tons. Now at Philadelphia, Pa.

U. S. S. MISSOURI (Battleship). Built in 1901.
Length, 394 feet; draft, 24 feet; beam, 72 feet.
Displacement, 13,500 tons. Now at Philadelphia, Pa.

U. S. S. WISCONSIN (Battleship) Built in 1898.
Length, 374 feet; draft, 24 feet; beam, 72 feet.
Displacement, 12,150 tons. Now at Philadelphia, Pa.

*U. S. S. BROOKLYN (Cruiser). Built in 1895.
Length, 402 feet; breadth, 65 feet; draft, 24 feet.
Displacement, 10,068 tons. Now at Mare Island, Cal.

*U. S. S. COLUMBIA (Cruiser). Built in 1892.
Length, 413 feet; draft, 23 feet; beam, 58 feet.
Displacement, 7,387 tons. Now at Philadelphia, Pa.

U. S. S. MEMPHIS (Cruiser). Built in 1903.
Length, 504 feet; draft, 25 feet; beam, 73 feet.
Displacement, 15,712 tons.
Now a wreck at Santo Domingo, D. R.

TARGET (Ex-Monitor PURITAN). Built 1882.
Length, 299 feet; draft, 18 feet; beam, 60 feet.
Displacement, 6,060 tons. Now at Norfolk, Va.

U. S. S. OZARK (Monitor). Built in 1900.
Length, 225 feet; draft, 13 feet; beam, 50 feet.
Displacement, 3,356 tons. Now at Philadelphia, Pa.

TARGET (Ex-Monitor MIANTANOMOH). Built in 1876.
Length, 263 feet; draft, 14 feet; beam, 55 feet.
Displacement, 3,990 tons. Now at Norfolk, Va.

U. S. S. TONOPAH (Monitor). Built in 1900.
Length, 255 feet; draft, 13 feet; beam, 50 feet.
Displacement, 3,356 tons. Now at Philadelphia, Pa.

*U. S. S. SMITH (Destroyer). Built in 1909.
Length, 294 feet; draft, 8 feet; beam, 26 feet.
Displacement, 902 tons. Now at Philadelphia, Pa.

*U. S. S. ALBERT BROWN (Fish Boat). Built in 1897.
Length, 103 feet; draft, 10 feet; beam, 18 feet.
Gross tonnage, 108 tons. Now at Philadelphia, Pa.

U. S. S. ORIOLE (Ex-DALE); Wooden Sailing Vessel. Built in 1839.
Length, 117 feet; beam, 34 feet.
Now at Coast Guard Depot (S. Baltimore, Md.)

NOTE.—The vessels marked with an asterisk (*) will on December 15, 1921, be offered for sale for "Conversion to Commercial Uses." Such vessels as are not sold on that date will be offered on January 16, 1922, for sale as "Hulks for Salvage."

The offer of these vessels by the Navy Department for sale to commercial organizations should be considered from the standpoint of a nucleus to go into the ship breaking up field for some *"farsighted concern" looking for new business.*

Aside from the ferrous and non-ferrous metals entering into Naval ship construction, consider the electrical machinery, pumps, winches, boilers, engines, piping, etc., for which there is always a receptive market with an attractive recovery.

A careful investigation of the success recently achieved in foreign countries by *"ship breaking"* concerns will convince you of the advisability of promptly communicating with the Navy Department.

Write or wire for catalog No. 27-46b giving the terms of sale and describing the vessels offered.

(Patented)
Section showing deflection of hot gases, *with induced air toward the furnace, for protection of the operator*, and the preheating of air for combustion.

When men are idle, expensive equipment and buildings are also idle.

In past summers, the unbearable heat that caused prolonged shutdowns in many forge shops was **often due to faulty forges or improper application and utilization of the heat.**

To relieve these conditions, progressive forge shops are installing Rockwell Economizer Forges.

These forges enable the men to *work steadily and in comparative comfort*. They also afford other advantages in the way of *decreased operating cost, better quality of product*, and *decreased floor space*.

Bulletin 239-U, dealing with improved methods of heating and handling material, layout of equipment, and other factors influencing the cost of production, may be had by writing to our nearest branch.

W. S. ROCKWELL COMPANY

Furnace Engineers and Contractors

ANNEALING TWIST DRILLS IN NICHROME CONTAINERS

NICHROME CONTAINERS IN PLANT OF BEARING MFR

Higher than Price

Economy is in Force

uniform results in the heat-treated parts, but Nichrome Containers cut the cost by reducing spoilage, by shorter heats, by greater furnace capacity, and by less fuel consumption throughout their long life of usefulness.

Nichrome Containers are guaranteed for thousands of furnace hours at 1800° F. Their life is remarkable. For example:—in the treatment of ball bearings the average life of the retort which Nichrome replaced was five weeks; Cast Nichrome has been in use for 3 years and is still in good condition. In this case more than thirty times longer life—to say nothing of other advantages. That's true economy for you— cost saving of the most practical sort. We'll be glad to furnish further proof; simply give us the word.

Announcement

In order that we may serve the Ice and Refrigerating industry more fully we are now furnishing the trade with either the Ammonia Compression or Absorption type of Ice-making and Refrigerating equipment. After a thorough investigation we selected the

Ingersoll-Rand

as the latest, best, and most efficient Ammonia Compression machine.

Our sales engineers will be very glad to solve your refrigerating problems and aid you with their experience in the selection of the type of machine your conditions demand. Correspondence is invited and bulletins will be sent upon request.

At the new Prices

you cannot afford to be without a **K & E 20 INCH SLIDE RULE** for your desk!

Its longer scales enable you to obtain greater accuracy in your calculations, with easier reading than is possible with the smaller, pocket-size rules. Just the right size for your desk.

Improved methods of production make possible this substantial reduction of our prices on all 20 inch rules. *Send for booklet showing our Slide Rule Assortment.*

K & E 20 inch Slide Rules

4051	Mannheim	$ 14.00
4053-5	Polyphase	16.00
4088-5	Polyphase Duplex	20.00

Complete in case, with Directions.

THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS

29 West 39th Street, New York

Cards Continued on Next Page

CLASSIFIED ADVERTISEMENTS

Classified advertisements in MECHANICAL ENGINEERING are inserted at the rate of 40 cents a line; 30 cents a line to members of A.S.M.E. Eight words to the line average. Minimum insertion charge, 5 line basis; maximum 20 lines. No display matter carried. ***Copy must be in hand not later than the 6th of the month preceding date of publication.***

The following are some of the BUSINESS OPPORTUNITIES available through the Engineering Business Exchange, Charles Whiting Baker, Director, 30 Church Street, New York City.

AN AUTOMATIC VENDING MACHINE which rejects slugs and defective coins has been developed ready for manufacture and it has been demonstrated that a very large market awaits it. The Brooklyn (N. Y.) syndicate owning this machine want a partner who will take an executive position and invest $25,000.

A CLOTH MEASURING MACHINE for use in retail dry-goods stores, has been developed by a well known member of the A. S. M. E., and is already in successful use in one of the largest Department Stores. Investigation shows there is a very large market for this at a good profit. Business will be sold outright to manufacturer able to market machine on a large scale.

VACUUM JAR suitable for carrying solid food as well as liquids; easily kept clean and sanitary. About 20,000 already made and sold. Especially adopted for lunch kits for school children, workmen, etc., and for touring. Much less fragile than Thermos bottle. Made by automatic machinery, fully protected by patents. Cost of production very low. This is an opportunity for an enterprising manufacturer or business man to develop an industry of large proportions.

MANUFACTURERS seeking profitable products to make and sell, or seeking competent men to take executive position with the purchase of a part interest, or owners of profitable business properties desiring outright sale, will find advantage in using the service of the Engineering Business Exchange, Charles Whiting Baker, Director 30 Church Street, New York City. Circular describing the service of the Exchange, which is a clearing house for Business Opportunities, mailed on request.

MECHANICAL ENGINEER, member of the Society, with long years of experience in the Chemical and Sugar lines and Commercial Engineering, desires representations for the Metropolitan section. Well experienced in handling Export business also. Address EX-383, care this Journal.

EXECUTIVES who can command a salary of from $2,500 to $25,000 and upward who are alert to grasp greater opportunities to communicate with us. Our dignified confidential services place you in a position of having responsible employers bid for your services. This without the slightest embarrassment and without jeopardizing your present connection in any way. Business Survey Corporation, Business Counsellors, Buffalo, N. Y.

OXYHYDROGEN and Oxyacetylene devices, manufacturing rights for sale. Will negotiate with manufacturers possessing selling organization or with selling agency having manufacturing connections. Clients must be able to finance themselves while conducting selling operations. Address EX-378, care this Journal.

VACUUM TOOLS. Ready to negotiate with manufacturers having selling organization or selling agency with or without manufacturing connections, for exclusive American manufacturing or selling rights to new line of vacuum tools of merit. Devices include caulkers, hammers, riveters, punches, etc. Address EX-379, care this Journal.

HYDROCARBON ENGINE PATENT—For Sale, outright or on royalties. We were just allowed a patent on an automobile engine and valve mechanism of very simple construction with many technical advantages. Compactness, lightness, simplicity, durability and power are its main features. Could be utilized for aviation and marine purposes to advantage. Address EX-380, care this Journal.

FOR SALE OR DEVELOPMENT: We have the patents of a Power Transmission Mechanism for automobiles, which has been tested in a reliable Mechanical Engineering Laboratory. Parties interested in buying the patent outright or manufacturing on a royalty basis address EX-381, care this Journal.

SALES ENGINEER, with New York office, will represent manufacturer on commission basis. Address H. B. Prindle, 70 East 45th Street, New York, N. Y.

MANUFACTURERS, ENGINEERS, INVENTORS: In our consulting practice we are frequently so situated as to be able to associate manufacturers, who require additional capital for the conservative expansion of going concerns; or engineers and inventors, who are seeking capital to manufacture articles of merit, or who would sell outright or upon a royalty basis, with reliable parties having capital to invest. For detailed information regarding the opportunities our service affords for placing your developments before such interests, address Ex-374, care this Journal.

EXECUTIVE MANAGER. A machine and tool factory in New England, engaged at present on a contract which will last a number of years, desires to get more business to fill unoccupied space. It will employ as general manager at a good salary and a percentage of profit an executive who can bring new and additional business into the factory. The plant is highly efficient and up to date and is operated on a low overhead. Address EX-375, care this Journal.

EXECUTIVES AND JUNIOR EXECUTIVES—COMMERCIAL, EDUCATIONAL, TECHNICAL. Business is swinging back to normal. Do not wait until Personnels are again complete, all desirable positions filled. Let us negotiate in your behalf with hundreds of employers with whom we are in constant contact. Without obligation on your part write for details of our confidential personnel intermediary service. Business Survey Corporation, Business Counsellors, Buffalo, N. Y.

FOR SALE: A fine opportunity for any firm wishing to go into the manufacture of Hydraulic Machinery. Full line of patterns, drawings and patents, together with the connection for high class tools. Owner's reputation A-1, wishing to retire. Price and terms very reasonable. Address Wm. H. Wood, Engineer's Club of Philadelphia.

CAPITAL WANTED to finance a valuable idea. Advertiser also solicits consultation, designing, drafting, translation of metric plans, and commercializing of patentable ideas. Will work at your office or his own. John B. Mayo, 17 Cole Street, New London, Conn.

MECHANICAL ENGINEER, established manufacturer of staple gas appliances, has developed a small device along these lines which has brought countrywide attention. The yearly consumption of these is tremendous. Patentee seeks responsible associate to finance production. Investment moderate. Address EX-367, care this Journal.

DUST COLLECTOR. Have developed a dust collector of centrifugal type which produces almost perfect separation of dust from air. Machine will handle various materials including the very fine dust found in flour mills. It is simple in construction and lends itself to quantity production. Seven claims have been allowed by the U. S. Patent office. This patent is offered for sale on a cash and royalty basis. Address EX-382, care this Journal.

EXECUTIVES—Confidential negotiations conducted with tact and dignity for professional positions. Engineering and administrative executives are courteously invited to send name and address only for literature describing my direct, successful method. Charles Clark, P. O. Box 141, Newark, New Jersey.

MECHANICAL ENGINEER, with large acquaintance and connections throughout central Ohio, experienced in selling and contracting, desires connections as local representative with concerns wishing to extend their sales or services. Retainer salary and commission or straight commission. H. M. Bush, 16 South Third Street, Columbus, Ohio.

IF YOU WANT NEW PRODUCTS to manufacture, consult me. I sell or place on royalty only worth-while patents that possess commercial possibilities, and can be offered at a reasonable price. W. D. T., P. O. Box 201, Hartford, Conn.

EUROPEAN REPRESENTATIVE. American Consulting Engineer, residing abroad, wishes to represent two or three American manufacturers, as point of contact with engineering developments in Europe. Long training in production and automobile lines. Address EX-199, care this Journal.

Classified List of Mechanical Equipment
Manufactured by Firms Represented in MECHANICAL ENGINEERING

FOR ALPHABETICAL LIST OF ADVERTISERS, SEE PAGE 112

Accumulators, Hydraulic
* Hydraulic Press Mfg. Co.
Mackintosh Hemphill Co.
* Hydraulic Press Mfg. Co.
* Niles-Bement-Pond Co.
* Worthington Pump & Mchy. Corp'n

Aerial Tramways
(See Tramways, Wire Rope)

Air Compressors, Receivers, etc.
(See Compressors, Receivers, etc., Air)

Air Conditioning Apparatus
* American Blower Co.

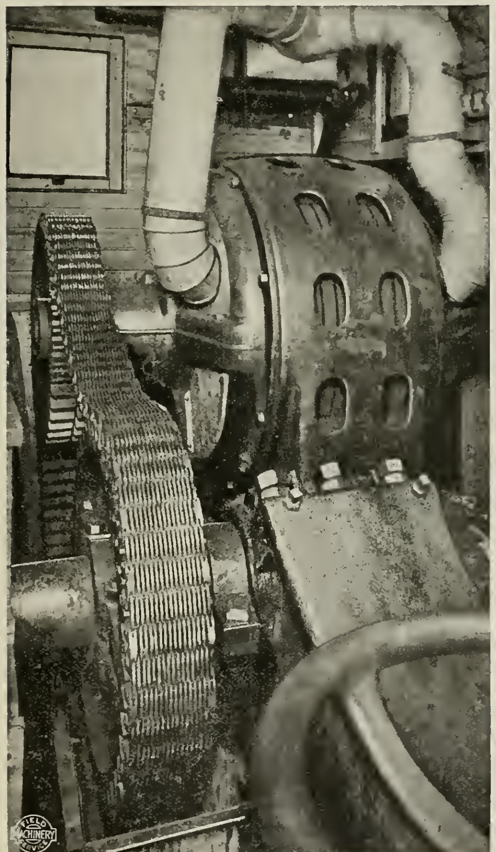
MORSE DRIVES

SILENT CHAIN

THE MORSE "ROCKER JOINT"



Let us tell you more about them

This 125 H. P. MORSE CHAIN Drives 20 Dry Dock Plunger Pumps

Photo and data come from a well-known Eastern shipyard. The twenty pumps are located on a 1200 ton dry-dock and connected to the 125 H.P. motor through Morse Drives. This installation has been in operation for over a year and the man in charge of it says "it's a very good chain and has saved us a lot of trouble."

Our inspector in making his last report recently said he found the chain practically as good as new.

Morse chains transmit 99% of power, are silent, durable and economical to maintain. They have eliminated driving troubles for many well-known concerns and our engineers will tell you exactly what they will do for you.

MORSE CHAIN CO., LARGEST MANUFACTURERS OF SILENT CHAINS IN THE WORLD **ITHACA, N. Y.**

De Laval multi-stage pump with casing cover removed.

Centrifugal Pump Perfection

LIKE perfection in any of the many difficult arts which look easy to the outsider, perfection in the building of centrifugal pumps is compounded of an accumulation of exact knowledge and long and extended experience.

The unequalled efficiencies obtained by De Laval centrifugal pumps (one recently showed over 86% under official test) have been attained only through consistent experimenting and testing. De Laval centrifugal pumps are carefully tested as to capacity, efficiency and running qualities, and it is thus possible for our Engineering Department to note the effects of every change in design.

High efficiency is further effected by the use of De Laval labyrinth wearing rings, which reduce to a minimum the leakage from the discharge to the suction chamber.

Every De Laval centrifugal pump is fully guaranteed. If you will state the proposed conditions of operation, our engineers will promptly give you the benefit of suggestions based upon an extensive experience, and will quote results which we are prepared to guarantee.

Ask for our new Centrifugal Pump Catalog B58

The Engineering Societies Library

One of the largest collections of engineering literature in the world is that found in the Engineering Societies Library, 29 West 39th Street, New York.

It comprises 150,000 volumes, including many rare and valuable reference works not readily accessible elsewhere. Over 1,300 technical journals and magazines are regularly received, including practically every important engineering journal published in the civil, mechanical, electrical, and mining fields.

The library is open from 9 a. m. to 10 p. m. with trained librarians in constant attendance. Its resources are at the service of the engineering and scientific public.

* Lunkenheimer Co.
* Pratt & Cady Co. (Inc.)
* Schutte & Koerting Co.
* Yarnall-Waring Co.

Valves, Non-Return
* Crane Co.
* Crosby Steam Gage & Valve Co.
  Davis, G. M. Regulator Co.
* Ford Regulator Corp'n
  Golden-Anderson Valve Specialty Co.
* Illinois Engineering Co.
* Jenkins Bros.
* Kieley & Mueller (Inc.)
* Lunkenheimer Co.
* Nelson Valve Co.
* Pratt & Cady Co. (Inc.)
* Schutte & Koerting Co.

Valves, Plug
* Homestead Valve Mfg. Co. (Inc.)
* Pratt & Cady Co. (Inc.)

Valves, Pop Safety
* Ashton Valve Co.
* Crane Co.
* Crosby Steam Gage & Valve Co.
* Lunkenheimer Co.

Valves, Pump
* Goulds Mfg. Co.
* Jenkins Bros.
* Johns-Manville (Inc.)
* Richardson-Phenix Co.

Valves, Radiator
* Crane Co.
* Jenkins Bros.
* Lunkenheimer Co.
  Plant Engrg. & Equip. Co. (Inc.)
* Pratt & Cady Co. (Inc.)

Valves, Reducing
  Davis, G. M. Regulator Co.
  Elliott Co.
* Ford Regulator Corp'n
  Golden-Anderson Valve Specialty Co.
* Kieley & Mueller (Inc.)
  Plant Engrg. & Equip. Co. (Inc.)

Valves, Regulating
* Crane Co.
  Davis, G. M. Regulator Co.
* Ford Regulator Corp'n
  Golden-Anderson Valve Specialty Co.
* Illinois Engineering Co.
* Kieley & Mueller (Inc.)
* Lunkenheimer Co.
  Plant Engrg. & Equip. Co. (Inc.)

Valves, Relief
* Ford Regulator Corp'n
  Golden-Anderson Valve Specialty Co.

Valves, Relief (Water)
* Ashton Valve Co.
* Crane Co.
* Crosby Steam Gage & Valve Co.
  Golden-Anderson Valve Specialty Co.
* Lunkenheimer Co.

Valves, Safety
* Crane Co.
* Crosby Steam Gage & Valve Co.
* Jenkins Bros.
* Lunkenheimer Co.

Valves, Stop & Check
  (See Valve, Non-Return)

Valves, Superheated Steam (Steel)
* Crane Co.
  Golden-Anderson Valve Specialty Co.
* Illinois Engineering Co.
* Jenkins Bros.
* Lunkenheimer Co.
* Nelson Valve Co.
* Pratt & Cady Co. (Inc.)
* Richardson-Phenix Co.
* Schutte & Koerting Co.
* Vogt, Henry Machine Co.

Valves, Throttle
* Crane Co.
  Golden-Anderson Valve Specialty Co.
* Jenkins Bros.
* Lunkenheimer Co.
* Nelson Valve Co.
* Pratt & Cady Co. (Inc.)
* Schutte & Koerting Co.

Valves, Vacuum
  Plant Engrg. & Equip. Co. (Inc.)

Ventilating Systems
* American Blower Co.
  Cleveland Blow Pipe & Mfg. Co.

Vibration Indicating Machines
  Vibration Specialty Co.

Vises, Bench
  Prentiss Vise Co.

Vises, Pipe
  Prentiss Vise Co.

Vises, Woodworking
  Prentiss Vise Co.

Voltmeters
* Bristol Co.
* Genera Electric Co.

Vulcanizers
* Bigelow Co.

Water Cinder Mills
  (See Mills, Cinder, Water)

Water Circulators, Filters, Gages Heaters, Meters, Strainers, etc.
  (See Circulators, Filters, Gages, Heaters, Meters, Strainers, etc., Water)

Water Columns
* Ashton Valve Co.
* Kieley & Mueller (Inc.)
* Lunkenheimer Co.

Water Purifying Plants
  International Filter Co.
* Scaife, Wm. B. & Sons Co.

Water Softeners
  Brinckerhoff, H. Gordon Co.
* H. S. B. W.-Cochrane Corp'n
  International Filter Co.
* Permutit Co.
* Scaife, Wm. B. & Sons Co.
* Yarnall-Waring Co.

Water Tube Boilers
  (See Boilers, Water Tube)

Water Wheels
  (See Turbines, Hydraulic)

Waterbacks, Furnace
  Green Engineering Co.

Waterproofing Materials
* Johns-Manville (Inc.)
  Texas Co.

Wattmeters
* Bristol Co.
* General Electric Co.

Welding and Cutting Work
  Linde Air Products Co.

Welding Equipment, Electric
* General Electric Co.

Wheels, Car
* Fuller-Lehigh Co.

Wheels, Polishing Paper
  Rockwood Mfg. Co.

Whistles, Steam
* Ashton Valve Co.
* Brown, A. & F. Co.
* Crane Co.
* Crosby Steam Gage & Valve Co.
* Lunkenheimer Co.

Winches
* Brown Hoisting Machinery Co.
* Lidgerwood Mfg. Co.

Wire, All Metals
  Driver-Harris Co.

Wire, Brass and Copper
* Roebling's, John A. Sons Co.

Wire, Flat
* Roebling's John A. Sons Co.

Wire, Iron and Steel
* Roebling's, John A. Sons Co.

Wire and Cables, Electrical
* General Electric Co.
* Roebling's John A. Sons Co

Wire Cloth
* Caldwell, H. W. & Son Co.

Wire Mechanism (Bowden Wire)
* Gwilliam Co.

Wire Rope
  (See Rope, Wire)

Wire Rope Fastenings
* Lidgerwood Mfg. Co.
* Roebling's, John A. Sons Co.

Wire Rope Slings
* Roebling's, John A. Sons Co.

Wiring Devices
* General Electric Co.

Wrenches
* Greene, Tweed & Co.
* Roebling's, John A. Sons Co.

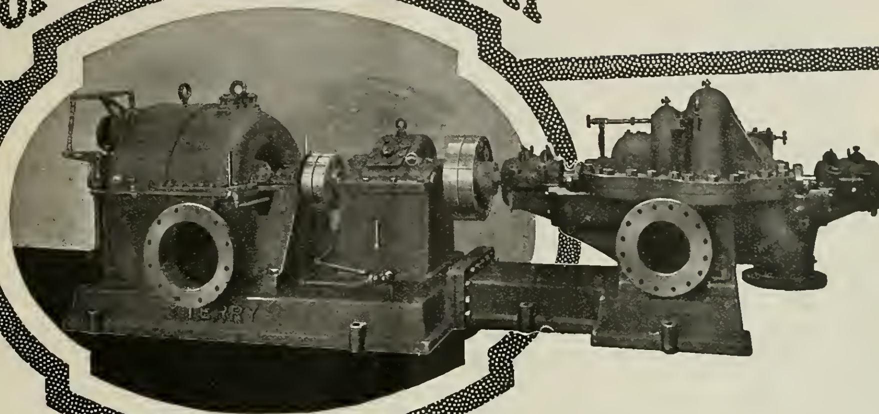
For Driving That PUMP



TURBINE drive permits extreme flexibility of control and also avoids provision against detrimental overloading which is necessary with motor driven centrifugal pumps. As it is impossible to overload a Terry Turbine, any difficulty of this sort is avoided for, as the power demand increases, the speed of the turbine is lowered, thereby automatically compensating for a decrease in the discharge head.

The above illustration shows a geared condensing turbo pump unit for water works service.

You will combine high efficiency, reliability, small space and low upkeep cost in your pump unit, if you specify—

T-740

THE TERRY TURBINE

Offices in Principal Cities in U.S.A. also in Important Industrial Foreign Countries

The Terry Steam Turbine Co.
Terry Sq. Hartford, Conn. U.S.A.
